In the Prussian campaign of 1806 and 1807 he performed many brilliant achievements; and in 1808 he accompanied Napoleon in the Peninsular campaign, and had the command of the third corps of the army, and defeated Castanos (November 23, 1808). Lannes was afterwards appointed to the chief command of the army besieging Saragossa. The details of this remarkable siege are eloquently and graphically described in General Napier's 'History of the Peninsular War,' vol. ii. c. 2.

On the breaking out of the second war with Austria, Lannes had the command of the second corps of Napoleon's army, composed of 50,000 men. In the battle of Essling, while resisting the attack of the Austrians, a cannon-ball carried away the whole of his right leg and the foot and ankle of the left. He lingered for nine days in great agony, and died May 31, 1809.

LANNION. [CÔTES-DU-NORD.]

LANSDOWNE, HENRY PETTY-FITZMAURICE, third MARQUIS OF, an English statesman, was born at Lansdowne House, London, in 1780. He received his early education at Westminster School.

Like the late Lord Palmerston, and his successor Earl Russell, Lord Henry Petty was sent for a period to Edinburgh, and placed under the tuition of the celebrated philosopher Dugald Stewart. Edinburgh was then a nursery of intellectual and political Liberalism. Lord Henry afterwards proceeded to Trinity College, Cambridge, where he graduated M.A. in 1801, and in the following year entered Parliament as M.P. for Calne. He turned his attention to finance, and on Pitt's death, in January, 1806, he became chancellor of the exchequer in the administration of Lord Grenville. At this time he represented Cambridge University, and from 1807 till his succession to the marquise in 1809 he sat in the House of Commons as member for Camelford. He was one of the leaders of the Whig opposition in the House of Lords till 1830, when he accepted office under Lord Grey as Lord President of the Council, which office he held in both the ministries of Lord Melbourne, and again under Lord Russell from 1846 to 1852. He then resigned office, and also the leadership of the House of Lords, which he had held since 1841; but consented to hold a seat without office in the Aberdeen cabinet, and again in the first administration of Lord Palmerston.

During his long political career the marquis of Lansdowne consistently advocated those various measures of progress and reform which he lived to see triumphant. He was a liberal patron of literature, science, and art. The poet Moore, in recognition of long kindness, dedicated to him the collected edition of his works. Lord Lansdowne died at Bowood, on January 31, 1863. He left a splendid library, and one of the finest collections of pictures and statuary in the kingdom. Had he been ambitious, he might have been prime minister more than once, and he is known to have refused a ducal coronet.

LA'NSIUM, a genus of the natural family of *Meliaceæ*, which produces one of the highly esteemed fruits peculiar to the Malayan Archipelago, though unnoticed in many works where we might expect to find it fully described. The fruit is of an agreeable taste, according to Marsden, though the skin contains a colouring juice, extremely bitter, and which is apt to taint it if not opened with care.

LANTANA, a genus of plants of the natural family of *Verbenaceæ*. It has often been stated that they are confined to America; but one species is found in Arabia, and two in India. Piso states that three species, which are confounded together in Brazil under the name of *Camara*, are there used for making medicated baths for diseases of the skin. *L. macrophylla* is employed in infusions as a stimulant, and *L. pseudo Thea* as a substitute for tea.

LANTERN, in Architecture. [SKYLIGHT.]

LANTERN FLY (*Fulgora lateraria*), a species of homopterous insect, belonging to the family *Fulgoridæ*. It was long believed that this fly emitted a brilliant light in the dark; but this does not seem to be the case. The lantern flies are closely related to the *Cicadas*. In most the forehead is prolonged into a narrow snout; the antennæ are placed under the eyes, and the ocelli are two. The Chinese lantern fly (*Fulgora candelaria*) is a well-known form; few cases of insects reach Britain from China in which it does not form a part.

LANTERN, MAGIC. [MAGIC LANTERN.]

LAOCOON, according to ancient fable, was the son of Priam (according to others, of Antenor), and a priest of Apollo during the Trojan war. While offering, in the exercise of his office, a bullock to render Neptune propitious to the Trojans, two enormous serpents issued from the sea, and having first destroyed his two sons, whom he vainly endeavoured to save, attacked Laocoon himself, and, winding themselves round his body, crushed him to death in their folds. This dreadful punishment was inflicted by the goddess Minerva for the part Laocoon had taken in endeavouring to dissuade the Trojans from admitting into Troy the fatal wooden horse, which the Greeks had consecrated to Minerva.

An enduring celebrity has been gained for this story from its forming the subject of one of the most remarkable groups in sculpture which time has spared to us. It represents the agonized father and his youthful sons, one on each side of him, writhing and expiring in the complicated folds of the serpents. The figures are naked, the drapery that is introduced being only used to support and fill up the composition. This superb work of art originally decorated the baths of Titus, among the ruins of which it was found in the year 1506. The names of the sculptors who executed it are also recorded. They are Agesander, Polydorus, and Athenodorus, natives of Rhodes. (Pliny, xxxvi. v.)

With respect to the date of the work, the most careful consideration seems to fix these sculptors as late as the early emperors; and Lessing, whose work on the Laocoon deserves the attention of all who take an interest in the philosophy and capabilities of art, believes they lived in the reign of Titus.

This group is justly considered, by all competent judges, to be a masterpiece of art. Intense mental suffering is portrayed in the countenances, while the physical strength of all the three figures is evidently sinking under the irresistible power of the huge reptiles wreathed around their exhausted limbs. One son, in whose side a serpent has fixed his deadly fangs, seems to be fainting; the other, not yet bitten, tries to disengage one foot from the serpent's embrace. The father, Laocoon himself, is mighty in his suffering: every muscle is in extreme action, and his hands and feet are convulsed with painful energy. Yet there is nothing frightful, disgusting, or contrary to beauty in the countenance. The whole of this figure displays the most intimate knowledge of anatomy and of outward form. The youths are of a smaller standard than the proportion of the father; a liberty hardly justifiable, but taken probably with the view of heightening the effect of the principal figure. The right arm of the figure of Laocoon is a restoration. The group of Laocoon and his sons is now preserved in the museum of the Vatican at Rome. There are casts of it in almost every European museum.

LAODICEA. [PHRYGIA.]

LAON. [AISNE.]

LAOS comprehends the central portions of the peninsula without the Ganges, lying between 15° and 24° N. lat., and 96° and 103° E. long. It borders on the south on Siam and Cochin China, on the east on the last-mentioned country, on the north on China, on the north-west and west on the Birman empire. The river Saluen divides Laos from Birma;

and the country near it is covered with mountain ranges, which do not attain the snow-line, but rise in some parts to a considerable height. This mountain-region is intersected by wide level tracts and plains along the courses of the rivers, which are of great fertility, but low, and are subject to frequent and extensive inundations. The south-eastern part, traversed by the river Camboja, seems to be more elevated. Along the eastern border of Laos there runs a mountain-range, about 100 miles wide, which separates it from Cochin China and Tonkin. The greatest part of the country is covered with forests and swamps or stagnant waters.

The largest of its numerous rivers are the Saluen [BIRMA], the Mackhaun, or Cambodia, and the Menam, which flows through the centre of the country between the two first-named rivers. It rises on the western declivity of the table-land of Yunnan, in two branches, which unite south of 22° N. lat. From the point of junction to 18° N. lat. the river is called the Maepraen; but from thence to its mouth in the Gulph of Siam it is called the Menam. Its length is 800 miles.

The country produces rice, cotton, tea, silk, gum-lac, and a great variety of fruits and woods. The elephant, rhinoceros, cattle, and buffaloes abound. Gold, silver, copper, tin, iron, and rock salt are the chief mineral productions.

The inhabitants of Laos seem to be the original stock of a nation which is widely dispersed over the peninsula without the Ganges, to the east of the river Saluen. According to Gutzlaff they are mostly inferior in civilization to the Siamese; but yet they have made considerable progress in the various arts of civilized life. They are Buddhists, and their sacred books are written in the Pali language.

Laos is divided into three great portions. The most northern is called Upper Laos; its capital is Kemalatain. South of it lies Lachto, with the capital Changmai. The south-eastern part is called Lanchang, or the country of the Shan. Laos has generally been subject to the neighbouring countries in modern times. The country belongs partly to Birma, Siam, Anam, and China, but it contains tribes which retain independence under their respective chiefs.

Laos carries on an active trade with Siam, Birma, and China.

LAOU-TSZE or LAO-KIUN, an eminent Chinese philosopher, who lived in the sixth century before Christ, was the contemporary of Confucius, and the founder of the Taose or Taou sect, familiar to students of Chinese history as the rivals of the Buddhists. He is said to have lived in solitude, and to have given himself to meditation upon truth and virtue, although he was archivist at the court of the Chinese monarch. It is stated that he left the court and withdrew into some secret place, having, however, first written his celebrated work, 'Tao-tee-King,' or Book of Reason and Virtue. This book has had many commentators, and was translated into French in 1842 by Stanislas Julien.

Laou-tsze died in the twenty-first year of the reign of King Wang of the Chow dynasty, 523 B.C., at the age of one hundred and nineteen. He believed in the existence of a Supreme Being, immaterial, almighty, and exercising universal control; and that man finds

his perfection in identifying himself with this Being, and imitating his eternal and undisturbed quiet. He taught the immortality of the soul, and inculcated the great principles of charity, benevolence, virtue, and the free will, moral agency, and responsibility of man.

The sect still exists in China and Japan, but their moral code has become corrupted by the addition of immoral doctrines and idolatrous practices.

LAPALISSE. [ALLIER.]

LAPIDARY WORK. The work of the lapidary is that of cutting, shaping, grinding, and polishing small hard pieces of stone, especially those which go by the name of gems or precious stones. Such stones require different modes of treatment according to their hardness. The diamond, sapphire, ruby, chrysoberyl, and zircon rank among the very hardest; the agate, amethyst, bloodstone, cornelian, carbuncle, cat's eye, crystal, emerald, felspar, granite, jasper, lapis-lazuli, onyx, opal, sardonyx, serpentine, and topaz, though differing much among themselves in hardness, may be considered as occupying a sort of medium rank; while a softer class is that which includes alabaster, coral, glass, jet, lava, malachite, mother-of-pearl, steatite, &c. It is by means of small revolving wheels that these are cut and polished by the lapidary. The wheels are of iron, lead, wood, and other substances. For cutting, the edge of the wheel is sharp, and is touched with moistened diamond-powder or emery-powder, and then acts like an exquisitely fine saw, which works its way through the hardest gems when applied to it. The grinding is performed on a horizontal lead wheel, charged on its upper surface with emery-powder; the stone to be ground being pressed against it with the hand until it is smooth enough for polishing. In polishing, a tin wheel, or sometimes a wooden one, covered with leather, is used, the polishing material being rottenstone.

One of the most delicate examples of lapidary-work ever executed was the shaping of the world-renowned KOH-I-NOOR; a small steam-engine and a revolving apparatus were made expressly for the purpose, and the great duke of Wellington cut the first facet, as an amateur who took great interest in the matter, a few months before his death in 1852. Elaborate as the arrangements were, the lapidary-work was essentially the same in this as in other instances—the friction of a rapidly-revolving metal wheel moistened with diamond-powder and oil. [CAMEO; GLASS MANUFACTURE; KOH-I-NOOR.]

LAPIS LAZULI. [LAZULITE.]

LA'PITHÆ. [CENTAUR.]

LAPLACE, PIERRE SIMON, was born in March, 1749, at Beaumont-en-Auge, near Honfleur, and was the son of a farmer. He received a good education, and appears at first to have turned his attention to theology; but as early as the age of eighteen he went to Paris, having previously taught mathematics at his native place. He had letters of introduction to D'Alembert; but finding that they procured him no notice from that philosopher, he wrote him a letter on some elementary points of mechanics, with which D'Alembert was so much pleased that he sent for Laplace the same day, telling him that he had found a better way of calling attention to his claims than by letters of introduction. Very shortly after-

towards the recommendation of D'Alembert procured for Laplace a chair of mathematics at the military school of Paris. This took place in 1768 or 1769. In 1772 Laplace showed his powers in a paper on integration of equations of finite differences in the 'Mémoires' of the Academy of Turin; and from that time his scientific life was one achievement after another, until he attained a reputation almost Newtonian with the world at large, and of the highest extent and character among mathematicians, who, though they cannot even compare walks of so different a kind as those of Newton and Laplace, feel that the latter must be named next after Lagrange, and the two together above all the followers of the first.

The political life of Laplace was not so favourably distinguished. In 1799 the First Consul made him minister of the interior. With the views which Napoleon always professed with respect to science, it is not wonderful that he should have made the experiment of trying to strengthen his administration by the assistance of a philosopher whose rising fame made the French expect to claim a name which should rival that of Newton. But the experiment was not successful; and after a very short period the First Consul removed Laplace to the head of the *Sénat Conservateur*. The subsequent account given by Napoleon of his minister will be a part of the biography of Laplace in all time to come. 'A mathematician of the highest rank, he lost not a moment in showing himself below mediocrity as a minister. In his very first attempt at business, the consuls saw that they had made a mistake. Laplace looked at no question in its true point of view. He was always searching after subtleties, all his ideas were problems, and he carried the spirit of the infinitesimal calculus into the management of business.' This pointed satire is not, we suspect, one of which the force will be always admitted; first, because it is so very like what a satirist ought to say of a mathematician; secondly, because the character of Laplace's mathematical writings is signally and ridiculously the opposite of all the preceding. That Laplace was an incompetent minister is probable; but this is not the worst.

In 1814 he voted for the deposition of his benefactor—a step which might have been justifiable on public grounds; but nothing can excuse the suppression of the dedication to Napoleon, which stood at the front of his 'Théorie des Probabilités' during the prosperity of his benefactor, and no longer. Laplace, who had been created a count by Napoleon, and a *marquis* by Louis XVIII. immediately after the Restoration, did not appear at court during the short restoration of the former. Of his political conduct during the Revolution we have no account, except that he was at one time under the suspicion of the authorities, and was removed from the commission of weights and measures.

After the final Restoration, Laplace's only public employments were of a scientific character, and he died on the 5th of May, 1827. His last words were, 'Ce que nous connaissons est peu de chose; ce que nous ignorons est immense.'

The author of the 'Mécanique Céleste,' to use a common synonym for Laplace, must be an object of the admiration of posterity as long as any record of the eighteenth century exists. With the exception

of some experiments made in conjunction with Lavoisier, to determine the quantity of heat in different bodies, we do not find that Laplace was employed in actual experiment. But for many years he was the head though not the hand of European astronomy; and most of the labours of observation were made in directions pointed out by him, or for the furtherance of his discoveries in the consequences of the law of gravitation.

The first two volumes of the 'Mécanique Céleste' appeared in 1799, and may have been the inducement of the First Consul to make Laplace a member of the government. The third volume appeared in 1802, the fourth in 1805, and the fifth in 1825. One posthumous supplement has appeared. Its bulk is about 2000 quarto pages. If all this work had been collected by one man, even from the writings of others, we should have called him the Delambre of the theory of gravitation, and should have prized his writings for their extent, their faithful representation of the state of the science at a particular time, and the diligence displayed in the undertaking. When to the preceding, which is forgotten in the splendour of some of the results, we add that to Laplace is due the discovery of much, the development of more, and that by the employment of his own resources in a manner which takes all the originality and power of the investigator, and the arrangement and combination of the whole, we may begin to see how he has earned his fame.

Laplace explained his discoveries in a work entitled 'Exposition du Système du Monde,' of which the fifth edition bears the date 1824. The account here given is in style and clearness of a superior kind, somewhat too egotistical, and partaking of the disposition to suppress all notice of his predecessors common to the French school of mathematical writers. A similar companion to the 'Theory of Probabilities' was published (fifth edition, 1825) under the title of 'Essai Philosophique sur les Probabilités.' A little treatise, published in 1821, called 'Précis de l'Histoire de l'Astronomie,' afterwards was made the fifth book of the fifth edition of the 'Système du Monde.' His lectures on the elementary branches of mathematics are in the 'Leçons de l'Ecole Normale.'

Of the 'Théorie des Probabilités' we must speak precisely as of the 'Mécanique Céleste,' adding perhaps that there is no part of the latter in which more original power is displayed than in the former. The subject being somewhat isolated, its results are little known; they have, however, been extensively applied to astronomy, both by Laplace himself, and particularly by the German writers.

LAPLAND, the country of the Laplanders, comprehends the northern and north-eastern part of the Scandinavian peninsula from 64° to 71° N. lat., and from the White Sea to the Atlantic.

Lapland probably comprises an area of about 150,000 square miles, of which about two-thirds are subject to Russia, and the other third to Sweden and Norway. Russian Lapland is separated from Swedish Lapland by the river Muonio and the Tornea Elf, and from Norwegian Lapland by the Tana Elf. Russian Lapland is divided between the two governments of Archangel and Uleaborg; in the former it constitutes the district of Kola, and in the second that of Tornea. Swedish Lapland is divided between

the two districts (laens) of Pitea and Umea. Norwegian Lapland is called Finnmarken.

Along the Norwegian coast lies the mountain-range of the Kiölen, which rises in some places to a height of 6000 feet; and nearly the whole distance from thence to the Gulf of Bothnia is bare and sterile. Russian Lapland is an extensive plain, generally covered with sand, but some isolated hills rise on the plain to an elevation of several hundred feet. It has many small lakes and rivers, and forests of stunted trees.

The climate is very cold. Three-fourths of the year the country is covered with snow, and the frost between November and March is very intense. A few days of intensely hot weather occur in July and August.

Four nations inhabit Lapland—the Laplanders, Swedes and Norwegians, Finlanders, and Russians. The original inhabitants, the Laplanders, are mostly located in the sterile districts northward of the polar circle. They are divided into the fisher Lapps of the sea-coast, and the nomade Lapps of the interior. The fishing Laplanders are dispersed among the lakes and along the banks of the rivers, where they live on the produce of their fisheries. The Swedes and Norwegians occupy those tracts which are adapted to agriculture, where they cultivate rye, barley, oats, and potatoes. Barley grows as far north as lat. 70°. But the best pasture grounds and meadows are in possession of the Finlanders. The Russians live in the district of Kola, where they are chiefly occupied as fishermen or as merchants.

Wild animals are numerous, including bears, beavers, wild reindeer, wolves, lynxes, wolverines, foxes, hares, squirrels, martens, otters, and lemmings. Among the birds are eagles, capercaillies, woodcocks, and a variety of sea-birds. The forests, which cover a considerable part of the surface of the country, consist mostly of birch, fir, pine, alder, and aspen.

The estimated population in Norwegian Lapland is 5000; in the Swedish portion, 4000 (Lutherans); in the district belonging to Russia, 8800, who are members of the Greek Church. The Bible has been translated into different dialects of the Lapp language. The country contains only a few scattered villages, the principal, in the Russian portion, being Enontekiis, Enare, and Kola.

The Lapps or Laplanders are physically an ill-developed, diminutive race, with small eyes, low forehead, high cheek-bones, pointed chin, and scanty beard. Men and women dress nearly alike; and in both the straight black hair flows lankly down the back and sides of the head; while the men having little or no beard or whisker, it is hard to distinguish one sex from the other. One half of their time seems spent in killing *ripa* (game) or catching fish, and the other half in eating them, 'their belly being,' according to a recent traveller, 'the only measure.' Many of them are very good marksmen, and regularly supply the large annual markets of Vitangi and Kengis with game and skins, which are sent by Tornea to Stockholm, where they meet with a ready sale. Each man has his house and patch of arable land, a cow or two and a horse, with grass for hay from the river or lake side. Some have a few reindeer, some have none, others three or four hundred, which wander about on the hills, under the charge of a Lapp at the yearly

charge of threepence for each deer. Except in hay-time the men do nothing but fish and shoot, or smoke. Everybody smokes except when eating or sleeping. Their whole life is one of cold, and hunger, and hardship; yet all seem contented. The Lapps wander from place to place in search of pasture for their reindeer, and during these wanderings their sufferings are often very severe. For nearly one-fourth of the year the sun is below the horizon in Lapland, and winter lasts for almost double that time. But in spite of all this, in spite of extreme cold, and, still more, extreme dirt, the Laplander is, as we have just stated, contented. He is dirty, and like most dirty savages fond of finery, and very covetous, but strictly honest. He never takes off his clothes when he sleeps, and never discards his old coat of mangy skin till it drops off, and rarely if ever washes. Yet sickness is almost unknown among the Lapps, and when he takes to his bed it is usually the bed of death. Their dwellings are either conically-shaped mud huts, raised on stakes, and almost impervious to light and air, or hide-covered tents. Their peculiar customs and physical stature keep them completely isolated from the fine-made Norwegian and Swedish peasants.

The most recent work on Lapland is, *A Spring and Summer in Lapland*, by an Old Bushman.

LAPO, ARNOLFO DI, the name by which a very celebrated and one of the earliest of the Italian architects is known. He is so called by Vasari, and is said by him to have been the son of Lapo, a German, whose real name was Jacob. He executed many works in Florence, and died there, according to Vasari, in 1262, aged 68.

LAPPA, a genus of plants belonging to the natural order *Compositæ*, the sub-order *Tubulifloræ*, the tribe *Senectionideæ*, and the sub-tribe *Carduineæ*. *L. minor* has an erect stem, 3 feet or more in height, with many wide-spreading branches. When in flower, the involucre readily breaks from the stalk, and is known in the country by the name of a *Bur*. It adheres to the coats of animals and the hair and clothing of those who pass by, and it is almost impossible to become free from it without breaking the scales asunder and scattering the fruit. It grows in waste places throughout Europe and the west of Asia. *L. major* and *L. tomentosa* are species which are found in Germany and Switzerland.

LAPPS. [LAPLAND.]

LAP'SANA, a genus of plants belonging to the natural order *Compositæ*, the sub-order *Ligulifloræ*, the tribe *Achoraceæ*, and the sub-tribe *Lampsance*. There is only one British species of this genus, the *L. communis*, Nipplewort. It is found in waste uncultivated land, and derives its common name from its reputation in village medicine, as a soothing application to inflamed nipples. *L. fetida* is a species of this genus, which grows in Switzerland and on the Alps.

LAPSE. [ADVOWSON.]

LAPWING. [PLOWERS.]

LARBOARD, a naval term for the left-hand side of a ship, when you stand facing the head. The corresponding term for the right side of the vessel is *starboard*, and from its liability to be confused by the steersman with that word, 'larboard' has been officially abolished in the English navy, and the word *port* substituted.

LARCENY (*Latrocinium*, Latin; *Larcin*, French) is the legal term for theft.

This crime was formerly divided into grand and petty larceny, distinguished by the value of the property taken at the one and the same time. It was grand larceny where the value was more than twelve pence; petty larceny where the value did not exceed that amount: a distinction referable to times in which twelve pence was more than equivalent to as many shillings of the present currency. At common law the punishment of petty larceny was whipping or imprisonment; that of grand larceny was death, unless the offender were in a situation to claim benefit of clergy, of which mode of escaping punishment neither women, nor men who were unable to read, or who had been twice married, or who had married widows, or who, not being actually clergymen, had before taken the benefit of clergy, could avail themselves. [BENEFIT OF CLERGY.] By 4 George I. c. 11, grand and petty larceny were made punishable by transportation. By 7 and 8 George IV. c. 28, the distinction between grand and petty larceny was abolished; and larcenies were then distinguished as Simple Larceny, or Compound Larceny, sometimes called Mixed Larceny.

Larceny at common law is committed by wrongfully taking, against the will of the owner, and carrying away the goods of another, with the fraudulent and felonious intent wholly to deprive him of his property therein.

The taking may be either actual or constructive. It is actual taking against the will of the owner when goods are either taken directly out of the possession of the owner, or out of the keeping of another person who holds them for the owner. Constructive taking against the will of the owner is either where the possession of goods is obtained from the owner with an intention to steal them, in which case the original taking is felonious; or where the owner, without parting with the legal possession, delivers goods into the hands of a person who afterwards converts them to his own use or to some other purpose inconsistent with the continuance of the owner's property in them; in which case such conversion constitutes the felonious taking. The doctrine of constructive taking has given rise to many nice distinctions in the English law, some of which it is not easy to reconcile with the fundamental notion of theft or larceny.

There must not only be a taking, but also a carrying away, technically called asportation; to constitute which the goods stolen must be actually removed from the position which they before occupied. Entire removal, to however slight a distance, is a sufficient asportation. But where a severance is necessary before the thief can have the entire control over the article, the asportation is not complete until such severance is effected; as if goods in a shop are fastened by a string to the counter, or a purse is entangled with keys in the owner's pocket.

The thing taken must be goods; and at common law larceny could be committed only in respect of personal goods. Things real, or things annexed to the soil, technically called the realty, or which are connected with the soil and freehold, were not subjects of larceny at common law. This rule was observed so strictly, that larceny could not be com-

mitted by stealing title-deeds, nor by stealing growing corn, grass, trees, &c., unless severed from the realty by the thief or by the owner, or by a third person, and taken at another time.

The subject-matter of larceny at common law must also have been of things *in possession*, as distinguished from things (technically called *choses in action*, i.e., things which are of no intrinsic value, but are capable of being made available by action or demand, as deeds, bonds, bills, notes, and other securities for money, &c.

The inconvenience arising from these rules, which are adapted to a very different state of society, is remedied by several statutes passed during the last and the present century.

The objection founded upon the connection of the thing stolen with the realty is removed by several provisions of 7 and 8 Geo. IV. c. 29, sec. 23, &c.

The Post-Office Act, 7 Will. IV. and 1 Vict. c. 36, s. 26, makes the stealing and embezzling of post-letters, letter-bags, &c., felony, punishable with a greater or less degree of severity, according to the nature of the offence, and the existence or non-existence of a confidential character in the guilty party.

The goods taken should generally be the goods of another person.

If a man take his own goods, supposing them to be the goods of another, no larceny is committed. But it is larceny if a man takes them for the purpose of fraudulently charging another with the loss; as if a man steal his own goods for the purpose of charging the bailee, or of throwing the supposed loss upon the hundred. If a wife take and convert to her own use the goods of her husband, they being but one person in law, it does not constitute larceny.

The converting of found goods by the finder to his own use does not amount to larceny, unless at the time of the conversion he knows, or has the means of knowing, who is the real owner.

There must be an intent wholly to deprive the owner of the goods stolen of his property therein; which intent constitutes the fraudulent and felonious character of the act.

The statute law relating to larceny was consolidated by the 24 and 25 Vict. c. 96, whereby every larceny is to be deemed of the same nature, and persons convicted of simple larceny are made liable, at the discretion of the court, to be kept in penal servitude for three years, or to be imprisoned for a term not exceeding two years, and if males under sixteen, to public whipping in addition to imprisonment; and the court is empowered to sentence the offenders to be imprisoned and kept to hard labour, and also to direct that they shall be kept in solitary confinement as to the court in its discretion shall seem meet.

As cattle are necessarily left in fields and upon commons and wastes without any person to attend them, the legislature has interfered to protect property of this description by heavier punishments than those inflicted in other cases of larceny.

Stealing from the person of another, whether openly or clandestinely, is a felony punishable by penal servitude for fourteen, or not less than three years, or imprisonment for not more than two years, with or without hard labour. To constitute this offence the thing stolen must be completely removed from the

person of the owner, though such complete removal is not necessary in cases of simple larceny. Robbery from the person with violence or intent to assault is punishable with penal servitude for life, or not less than three years, or imprisonment for two years with or without hard labour.

Breaking and entering any church or chapel (by which is meant a chapel in connection with the established religion) and stealing therein any chattel, or breaking out of any church or chapel after having stolen any chattel therein, is punishable with penal servitude for life, or for not less than three years, or imprisonment not exceeding two years, with or without hard labour and solitary confinement.

Breaking and entering a dwelling-house and stealing therein any chattel, money, or valuable security to any value whatever, is punishable in the same manner. Stealing in a dwelling-house any chattel, money, or valuable security to the value of 5*l.* without a breaking and entering, is now a felony punishable by penal servitude for not more than fourteen or less than three years, or imprisonment not exceeding two years, with or without hard labour. The bailee of any chattel, money, or valuable security, who shall convert it to his own use, is guilty of larceny, and may be convicted thereof upon indictment.

The term larceny is unknown in Scotch law. But in the practice of that country the crime of *theft* may be aggravated by the nature of the circumstances under which it has been committed. [THEFT.] Thus *housebreaking* and *robbery* are both aggravations of theft. [ROBBERY.]

LARCH. [ABIES.]

LARCHER, PIERRE HENRI, born at Dijon in 1726, made himself known by several translations from the Greek classics, the principal of which is his translation of Herodotus, Paris, 1786. In 1774 Larcher published a 'Memoir on the Goddess Venus,' which obtained the prize of the Academy of Inscriptions. He had a controversy with Voltaire, in consequence of some strictures which he wrote on Voltaire's 'Philosophie de l'Histoire.' Larcher was a member of the National Institute. He died at Paris in December, 1812.

LARD. The imports of lard into the United Kingdom in 1865, chiefly from the United States, amounted to 136,898 cwts., value 272,650*l.* The exports in the year 1864 amounted to 33,584 cwts., valued at 75,704*l.* [FATS.]

LARDIZA'BALA, a genus of plants belonging to the natural order *Menispermaceæ*, and named after Michael Lardizala, a Spanish naturalist. This plant is a twining shrub, a native of Chili in woods at Concepcion, also in Peru about Arauco. It has an eatable fruit, which is gathered and sold in the markets of Chili and Peru. The pulp of the fruit is sweet and grateful to the taste.

LARDNER, DR. DIONYSIUS, an industrious scientific writer, was born in Dublin on the 3rd of April, 1793, and died on the 4th of May, 1859. He was educated at Trinity College, Dublin, of which, from 1817 to 1827, he was fellow and tutor; from 1828 to 1840 he was professor of natural philosophy in University College, London. In 1830 he projected a series of manuals of mathematical, mechanical, and physical science, and 134 volumes were published, under the general name of 'Lardner's Cyclopædia,'

between 1830 and 1844, and a second edition in 1853 and following years. Many of the volumes were from his own pen, and these, together with his handbooks of natural philosophy, and a popular exposition of the physical sciences, entitled 'Museum of Science and Art,' are remarkable for their clear style and lucid arrangement.

LARDNER, NATHANIEL, D.D., born 1684, died 1768, was a Presbyterian minister. He studied at Utrecht under Grævius and Burmann, and afterwards at Leyden. He became private chaplain in the family of Lady Treby, who died in 1729, and was a lecturer at the dissenting chapel in the Old Jewry. His 'Credibility of the Gospel History,' the 'Supplement' to it, and his 'Jewish and Heathen Testimonies,' have been considered as the most rational defences of Christianity that had been made up to his time. The most remarkable of his minor publications is his 'Letter on the Logos,' from which it distinctly appears that he was of the Unitarian or Socinian school. The best edition of his works is that by Dr. Andrew Kippis.

LAREDO. [CASTILLA-LA-VIEJA.]

LARES, among the Romans, were household gods; the guardians of their hearths and families. According to Ovid there were generally two, who were sometimes represented with a dog at their feet. Others were clothed in dogs' skins. They usually held a cornucopiæ in their hands as a symbol of good housekeeping. The festival of the Lares was celebrated on the first of May, when they were crowned with garlands, and sacrifices offered to them.

LARGENTIERE. [ARDE' CHE.]

LARGESSE, the money which, in early times, was given to heralds on state occasions for proclaiming the style and title of the sovereign and his nobles. The sums varied from 100*l.* at coronations, to 5*l.* at minor state festivities.

LARGHETTO, a musical term, a diminutive of Largo, slow, but less so than Largo.

LARGO, in music, signifies slow. [ADAGIO.]

LARGS. [AYRSHIRE.]

LA'RIDÆ, the name of a family of birds belonging to the order *Natatores*, and commonly known as Sea-gulls, or Sea-mews.

It is impossible within reasonable limits to follow out the opinions of writers on ornithology relative to the position and genera to be assigned to this family. We can therefore only refer to the writings of Willughby, Ray, Brisson, Lacépède, Meyer, Dumeril, Temminck, De Blainville, Lesson, the Prince of Musignano, Mr. Eyton, and others.

Mr. Vigors (in 'Linnæan Trans.') after commenting on the affinities of the *Laridæ* to other connected families, thus expresses himself with regard to the contents of the family:—

'We enter,' he says, 'the family of *Laridæ* by means of *Sterna*, with which *Rhynchops*, Linn., most intimately accords in habits and external characters, notwithstanding the dissimilitude of the bill. The *Sterna Anglica*, or Gull-billed Tern of Colonel Montagu, conducts us from these genera to the groups which compose the Linnæan *Larus*, now justly subdivided into two genera, the *Lestris*, Ill., and *Larus* of authors. From this group we are led to the genera *Diomedea*, Linn., and *Haladroma*, Ill., which are characterized by the absence of the hind toe, by

means of the species *Larus tridactylus*, Lath., where, though the hind toe is not absolutely deficient, as might be inferred from the specific name, there appears but the rudiment of one, or rather a stump without a nail. The last-mentioned genus, *Haladroma*, originally belonged to the *Procellaria*, Linn., and was separated from it by its tridactyle foot. Even in this character, however, it forms a passage from *Larus* to the groups that compose the genuine *Procellaria*, all of which are distinguished by the singular peculiarity of having no true hind toe, but a nail adhering to the tarsus in its place. We thus arrive at the Petrels, separated into the groups of the *Procellaria*, Auct., *Pachyptila*, Ill., *Puffinus*, Ray, and the section denominated by M. Temminck Les Pétrils Hirondelles. These two latter groups appear to lead us back to the *Terns*, or *Sea-swallows*, from whence we started. The whole of this family, which corresponds with the *Longipennes* of M. Cuvier, is distinctively characterized by the strength and expansiveness of their wings, with the aid of which they traverse immeasurable tracts of the ocean in search of their food, and support their flight at considerable distances from land, seldom having recourse to their powers of swimming. We may thus discern the gradual succession by which the characters peculiar to the order descend from the typical groups that swim and dive well and frequently, but make little use of their wings for flight, to the present groups, which are accustomed to fly much, but seldom employ their powers of swimming, and never dive.'

Mr. Swainson regards the *Laridæ* as a sub-family, consisting of the following genera and sub-genera:—*Sterna* (Terns), including *Sterna*, Linn.; *Thalasites*, Sw.; *Phaeton*, Linn.; *Rhynchops*, Linn.; *Gavia*, Brisson; *Larus*, Linn.; *Lestris*, Ill.; Petrels, including *Procellaria*; *Diomedea*, Linn. [ALBATROSS]; *Haldroma*; *Thalassidroma* (Stormy Petrels); *Pachyptila*; and *Dromas*. For ourselves we do not regard the Petrels and Albatrosses as belonging to the family *Laridæ*. One authority places the Albatross, Petrels, Shearwater, &c., all with nostrils more or less tubular, in a family termed *Procellaridæ*, while his *Laridæ* consist of the True Gulls, the Parasitic Gulls, the Terns, and the Skimmer of the Sea (*Rhynchops*).

In the present article we shall confine ourselves to the Gulls only, including in that term *Xema* of Leach, *Larus* of Linnæus, and *Lestris* of Temminck. The other groups will be noticed under their respective titles.

The Gulls are powerful on the wing, and easy and graceful in their aerial movements; they often rest floating on the water, but they do not dive; yet they skim off floating substances, as dead or living fish, and the putrescent exuvie of the sea, with great address. Some are predatory in their habits, and, like the Sea-eagle, force the more feeble fishers to disgorge their booty. In most species, the plumage undergoes a decided change of colour on the approach of winter, by a process which Mr. Yarrell has proved to be different from that of moulting ('Trans. Zoological Society'). The young differ from their parents, and do not acquire their perfect colouring until the second or third year. The gulls breed in large companies, and in various situations, according to the habits of the species, some selecting the ledges

of cliffs, others choosing flat and exposed rocky islands, while others seek the marshes and pools of the more inland parts, and form their nests among aquatic herbage. These birds have a very wide geographical distribution, and are found in every part of the world, and under a great variety of climate; many, especially of the larger species, are inhabitants of the higher latitudes.

Genus *Xema*.—Bill short, slender, straight, laterally compressed, its tip bent down, the lower mandible somewhat angulated beneath; nostrils lineal; tibiae naked on the lower part; tail forked. In the genus *Xema*, the head becomes entirely or partly of a dark colour, as the season of reproduction approaches, being white during the rest of the year. In the genus *Larus* the head is of an unsullied white during summer, becoming streaked and varied with blackish gray in winter.

Example.—The Black-headed Gull (*Xema ridibundus*), the Laughing Gull of Rennie, the Red-legged Gull of Shaw.

Laughing Gull (*Xema ridibundus*).

This bird is common in our islands, retiring in summer from the sea to breed in inland marshes, after which it returns in flocks to the coast. Its note is a hoarse cackle. Its food consists of fishes, crustaceæ, and the larvæ of coleopterous insects.

Genus *Larus*.—Bill moderate, strong, straight, cultrated, the upper mandible having the tip incurved; symphysis of the under mandible strongly angulated, and ascending thence to the point; nostrils placed in the middle of the bill, lateral, oblong, narrow; tongue pointed, with the extreme tip cloven; wings long, acuminate; tail even, or slightly forked; legs placed near the centre of the body, of mean length and strength, with the lower part of the tibiae naked; feet of four toes, three before and one behind; the three in front united by a membrane, the hind one short and free.

Examples.—The Common Gull (*Larus canus*), the Kittiwake (*Larus rissa*), the Herring Gull, (*Larus argentatus*), the Great Black-backed Gull (*Larus marinus*), the Lesser Black-backed Gull (*Larus fuscus*), and others.

Genus *Lestris*.—Bill moderate, hard, strong, cylindrical, very compressed, hooked at the point, the upper mandible covered with a cere; the under mandible with an angle on the inferior edge; nostrils approaching the front of the bill, diagonal, narrow, closed on their posterior part, and pervious; tarsi

long, naked above the knee; feet with three toes before, entirely palmated; hind toe very small; nails large and hooked; tail slightly rounded, two middle feathers elongated; wings with the first quill-feather the longest.

Black-backed Gull (*Larus marinus*).

Examples.—The Common Skua (*Lestris cataractes*, Temm.), the Pomarine Skua (*Lestris Pomarinus*, Temm.), the Arctic Skua (*Lestris parasiticus*, Temm.).

The Skuas are bold and ferocious birds, natives of the northern latitudes, breeding on wild heaths and solitary islands. They are the determined enemies of the Gulls, and unceasingly persecute them on the wing, in order to force them to disgorge their recently swallowed food, which is caught before it can reach the water. Their flight is strong and rapid.

LARKS, a sub-family of the *Fringillidæ*, thus defined by Mr. Swainson:—Bill more lengthened than in any of the *Fringillidæ*; the tip entire or absolutely notched. Tertial quills considerably lengthened, pointed, and generally as long as the quills. Claws very slightly curved; the claws of the outer toe always shorter than those of the inner toe; hinder claw considerably lengthened, and either nearly straight or very slightly curved. Typical genus *Alauda*. The other genera are—*Calendula*, *Agrodroma*, *Macronyx*, and *Certhilauda*. [FRINGILLIDÆ.]

LARKSPUR (*Delphinium*), a well known genus of plants belonging to the natural order *Ranunculaceæ*, or ranunculus family. The *Upright Larkspur*, much cultivated in gardens, is a native of Switzerland. It is the *Delphinium Ajacis* of botanists.

LARNE. [ANTRIM.]

LARNIKA. [CYPRUS.]

LA ROCHELLE. [CHARENTE-INFÉRIEURE.]

LARREY, DOMINIQUE-JEAN, BARON, was born at Beaudeau, near Bagnères-de-Bigorre, in France, in July, 1766. He studied the elements of medicine and surgery at the hospital at Toulouse, under the direction of his uncle Alexis Larrey, who practised medicine in that city. In 1787 he went to study his profession in Paris, and obtained the appointment of surgeon to the frigate *Vigilante*, in which he visited North America. He returned to Paris at the commencement of the Revolution, and in 1792 joined the French army which was then carrying on its operations on the Rhine. Here he distinguished himself by the invention of the *ambulances volantes*, by means of which the wounded

being first dressed, were carried off the field of battle, even under the fire of batteries. He was at the siege of Toulon, where he became acquainted with Napoleon Bonaparte, who was then a lieutenant of artillery. In 1796 he was appointed a professor in the school of medicine and military surgery at Val de Grace. In 1798 he accompanied the French army with Napoleon to Egypt, and on his return published an historical and surgical account of the expedition, with the title 'Relation historique et chirurgicale de l'Expédition de l'Armée d'Orient en Egypte et en Syrie, 8vo, Paris, 1803. From this time he was advanced to various honourable positions. After the battle of Wagram he was made a Baron of the empire, and in 1812 appointed surgeon-in-chief of the imperial army. He died at Lyons, July 25, 1841. Larrey was a great favourite with Napoleon, who bequeathed to him at his death 10,000 francs, expressing his conviction that 'Larrey was the most virtuous man he had ever known.'

LARRIDÆ, a family of hymenopterous insects, of the section *Fossores*, containing the following genera: 1, *Palarus*; 2, *Tachytes*; 3, *Larra*; 4, *Dinetus*; 5, *Miscophus*.

LARVA, a term applied to that state in which an insect exists immediately after its exclusion from the egg, and which precedes the pupa state. The animals commonly called *Grubs*, *Maggots*, and *Caterpillars*, are larvæ. Grub appears to be a general term analogous to larva; the term maggot is most generally applied to the larva state of Dipterous insects; and caterpillar, in the most common acceptance of the term, is used to designate the larva state of lepidopterous insects. These three terms, however, are used in a very vague manner.

The most striking difference, perhaps, which exists between the larva and the perfect insect, consists in the superior powers of locomotion and consequently better developed skeleton possessed by the latter.

Though larvæ never possess wings, they vary much as regards the development of the locomotive organs, and as these are more or less perfect, so does the larva resemble or recede from the insect in its imago state. Hence Messrs. Kirby and Spence divide larvæ into two sections: those which, in general form, more or less resemble the perfect insect; and those which are unlike the perfect insect. The larvæ of both sections moult, or cast their skin, several times during their progress to maturity. The number of moults varies according to the species, and the period intervening between the moults depends upon the length of the insect's existence in the larva state. In these moults, not only is the whole external covering of the insect cast, but even the lining of the intestinal canal and of the tubes of the tracheæ is shed.

The greater portion of the larvæ of the orders *Orthoptera*, *Hemiptera*, and *Homoptera*, excepting that they have no wings, bear a considerable resemblance to the perfect insect, and hence belong to the first of the sections just mentioned. As, however, the muscles which serve to support and give motion to the wings are attached to the skeleton of the thorax, so, as might be expected, we find this part in the perfect insect more unlike that of the larva perhaps than any other; and again, where (as in the imago state of *Scutellera*) a portion of the

thorax is greatly produced behind and serves to protect the wings when folded, the larva, having no wings, does not possess this peculiarity.

Belonging to the second division, in which the larva does not resemble the perfect insect, are the orders *Hymenoptera*, *Coleoptera*, *Neuroptera*, *Lepidoptera*, and *Diptera*. [INSECTA.]

LARYNX is the organ of the voice. Its framework is composed of five cartilages, which are capable of being moved on each other in various directions by muscles, so as to act upon two elastic bands, on which the voice essentially depends, and which are called the vocal ligaments.

Fig. 1.

1, 1, Os Hyoides; 2, 2, Thyroid Cartilage; 3, 3, Cricoid Cartilage; 4, 4, Arytenoid Cartilages; 5, Epiglottis; 6, Aperture of communication between Glottis and Pharynx; 7, 7, Rings of Trachea; 8, Situation of transverse posterior Muscular Bands; 9, 9, Portion of Trachea cut open from behind.

The first, the thyroid cartilage (2, 2), consists of two plates of dense, tough, fibro-cartilaginous substance, of an irregularly quadrilateral form, united at the lower part of their anterior edges. The prominence of this angular union is felt in the front of the throat, forming what is called the Pomum Adami; at the sides of and behind which the form of the cartilage may be easily traced out with the fingers.

The cricoid cartilage (3, 3) has somewhat the form of a signet-ring. It is inclosed within the angle of the thyroid cartilage, beneath whose lower edge the front and narrowest portion of its ring may be felt, with an interval of about a quarter of an inch between them.

The arytenoid cartilages have each the form of an irregular triangular pyramid (4, 4). They are placed upon the upper edge of the broad part of the cricoid cartilage, just within the most expanded part of the angle formed by the receding plates of the thyroid.

The epiglottis (5) is of a somewhat ovate form. It is attached by its apex to the angle of union of

the plates of the thyroid cartilage, and projects obliquely backwards and upwards over the cricoid and arytenoid cartilages, like a shield, guarding them from the contact of foreign bodies passing from the mouth.

These cartilages are connected chiefly by elastic ligament, which is arranged in bands of varying thickness throughout the whole of the larynx; uniting the upper edge of the thyroid cartilage to the os hyoides, and its lower edge to the cricoid cartilage; passing also from the arytenoid cartilages to the epiglottis, and uniting the rings of the trachea and bronchi; affording to all a firm but yielding connection, and endowing them by its elasticity with the power of resounding in accordance with the vibrations originating in the vocal ligaments.

The vocal ligaments are two narrow bands of highly elastic tissue, stretched between the anterior angle of the thyroid and the anterior surfaces of the arytenoid cartilages. The substance of which they are composed is a yellowish, dense, fibrous tissue, which is placed in those parts of the body where a permanent elasticity is required, as in the spaces between the laminæ of the vertebræ, the coats of arteries, the rings of the trachea, &c. In fig. 2 a profile view of the right vocal ligament is shown:

a, a, a is the outline of the thyroid cartilage, of which part of the left side is removed; *b* is the cricoid cartilage, and *c* the arytenoid cartilage of the right sides; *d, d* is the vocal ligament. In fig. 3 the crico-arytenoidei-laterales (*c*) are shown attached to the cricoid cartilage (*a*), and to the outer angle of the arytenoids (*b*). In fig. 4, the view of the vocal ligaments, *a, a*, is taken as seen from above; they are attached anteriorly to the inside of the thyroid cartilage at *b*, and posteriorly to the front of the arytenoid cartilages *c, c*. Between them is the aperture through which we breathe, the glottis, *d* (fig. 4). It is bounded posteriorly by the inner edges and anterior angles of the arytenoid cartilages; anteriorly by the inner edges of the vocal ligaments. When at rest, as during quiet breathing, the glottis is of a somewhat lanceolate form, but when speaking or singing it is very much narrowed.

The muscles acting on the parts of the larynx

just described are arranged symmetrically, and attached to corresponding points on each side of the larynx; and their names are compounded of those of the cartilages on which they are inserted.

The simplest actions of these muscles in regard to the voice may be thus stated: the crico-thyroid stretch the vocal ligaments; the thyro-arytenoid relax them; the posterior crico-arytenoid open the glottis; the lateral crico-arytenoid and the posterior arytenoid narrow or close it.

Below, the larynx opens into the trachea (fig. 1, 8), which is continued into the chest, and there divides into two branches, the bronchi, whose ramifications and terminations form the air-passages and air-cells of the lungs. The trachea is composed of a series of cartilaginous incomplete rings, which are united behind by muscular fibres, and are connected together by longitudinal elastic bands. It is thus capable of variations both of length, breadth, and tension, and of entering into vibrations with the column of air contained in it, and of assisting in communicating those vibrations through its branches to the walls of the chest.

The larynx has been compared to a variety of musical instruments, and it will be seen that in its different parts it unites the principles of several. In its essential vocal apparatus it most nearly resembles the reed instruments, as the reed-pipes of the organ, the clarinet, &c., or rather a modification of them, in which the vibrating body is not fixed in its dimensions as a metallic tongue, or a reed, but consists of a lamina of elastic membrane, capable of varied degrees of tension, as well as of alterations in its length. No musical instrument has yet been constructed on this principle, unless we consider as such the various kinds of trumpet in which the vibrations are produced by the air impelled against the edges of the lips, rendered more or less tense by the action of their orbicular muscle. The principle has been applied in the formation of artificial larynges by Biot, Cagniard de la Tour, Willis, &c., who have chiefly used caoutchouc membrane; and by Müller and Henle, who have employed besides, either the vocal ligaments themselves or laminæ of the elastic coat of an artery. The most complete examination of the subject is that made by Müller, and published in the first part of the second volume of his, '*Physiologie des Menschen*.'

The notes produced by the glottis are subjected to modifications in timbre, strength, and purity, by the parts connected with the larynx, both above and below the vocal ligaments; but it is difficult to determine the circumstances on which the differences of the timbre of the voice in different persons depend. The difference between the male and female voices is probably owing to the comparative shortness of the vocal ligaments in the latter. According to Müller, their average length in man is $18\frac{1}{4}$ millimètres, in woman only $12\frac{2}{3}$, or nearly as 3 to 2. But to account for the differences of tenor and bass, or of soprano and alto voices, no good evidence has yet been collected. The average compass of the voice is two octaves, but in different parts of the scale in different persons: thus a bass voice commonly has its lowest note four or five notes lower than a tenor, while a tenor has its highest note from four to five notes above the highest note

of the bass voice. A soprano voice again has its lowest note at nearly the same part of the scale as the highest note of a bass voice; and thus the whole compass of the human voice, from the lowest of the bass to the highest of the soprano, would be nearly four octaves. The voices of children resemble very nearly those of women, but in males a remarkable change takes place at puberty, when the voice is said to crack. The change from the shrill treble voice of the boy to the fuller and rounder tone of the man is sometimes perfected almost suddenly; but in most cases it is for some time in progress, wavering between the two extremes, deep and manly during quiet enunciation, but when any exertion is used, suddenly starting up again to the shrill tones of boyhood. In old age, the cartilages of the larynx becoming bony, the ligaments hard and unyielding, and its muscles pale and powerless, the voice completely alters, and it trembles as if there were not sufficient strength in the muscles to maintain a due tension of the vocal ligaments. Besides being subservient to the voice, the larynx fulfils other functions of vital importance to the whole body. In breathing, for example, its exquisite sensibility is immediately excited by the contact of any foreign substance, or of a deleterious gas, and the glottis is firmly closed by the thyro-arytenoid muscles, to prevent the entrance of the noxious body into the lungs. The same action occurs as we swallow each portion of our food, to prevent any of it passing into the lungs; and if a particle by accident touch the glottis, coughing is excited, to insure its speedy removal.

LASCAR, a term signifying 'camp-follower,' but generally applied to those natives of East India who become sailors on board British ships. They make excellent seamen, but are quarrelsome and vindictive, and not to be trusted with management or authority.

LAS CASAS, EMMANUEL AUGUSTIN DIEUDONNÉ, COUNT, a French historian, and one of the companions of Napoleon at St. Helena, was born near Revel, in Languedoc, in 1766. He first entered the navy, and was present at the siege of Gibraltar. At the revolution he fled to England, and served in the expedition to Quiberon. After Napoleon's accession he returned to France, and laboured in the preparation of his admirable 'Historical and Geographical Atlas.' The emperor found out his good qualities, made him his chamberlain, created him a count of the empire, and employed him in inspecting hospitals, prisons, and naval ports. After the battle of Waterloo he begged to be allowed to share Napoleon's exile. While in the island prison, he spared no effort to alleviate the pains of his captive master. At night he jotted down the conversation of the day, and afterwards published the result in eight volumes, entitled 'Memorial de St. Helene,' a work which will always be the chief source of information respecting Napoleon. In 1816 he was sent away from St. Helena, on account of a letter which he contrived to send to Lucien Bonaparte, in which he commented on the treatment of the illustrious exile. After eight months' confinement at the Cape of Good Hope, he came to Europe, and resided in Belgium till Napoleon died, when he returned to France and published his great work; and also memoirs of his own life. Under Louis

Philippe's government he was a member of the Chamber of Deputies for St. Denis. He died 15th May, 1842.

LASER, a highly esteemed gum-resin among the ancients, which had become rare even in the time of Pliny, but which is described by Theophrastus under the name of Silphion. [SILPHIUM.]

LASERPITIUM (the name of the ancient Silphium), a genus of plants belonging to the natural order Umbelliferae. *L. glabrum*, glabrous Laserwort, has roots which are filled with a gum-resin, which is acrid, bitter, and even somewhat caustic. It is said to be a violent purgative. *L. Siler* is a native of the mountains of the middle and south of Europe. The root is extremely bitter, and yields an aromatic resinous substance which has been supposed to be the Silphion or Laser of the ancients. [SILPHIUM.]

LASSO, a rope with a noose at one end, used in South America and other countries for capturing wild horses, &c. It is generally made of a stout thong of hide, and requires much skill in use. Another kind, still more common in South America, is a long cord of skin, with a leaden ball at each end, and is thrown so that when it strikes the leg or neck of the animal, the impetus of the ball causes the lasso to coil round the limb. The lasso has sometimes been used in warfare.

LAST. A last of cod fish, white herrings, meal, and ashes, is twelve barrels; a last of corn is ten quarters, or eighty bushels; of gunpowder, twenty-four barrels; of red herrings, twenty cades; of hides, twelve dozen; of leather, twenty dickers; of wool, twelve sacks; of flax or feathers, 1700 lbs. A last generally is estimated at 4000 lbs.

LASTREA, a genus of Ferns, belonging to the tribe Aspidieae. The following species are British — *L. Thelypteris* (Marsh Fern); *L. Oreopteris* (Sweet Mountain Fern); *L. Filix Mas* (Male Fern); *L. cristata*; *L. rigida*; *L. dilatata*.

LASWARREE, a town of Hindustan, in Delhi, which is celebrated in history as the scene where Lord Lake signally defeated the Mahrattas in November, 1803; when the loss sustained by the British was 800 killed and wounded, and that of the enemy 7000.

LATAKIA. [SYRIA.]

LATANIA, a genus of Palms of the tribe Borasinee of Martius. *L. rubra*, remarkable for its red-coloured leaves, is a native of the Isle of France. *L. rubra* and *L. borbonica* are moderate sized, with all the leaves of a palmate fan shape. The leaves, like those of other palms, are employed by the natives for covering their huts, as well as for making fans and umbrellas. The leaf-stalks are split, and employed for making baskets, sieves, &c.

LATENT HEAT. When a body is exposed to the action of heat so as to change its state, as from a solid to a liquid, it rises to a certain temperature, known as its *melting* or *fusing* point, and remains fixed at that temperature until the whole of that solid shall have been liquefied. The heat applied after the fusing point has been reached does not raise the temperature, but produces the change of state. During this operation a quantity of heat must evidently enter the body in order to produce liquefaction, and as it produces no effect on the thermometer it is said to be *combined* and rendered *latent*,

so that when the body again becomes solid the heat thus *latent* is given off in a sensible form.

A pound of water at 79° Cent. added to a pound of water at 0° Cent. produces of course two pounds of water at 39°·5. But a pound of water at 79° Cent. added to a pound of ice at 0° Cent. produces two pounds of water at 0°. Heat then has disappeared in the production of a change from solidity to fluidity. Since a pound of ice at 0° Cent. absorbs 79° in becoming a pound of water at 0°, it follows that the same quantity of heat is given out or rendered sensible when the water again passes into ice.

The cold of winter is considerably mitigated by the sensible heat which is given out by freezing water, and when the temperature rises with the return of milder weather, a considerable portion of the heat is employed in producing liquefaction.

Similar phenomena accompany the liquefaction of other bodies. When a mass of lead, for example, is put over the fire, it rises to 620° Fahr.; it then begins to fuse, and it remains at that temperature until the whole mass has become liquid; the heat absorbed and rendered latent during the process is called the *latent heat of fusion*. The following table gives the latent heat of certain liquids:—

	Fahr.		Fahr.
Water, ...	142·65	Bismuth, . . .	22·75
Nitrate of soda, .	113·34	Sulphur, . . .	16·85
Nitrate of potash, .	85·26	Lead, ...	9·65
Zinc, ...	50·63	Phosphorus, . .	9·05
Silver, ...	37·92	Mercury, . . .	5·11
Tin, ...	25·65		

It will be seen from the above table that the latent heat of ice is very considerable, while that of lead is very small; hence ice melts slowly, lead rapidly. Ice cannot melt until it has received as much heat as would raise its own weight of water 142·65°, while lead melts with as much heat as would raise its weight of water 9·65°. Did ice melt with the same comparative facility as lead, the first thaw would cause inundations by the sudden melting of the snow and ice of winter.

When a liquid passes into the state of vapour there is a further absorption of heat. During the whole time that water is passing off into the form of steam the thermometer remains fixed; in other words, the steam is of the same temperature as the boiling water. It takes five and a half times as long to convert the water into steam as it does to raise it from 32° to 212°, and therefore the latent heat of steam is $5\frac{1}{2} \times 180 = 990^\circ$. The water has passed through 180° from freezing point to boiling point, and it requires the same heat to be applied to it five and a half times as long as it has already been, in order to convert it into steam, and yet during this time the temperature remains the same.

This enormous quantity of latent heat is again given out when steam condenses into water, and hence steam becomes a powerful source of heat. Indeed, any given weight of water in the form of steam at 212° in being condensed will raise five and a half times its own weight of water from 32° to 212°.

Water furnishes a much larger amount of vapour, bulk for bulk, than any other liquid, a cubic inch of water at 212° expanding to 1696 times its volume, or nearly a cubic foot of steam at the same temperature; whereas a cubic inch of alcohol, boiling at

173°, forms only 528 cubic inches of vapour; ether, boiling at 95°, produces only 298 cubic inches of vapour; and oil of turpentine, boiling at 314°, produces only 193 cubic inches of vapour. Now although the latent heat required to convert such liquids into vapour is much less than that required to convert water into steam, no advantage would be gained in employing them as prime movers, supposing they were as cheap as water, on account of their low expansive force, which must evidently depend on the bulk of vapour produced from a given bulk of liquid.

LATERAN, the name of a church, Basilica Lateranensis, with a palace and other buildings annexed to it, situated at the south-eastern extremity of Rome, near the walls of Aurelian and Honorius. This group of buildings is called 'in Laterano,' from being built on the estate once belonging to Plautius Lateranus. The later emperors had a palace on the spot, and Constantine had a church or chapel annexed to the palace. Constantine, or some of his successors, gave up the palace to the bishops of Rome, and the Lateran, till the beginning of the fourteenth century, was the residence of the popes. The pope, in his quality of bishop of Rome, goes to take solemn possession of it after his election, and he officiates there on certain great festivals, for which reason it is styled the head church in the world, 'Ecclesiarum Urbis et Orbis Mater et Caput.'

A fire broke out in 1808, which consumed the greater part of the palace, as well as the church. The church was restored, but the palace was abandoned, and Gregory XI., when he transferred the papal see to Rome in 1377, fixed his residence in the Vatican palace, which then came to be considered as the residence of the pontiffs till the seventeenth century. Sixtus V., however, in 1586 ordered a new palace (the present structure) to be built, adjoining the Lateran church, and Pope Pius IX. has converted a portion of it into a museum of Christian archaeology. Under a portico on the north side of the church, erected from Fontana's design, stands the *Scala Santa*, or 'Holy Stairs,' consisting of twenty-eight marble steps, which an old tradition states to have belonged to Pilate's house, and to have been the identical ones which Christ descended when he left the judgment seat. They are only allowed to be ascended by penitents on their knees.

LATERITE, in mineralogy, a clayey deposit found in some parts of India and in Ceylon. 'It varies much in colour and composition, but generally consists of a reddish-brown or brick-coloured cellular clay, more or less indurated, and used by the natives as brick, when cut square. It hardens greatly and permanently on exposure, and is well adapted for buildings and fortifications.' Laterite is of Middle Tertiary age.

LATHE. [EARTHENWARE; POTTERY; TURNING.]

LATHE (Sax. *leth*), a part or division of a county, containing three or four hundreds, or wapentakes, according to the laws of Edward the Confessor, as in the counties of Kent and Sussex. *Lathreve* was the name of an Anglo-Saxon officer, who had authority over the third part of the county, according to the number of lathes he governed.

LATHS. In building operations two kinds of laths are in common use. *Slaters' laths* are cut out

of sawn plank, and nailed on to the framework of the roof, for the purpose of receiving the slates or tiles, which are fastened to the laths by nails. *Plasterer's laths* are made by splitting wood, principally Norway spruce fir, in the direction of the grain of the wood. They vary from $\frac{1}{2}$ to $\frac{3}{4}$ an inch in thickness, and are about 3 or 4 feet long. They are nailed upon joists for ceilings, and to the uprights of partition walls, in such manner as to leave a small interval between each lath, into which the plaster may be forced, so as to form a key to support the rest of the work. Upon the Continent oak laths are almost exclusively used.

LATIMER, HUGH, bishop of Worcester, the son of a farmer in Leicestershire, was born about 1472. He took a degree at Cambridge, previous to entering into holy orders. His 'heretical' opinions caused him to be prohibited by the Bishop of Ely from preaching within that diocese, an obstacle which he overcame by gaining the use of a pulpit in a monastery exempt from episcopal jurisdiction. Cromwell, the king's favourite, gave him a benefice in Wiltshire, where he preached reformed doctrines, and recommended him to Anne Boleyn, who appointed him her chaplain, and soon after the bishopric of Worcester was conferred on him (1535). He continued to preach these doctrines for three years, at the expiration of which the Act of the Six Articles was passed, from which he so totally dissented, that he resigned his bishopric.

Accusations were afterwards made against him for his objections to the Six Articles, and he was committed to the Tower. He remained a prisoner for six years; and not until the accession of Edward VI. did he obtain his liberation, when he refused to accept the restoration to his see. Latimer was committed to the Tower soon after the accession of Mary. He steadfastly maintained his opinions, and, October 16, 1555, was led to the stake with Ridley; gunpowder being fastened about his body to hasten his death, it took fire with the first flame, and he died immediately. Latimer published several of his sermons at different times.

LATINI was the name of one of the oldest nations of Italy, who are said to have descended at some remote time, before the building of Rome, from the central Apennines, in the neighbourhood of Reate (the modern Rieti), into the lower country between the Anio, the Tiber, the Alban Mountains, and the sea, which was afterwards called Latium. These Latins appear to have formed their settlements in the lowlands, where they founded many towns—Laurentum, Lanuvium, Lavinium, Aricia, Gabii, Tusculum, Tibur, Præneste, Labicum, Collatia, Cora, and others. That there was a mixture of Grecian blood in the Latin race seems not to be doubted, and a comparison of the elementary parts of the Greek and Latin languages proves at least that those who used these tongues were sprung from or related to a common stock. The Latin communities were united by religious rites.

The Latini are described as a race robust, hardy, frugal, and warlike, and their early union with Rome, great part of whose population was recruited amongst them, contributed mainly to the growth and success of that republic. Their towns were strong, both by their position and their massive walls, traces of which

still exist on the sites of ancient Præneste, Tusculum, and other places of dates anterior to Rome, and are ascribed by some to the Tyrrhenians, who preceded the Latini, and have been confounded with the Pelasgians. The foundation of Alba is involved in great obscurity, but the fact of its being an important town several centuries before the existence of Rome is undoubted. [ALBA LONGA.] Whether Alba was at the head of the Latin Confederation, or was the centre of another confederation distinct from that of the Latins, though connected with it, has been a matter of doubt. Niebuhr adopts the latter supposition. A distinction is made by Livy between the Albans and Latins. The dictator of Alba is not called the dictator of the Latins. The founders of Alba were either emigrants from Lavinium, who built a town and set up an independent state for themselves, according to Livy's story of Ascanius, or they were strangers, probably a tribe from the mountains, who built a new town, which in course of time ruled over part of Latium and sent colonies to Lavinium and other places on the coast which had become deserted. Alba is said to have ruled over thirty colonies, and a like number of thirty towns is mentioned as constituting the Latin Confederation in the Roman period.

Under Tullus Hostilius, the third Roman king, war broke out between Rome and Alba, which ended in the destruction of Alba and the removal of the inhabitants to Rome. In the following reign of Ancus Marcius, the first war of the Latins against Rome is mentioned: the result was that Politorium, Tellene, and Ficana were taken by the Romans, and the inhabitants transferred to Rome, where they were settled on Mount Aventine. Servius Tullius obtained by agreement with the leaders of the Latin cities, what his predecessors could not obtain by force, namely, that the Latins should unite with the Romans in building a temple to Diana on the Aventine, to be common to both people. This was considered as an acknowledgment that Rome was the head of the Latin nation. Tarquinius Superbus, the last of the Roman kings, persuaded the Latins not only to renew the treaty with Rome, but to acknowledge him as their princeps, or chief, and to send their youth to serve no longer as auxiliaries, but mixed with the Romans in the same legion. The history of the Latin cities, after the expulsion of the last king to their subjugation by the Romans, B.C. 337, is a part of the history of Rome. Some of the Latin towns had previously obtained the Roman citizenship, either complete or in a limited degree.

During the second Punic war Hannibal tried to work upon the feeling of dissatisfaction which existed among many of the Latins, as well as other nations of Italy which had been conquered by Rome; and accordingly, after the battles of Trebia and Thrasymene, he separated the Latin and Campanian from the Roman prisoners, and released the Latins without ransom. The Latins, however, unlike the Campanians, Samnites, Hirpini, Lucanians, and others, who went over to Hannibal, remained faithful to Rome, whose armies were repeatedly recruited among them during that long and fearful contest.

The Latins remained for two centuries and a half in the same dependent condition, until the breaking

out of the Social or Italian War. The tribune Livius Drusus proposed that the full Roman citizenship should be extended to them, as well as to the other nations of Italy, which had formed treaties of alliance with Rome. Drusus, however, was murdered, and his motion was dropped for a time. But when the Marsi, Samnites, Peligni, Campanians, and Lucanians rose in arms, and constituted themselves into a confederation, of which they made Corfinium the capital, and after they had defeated several Roman armies, the consul L. Julius Cæsar (B.C. 91) advised and obtained the passing of a law which gave the Roman franchise to all the people of Italy who were allies of Rome and had remained faithful in that emergency. This franchise, or *civitas*, is stated accordingly to have been granted to the 'socii,' or allies, who had furnished their contingents, and to the Latins, who are mentioned distinctly from the rest. By this grant, the freemen of the Latin towns were placed so far on a level with the Roman citizens as to enjoy the full Roman franchise, to be admitted into the Roman rustic tribes, have votes, and be eligible to public offices. Thus the distinction between the Romans and the real or original Latins was obliterated.

LATITAT (Lat. *lateo*, 'to lie concealed'), in Law, the name of a writ calling upon a defendant to answer in personal actions in the Queen's Bench, under the presumption that he is lying hid in some other county.

LATITUDE. [**LONGITUDE** and **LATITUDE**.]

LATITUDINARIAN, in Theology, one who indulges in a latitude of thinking and interpretation in matters of orthodoxy.

LATIUM, the country of the ancient Latins, had at first for its boundaries on the west the Tiber, which divided it from Etruria; on the north, the Anio, which separated it from the Sabini; and on the south, the Tyrrhenian Sea. To the east and south-east its boundaries on the side of the Volsci are not so clear. In the first period of Roman history the Latin territory does not seem to have extended to the eastward beyond the Alban Mount, nor beyond a line drawn from that point to the sea-coast, leaving outside of it Satrium, Corioli, and Antium, which in the earlier ages of the republic appear as Volscian towns. And yet in the first treaty with the Carthaginians, said to have been concluded soon after the expulsion of Tarquinius Superbus, Antium, Circeii, and Tarracina, or Anxur, are reckoned as towns of Latium. Præneste, however, and Tibur appear from the first as Latin towns, the former being the advanced post of Latium on the side of the Hernici, who inhabited the mountainous tract between the Trever (Sacco), the Upper Anio, and the Liris. Tibur, also a town of the Latini, was divided by the Anio from the territory of the Sabini. But the boundary of the Latin territory seems to have crossed the Anio below Tibur, and to have extended across to the Tibur above the influx of the Albia, so as to include the towns of Nomentum and Crustumeria. Within these limits there was a great number of towns, some of which are mentioned in the article **LATINI**.

After the final conquest by Rome of the Volsci, the Hernici, and the Aurunci, the name of Latium was extended to the whole country inhabited by these three peoples, in addition to the country of the old Latins, and this was called Latium Novum.

Under Augustus, Latium and Campania constituted the first of the eleven regions into which Italy was divided by that emperor.

The physical geography of Latium and the actual state of the country are given under **CAMPAGNA DI ROMA**, except the easternmost part of the new Latium, namely, the districts of Gaëta and Sora, which belong to **LAVORO, TERRA DI**.

LATREILLE, PIERRE-ANDRÉ, a distinguished naturalist, was born at Brives, November 29, 1762. He was sent to Paris in 1778, and placed in the college of the Cardinal Lemoine, to be educated for the church. He gained the friendship of Lamarck and other scientific men, and devoted himself particularly to entomological studies. At the Revolution, being an ecclesiastic, he was persecuted and condemned to banishment, but escaped this punishment through the influence of his scientific friends. In 1798 he was named a correspondent of the Institute, and eventually filled the vacant chair of zoology.

Latreille was elected a member of the Academy of Sciences in 1814, and was made in 1821 chevalier of the Legion of Honour. He died at Paris, February 6, 1833.

LATROBITE occurs crystallized and massive. Primary form a doubly oblique prism. The colour is a pale red: the lustre vitreous; and the substance translucent. It consists mainly of silica and alumina.

LATRUNCULI (Lat. *latrunculus*, 'a little thief'), a game among the ancient Romans somewhat similar to our game of chess, which so admirably represented the order and chances of war, that its invention has been attributed to some military officer of distinction. The *latrunculi* were the *latrones* and *calculi*, or chessmen of the game, made of glass or wax, and distinguished by black and white colours. In the Roman classics frequent allusions are made to this game; and a little poem was written upon it, addressed to Piso, which has been attributed to Ovid.

LATTEN. [**BRASS**.]

LAUBAN or **LUBEN**. [**LIEGNITZ**.]

LAUD, WILLIAM, Archbishop of Canterbury, was the son of a clothier at Reading, where he was born, 7th October, 1573. From the free school of his native town he passed, in 1589, to St. John's College, Oxford, where he became first a scholar; then, in 1593, a fellow; somewhat later a reader in grammar; and after he had taken orders, a lecturer in theology. As early as 1601 he revealed his divergence from the theological and ecclesiastical principles which had prevailed in the church of England since the Reformation, by declaring in one of his lectures that the church of Rome had previous to that event been the true visible church of Christ on earth; and in the theses which he defended in 1604 for the degree of bachelor in divinity, he maintained against the Puritans the necessity of baptism as the vehicle of regeneration, and the necessity of the episcopate to the existence of a true church. These views excited great opposition in Oxford, and even drew upon him a formal censure from the university, which was then presided over by George Abbot, afterwards archbishop of Canterbury. In 1608 he was made D.D., and became chaplain to Dr. Neile, bishop of Rochester, who not only gave him several parochial benefices in succession, but introduced him

to the king. James I. had now, from a professed Presbyterian and contemner of the English liturgy, which he had once spoken of to his Scottish subjects as an ill-said mass, become a high Anglican churchman, and Laud was a theologian entirely to his mind. He rose rapidly in royal favour, and though for several years his influence at court was powerfully counteracted by Archbishop Abbot and Lord-Chancellor Ellesmere, this did not hinder his being made, in 1611, a royal chaplain, and in 1616, dean of Gloucester. Nor was Ellesmere, as chancellor of Oxford, more successful in preventing his elevation in the university, for in 1611 he was elected president of St. John's. On his return from Scotland, which he visited in attendance on the king, he was made a prebendary of Westminster, and in 1621, bishop of St. David's. It was now that he began to give full scope to his favourite views. His Visitation Articles of 1622 were a declaration of war against Puritanism; and enforced the restoration in his diocese of all church decorations and arrangements anciently in use, which had not been expressly abolished by ordinance since the Reformation. Pictures, candelabra, rich altar hangings and painted windows, were again to be seen in the churches of South Wales; the communion table was turned into an altar; and the altar was separated by a screen from the less holy parts of the church. It was evident to the nation that the church was now to be deprotestantized both in doctrine and worship, and that much of the work of King Edward's and Queen Elizabeth's divines was to be undone.

On the accession of Charles I., in March, 1625, it soon became evident that Laud was even a greater favourite with the new monarch than he had been with the old. He was chosen to officiate at the coronation in preference to Bishop Williams of Lincoln, whose puritanical tendencies had brought him into disfavour; and soon after he was promoted to see of Bath and Wells, and made dean of the chapel royal and a member of the privy council. When Archbishop Abbot was suspended from his functions, Laud was one of five bishops intrusted with the administration of the primacy; he became the soul of the commission, and as such virtual primate of the realm. Soon after, in July, 1628, he was elected to the see of London. After the assassination of Buckingham he became more indispensable than ever to the king; and along with Wentworth, earl of Strafford, of whose policy of 'thorough' he fully approved, he became the king's chief instrument in his fatal attempt to set up and establish an absolutism both in church and state. In May, 1633, he accompanied Charles to Scotland, where he would have introduced at once the English liturgy and order if he had not been overruled by the Scottish bishops, who, understanding better than he the feeling of the nation, advised that it would be safer to impose upon Scotland a service-book that might in some sense be called her own than the prayer-book, however excellent, of her 'auld enemies of England.' But his resolute will made itself felt in the composition of this new liturgy; if the book must be less English, it should also be less Protestant: the consecration prayer in the communion service was brought as near as possible to the Roman formula; benedictions for the dead and other suspicious features were also

introduced; and blinded by the infatuation which has so often been the ruin of despotism, Laud and his misguided master never doubted that they should be able either to corrupt or to coerce the conscience of a whole nation, which, since the days of Knox, had never abated one jot in its hatred and abhorrence of 'papisty' and all 'popish dregs.' Soon after his return from Scotland, on the 4th August, 1633, Laud was made archbishop of Canterbury, and on the same day, it is said, he had the offer of a cardinal's hat. He declined to become a prince of the church of Rome; but the form of his declination was mild indeed. 'He felt something in him which said no, so long as Rome was not otherwise than she was.' For some years he continued at the height of ecclesiastical power, and did his utmost to repress the free spirit of Puritanism, exciting against himself an amount of hatred which eventually wrought his ruin. The story of his tragic end, however, is well known to every reader of English history, and need not be here dwelt upon. When the Long Parliament assembled in 1640, it was evident to observers that his life was doomed. On the 1st of March, 1641, he was thrown into the Tower, and there he lay for three years before his cause came to a public hearing. On the 12th of March, 1644, proceedings began in the House of Lords, but it was not till 2nd January, 1645, that sentence was finally given against him. On the 10th of the same month he was beheaded on Tower Hill, and he died with a composure and dignity becoming his character as a Christian bishop. His body was removed in 1663 to St. John's College, Oxford. His dying words, to the effect that only his zeal for the church had brought him to the scaffold, need not be denied. But his zeal for the church had been intemperate and fanatical. It had made him a willing instrument of royal despotism, and a chief agent in trampling upon the rights and liberties of the kingdom. It had narrowed his understanding and poisoned his heart. Wither he was a liberal patron of learning and scholars. He was a great benefactor of the University of Oxford; and the sumptuous buildings which he erected there, the Arabic chair which he founded, and the numerous valuable manuscripts which he presented to the Bodleian library, still remain to attest his enlightened and munificent concern for the interests of education and letters.

LAUDANUM. [OPIMUM.]

LAUDI, or LODI, in music, the Italian name given to certain spiritual or sacred songs, and composed in praise of God, or the Virgin Mary, or even the Saints. They were somewhat different from the common hymns. The name *Laudisti*, or *Laudesi*, was applied to the members of a society instituted at Florence during the fourteenth century for the performance of the *Laudi*. (Dr. Busby.)

LAUENBURG, a duchy of the Germanic Confederation, bounded by Lubeck, Mecklenburg Schwerin, Holstein, and the river Elbe. It extends from lat. 52° 21' to 53° 48' N., and from 10° 13' to 11° 3' E. long. On the eastern border are several lakes, the chief of which are the Ratzburg See, and the Schaal See. The principal rivers are the Stocknitz and the Delvenau. The surface is generally flat, sandy in the centre, and marshy in the south. The duchy is divided into three arrats or districts—Ratzburg, Lauenburg, and Schwarzenburg. The

area is stated to be 404 square miles, and the population, 50,147. The town of *Lauenburg*, the capital, is situated on the right bank of the Elbe, at the mouth of the Delvenane or Stocknitz Canal, 27 miles S.E. of Hamburg. It has a custom-house and a large transit trade. Population of town proper, 1200, with suburbs, 3800. [DENMARK; SCHLESWIG.]

LAUGHARNE. [CAERMARTHENSHIRE.]

LAUGHTER, as physically defined, is an emotion entirely confined to the human species. It is a peculiar agitation of the body, an organical titillation, as it were, which, rising suddenly and irresistibly, affects at once the face and throat, the thorax, and the abdomen. In its most limited sense it is a convulsion of the diaphragm. [DIAPHRAGM.] It is usually a pleasant sensation, but occasionally, as in cases of hysteria, it assumes a painful character, and is no longer under the slightest control of the will. While, however, the corporeal phenomenon is so simple, the nature of the mental state, and of the object by which it is produced, is more complicated and debatable. On this subject a great variety of opinion has prevailed. To determine the common characteristic of all those things termed 'ludicrous' has been found a problem of no common difficulty. According to Aristotle the ridiculous is some error in truth or propriety, but at the same time neither painful nor pernicious. Cicero says that the chief, if not the sole object of laughter, is that which, without impropriety, marks out and exposes an impropriety. Among moderns Hobbes is of opinion that the source of laughter is a sudden glory arising from conception of some eminency in ourselves by comparison with the infirmity of others, or with our own formerly. Beattie and Priestley agree in making the ridiculous to arise out of a misrelation or incongruous union of objects; while Lord Kames considers a contrast to be the essence of the laughable. Perhaps nine cases out of every ten of the really ludicrous are cases of the pleasure of degrading something, and we may presume that the remainder are of the same general character, though the fact is disguised by surrounding circumstances. The ridiculous is not any fixed and constant property of certain objects, but it is purely relative and dependent upon the subjective states and conditions of individual minds. The simpleton and the boor laugh heartily at what scarcely provokes a smile in the educated man and the sage, and on the other hand, much will excite a laugh in the latter which would not move a muscle in the face of the former. Such, again, is the effect of a gay or a gloomy temperament, that a Democritus will laugh where a Heraclitus would weep.

LAUMONITE occurs crystallized and massive. Primary form an oblique rhombic prism. The colour is a reddish white, the lustre vitreous. It is translucent; and when heated at the blow-pipe it gives a white enamel, which, by a continued heat, is converted into a transparent glass. It is a compound of silica, alumina, lime, and water.

LAUNCE (*Ammodytes lancea*), the name of a species of fish related to the eels. It is also known as the Sand-launce, or Riggle, and is found abundantly on the British coasts. It has a great power of digging in the sand, and uses this as a refuge from the attacks of larger fishes. Its usual length is from five to seven inches.

LAUNCESTON. [CORNWALL.]

LAUNCESTON, a town in the colony of Tasmania, the second in importance in the island. It is situated at the northern extremity of the county of Cornwall, and at the head of the navigation of the river Tamar, 35 miles above its estuary at Port-Dalrymple, and 98 miles from Hobart Town. The greater part of the agricultural produce of Tasmania is exported from Launceston, and there is an extensive and increasing trade with Australia, it being the nearest port to that continent. The town was made a free port in 1845. The value of the exports and imports is about 500,000*l.* or 600,000*l.* a year. The population in 1861 was 10,359, but it has since been considerably augmented.

LAUNCH is the sliding or movement of a ship from land into water. The vessel is built upon an inclined slip, having one end deep in the water. A row of blocks of oak are placed on the building slip in the direction of the length of the intended ship, so that their upper surfaces may be in a plane, making an angle of about three degrees with the horizon; and on these blocks is laid the keel. The vessel is supported in equilibrium by an outer framework or cradle, the bottoms of which rests on planed timbers leading to the water, called the ways of the slip. When the vessel is ready to be launched these are greased, and everything which holds the ship in place unfastened, and she glides down into the water stern foremost. The cradle goes with it, but the buoyancy of the water soon separates it from the ship, when it is recovered by boats. It is usual during the process of launching for a lady to break a bottle of wine over the bow, and give the vessel its name. The *Great Eastern* was built with its side parallel to the river, and its launching occupied three months.

LAURA'CEÆ, a natural order of apetalous Exogens, consisting entirely of trees and shrubs inhabiting the warmer parts of the world, and in most cases aromatic; on which account several are mentioned in works on officinal plants. The best known species in Europe is *Laurus nobilis*, the Sweet Bay, a beautiful evergreen, whose fragrant leaves are commonly employed to flavour confectionery. [LAURUS.] Other products of the order are—cinnamon, cassia, sassafras, camphor, and other useful substances.

LAUREATE, POET, from the Latin *laurus*, 'the bay,' an officer in the lord chamberlain's department of the royal household. The earliest mention of a poet laureate in England is in the reign of Edward IV. In the reign of Charles I., 1630, the first patent of this office appears to have been granted, which fixed the salary or pension attached to it at 100*l.* a year, with a tierce of canary wine. The succession of poets laureate since the time of Charles II. has been—John Dryden, Nahum Tate, Nicholas Rowe, Laurence Eusden, Colley Cibber, William Whitehead, Thomas Warton, Henry James Pye, Robert Southey, and W. Wordsworth. Alfred Tennyson is the present holder of that distinction. A commutation of 27*l.* for the allowance of wine is now paid. The title seems to have originated from an old custom of the universities to present a laurel wreath to graduates in rhetoric and versification. The king's laureate was then simply a graduated rhetorician employed in his service. It was formerly the office of the laureate to write an ode on the birth-

day of the sovereign, and on other special occasions. The first has been wisely abolished, but the latter duty is still occasionally performed, the present occupant of the office having written odes on the death of the Prince Consort, the opening of the Great Exhibition of 1862, and the marriage of the Prince of Wales.

LAUREL. [LAURUS.]

LAUREL WATER. The leaves of cherry laurel contain a volatile poisonous oil, and the elements of prussic acid; but a sedative narcotic, of great use in allaying neuralgic pains, spasmodic cough, and palpitation of the heart, is made from them by distilling a mixture of bruised cherry laurel leaves and water, after twenty-four hours maceration. It is important to remark that the use of bay leaves in cooking, to flavour puddings, custards, &c., has led in several instances to serious mistakes. In many cases the leaves of the cherry laurel are used by cooks as recklessly as bay leaves, having acquired the name simply of laurel, instead of *cherry laurel*. Even sculptors have encircled the brows of their marble heroes with the wrong leaf.

LAURENCEKIRK. [KINCARDINE.]

LAURENTIAN SYSTEM. [GEOLOGY.]

LAURINE, an acrid and bitter principle contained in the berries of the laurel. Its smell resembles that of laurel oil. It is insoluble in water. When heated, it melts, and volatilizes without leaving any residue. The berries contain only about one per cent. of this substance.

LAURISTINUS (*Viburnum*), a genus of dicotyledonous plants belonging to the natural order *Caprifoliaceæ*, or honeysuckle family. The common Lauristinus (*Viburnum tinus*), which is to be met with in almost every garden, is a native of the south of Europe. Other species which may be named are the Tree Viburnum (*V. lentago*), the Wayfaring tree (*V. lantana*), and the Guelder rose (*V. opulus*), which are all garden favourites. [VIBURNUM.]

LAURUS, a genus of the natural family of *Lauraceæ*, to which indeed it has given its name. It includes as a species one of the most celebrated trees of antiquity, and until recent times some of the most elegant and useful of the vegetable kingdom. They are now, however, placed in distinct genera. [CASSIA; CINNAMOMUM.]

The Laurel, or Sweet Bay, now alone remains in the genus *Laurus*, and is the *L. nobilis* of Linnæus, a native of the north of Africa and south of Europe and of Asia; at least it has been so long naturalized in these countries that it would be difficult to ascertain whence it was originally introduced. The Bay-tree attains a height of twenty or thirty feet, and is cultivated in gardens, not only on account of its elegant appearance, but also for the aromatic fragrance of its leaves, which are evergreen and quite smooth. The fruit is endowed with aromatic properties as well as the leaves, whence both have long been used in medicine as stimulants and carminatives, as well as a fatty oil expressed from the seed.

LAUSANNE, the capital of the Swiss canton of Vaud, is situated near the northern shore of the Lake of Geneva, on three steep hills, which project from Mont Jorat, and are separated by deep ravines. The situation of Lausanne is picturesque; but the interior of the town is far from pleasing, the streets being

narrow, very steep, and ill paved. The cathedral, a vast Gothic structure of the eleventh century, and the handsomest church in Switzerland, is adorned with a lofty tower, and also a spire 200 feet high. The church of St. François is also a very old building. The castle, formerly the residence of the bishop of Lausanne, is now the council-house of the canton. The other remarkable buildings of Lausanne are—the college, which contains a large library and a museum; the penitentiary; the charity schools; cantonal hospital, lunatic asylum, barracks, and theatre. The educational institutions comprise, besides the cantonal college, military, drawing, and other schools, numerous literary societies, and collections of art and science. The town has 20,516 inhabitants. Manufactures of woollen cloths, paper, leather, watches, and jewellery, are carried on. In the town are several public baths, libraries, an English chapel, &c. The environs present very delightful scenery. Steamers from Geneva and other points on the lake put in daily at the suburb of Guchy, which is built on the shore of the lake. The house inhabited by the historian Gibbon is still shown in Lausanne. Madame de Staël had a residence in the vicinity.

LAUSITZ or LUSATIA, was the name of an old division of Germany, with the title of Margravate, now forming the circle of BAUTZEN, in Saxony, and part of the governments of Potsdam, Frankfort, and Liegnitz, in the kingdom of Prussia. The chief towns are Ebersbach, Kameng, Gross-Schönau, Reichenau, Hernhut, and Zittau, in most of which there are extensive linen manufactories.

LAVA, in Geology, the most general designation of the mineral substances which are erupted in a melted state from volcanic vents. Lava, when observed as near as possible to the point from whence it issues, is for the most part a semifluid mass of the consistence of honey, but sometimes so liquid as to penetrate the fibre of wood. It soon cools externally, and therefore exhibits a rough unequal surface, but the internal mass remains liquid long after the portion exposed to the air has become solidified. The temperature at which it continues fluid is considerable enough to melt silver.

According to Von Buch, almost all lavas are to be viewed as a modification of trachyte consisting essentially of felspar, and united with titaniferous iron; they generally contain glassy felspar, and often inclose augite, leucite, hornblende, mica, olivine, specular iron, and many other minerals, developed by crystallization from the fused mass. Basalt, another of the characteristic volcanic rocks, contains, besides much felspar, a considerable admixture of augite or hornblende, and is rich in oxide of iron, sometimes titaniferous. About one-half of the weight of all lavas is silica: the other half consists of earthy and alkaline ingredients varying greatly in proportions.

The certainty with which the mineral ingredients of lava can be identified depends principally on the degree of crystallization which circumstances have permitted. There is in lava every degree of variation, some specimens being of granitic, others of earthy, compact resinous, or vitreous texture. According to conditions of solidification—in water, in air, or in fissures of the earth—the minerals which occur in lava are variously distributed; and the masses appear

compact, porous, cellular, vesicular, cavernous, spongy, or filamentous.

LAVAL, the capital of the French department of Mayenne, is situated in $48^{\circ} 4' N.$ lat., $0^{\circ} 46' W.$ long., 152 miles W. by S. from Paris, and has 28,142 inhabitants. The principal part of the town stands on the slope of a hill, on the right bank of the Mayenne, and consists of irregularly built, narrow, steep, and crooked streets of dark timber-framed houses, each story of which overhangs the one below it, so that a considerable part of the buildings overhang and darken the dreary streets. From the midst of these dismal buildings, and close to the river, rises the extensive old castle of the lords of La Tremouille, surmounted by a lofty round tower, which formed the keep: this castle is now used as a prison. Near the castle an old bridge thrown across the river leads to a new suburb, regularly built with wide straight streets, on the left bank of the river. Another suburb called Avenières is interesting on account of its elegant church, which dates from 1040. The principal buildings in the old town are—the churches of La Trinité, des Cordeliers, and St. Vénérand; two hospitals, founded about the year 800; the public library; town-hall; theatre; a large and handsome linen market. The town has a tribunal of first instance, a tribunal and chamber of commerce, and a college. It is the centre of a large manufacture of table and household linen and linen yarn, for the sale of which there are weekly markets; calico, flannel, cotton handkerchiefs, serge, soap, leather, &c., are also made; and there is a good business done in flax, wine, brandy, clover seed, timber, iron, marble, &c. Laval is a walled town; it was taken by the English in 1466, but recaptured by the French in the following year; and suffered greatly in the Vendéan war at the end of the last century. In 1793 it was held by the Vendéans, who, in October of that year, under the command of Larochejacquin, defeated with terrible slaughter a large army of republicans near the town. The railway from Paris to Brest passes through Laval.

LAVANDULA SPICA, a native of southern Europe, of which there are two varieties, if not distinct species, termed *L. latifolia* and *L. angustifolia*. The former is also called Spike Lavender, and the oil which it yields differs considerably from the oil of *L. angustifolia*, or *L. vera*, and is termed Oil of Spike or foreign Oil of Lavender. This sort is much less fragrant and of a deeper green colour than the oil of the true lavender, and is merely used in painting, or to adulterate the genuine oil, which is so extensively employed in the preparation of perfumes. The flowers of *L. angustifolia* are the parts employed in medicine.

LAVATER, JOHANN KASPAR, was born November 15, 1741, at Zürich, where his father was a physician. He performed the duties of a preacher in his native town. In 1767 he published his admired 'Swiss Songs,' and in the following year his 'Aussichten in die Ewigkeit' ('Prospects of Eternity'). In 1769 he was made deacon of the Orphan-house church at Zürich. His 'Physiognomic Fragments' appeared in 1775, in 4 vols. 4to. It is said that in after-life Lavater had less faith in physiognomy than at first. He regarded the beginning of the French Revolution with satisfaction; but his opinions changed after the decapitation of the king. When, on September 26, 1799, Massena took Zürich, Lavater, who was busied

in the streets exciting the Swiss soldiery and aiding the sufferers, was shot. He suffered a long time from his wound, and died on the 2nd January, 1801.

LAVATERA (in honour of the two Lavaters), a genus of plants belonging to the natural order *Malvaceæ*. *L. arborea* (Tree Mallow) is a native of Italy, Spain, Portugal, the north of Africa, and the Canary Islands, on maritime rocks; also in Britain, in the Isle of Wight, on Portland Island, in Cornwall, and Devonshire. It is the *Μαλάχρη* of Theophrastus ('Hist. Pl.' i. 5; i. 14).

None of the species of Lavatera are of any importance or value, except as ornamental plants. Many of them are hardy, easily cultivated, and well adapted for shrubberies. The greenhouse and frame species will thrive well in a mixture of loam and peat, or any light soil. They may be planted out during the summer against a south wall, and if protected in the winter by a mat, will generally survive throughout the year. The perennial species grow in any kind of soil, and may be propagated either by dividing the plants at the root, or by seeds. The annual and biennial kinds should be sown in the open border during the spring. The species chiefly worth cultivation in gardens are *L. Olbia, flava, unguiculata, Neapolitana, Cretica, Lusitanica*, and *trimestris*.

LAVAUER. [TARN.]

LAVELANET. [ARIE'GE.]

LA VENDÉE. [VENDÉE.]

LAVENDER, the name of hoary, narrow-leaved, fragrant bushes, inhabiting the south of Europe, the Canaries, Barbary, Egypt, Persia, and the west of India, with generally blue flowers. Twelve species are described, of which two only are of general interest, namely, the common Lavender (*Lavandula vera*) and Spike Lavender *L. spica*, both natives of sterile hills in the south of Europe and Barbary.

LAVEN'DULIN (from *lavender*), a translucent mineral, of a vitreous greasy lustre; specific gravity 2.72; constituents, silica, alumina, lime, potash, and oxide of manganese.

LAVER, a substance sometimes used as food, consists of the fronds of marine plants belonging to the genera *Porphyra* and *Ulva*. Common purple laver is furnished by *Porphyra laciniosa* and *P. vulgaris*, two species common on rocks and stones in the sea on many parts of the British coast. They derive their botanical name from their beautiful purple or violet colour.

LAVOISIER, ANTOINE LAURENT, was born at Paris, August 16, 1743. His father spared no expense in his education. When only twenty-one years of age he obtained the prize offered by the government for the best essay on lighting the streets of Paris. In 1768 he was admitted an associate of the French Academy, and in 1769 obtained the appointment of one of the farmers-general of the revenue. He was afterwards appointed to superintend the numerous saltpetre works of France.

During the Reign of Terror he was accused of having, as a farmer-general, mixed water and noxious ingredients with tobacco: he secreted himself for some days; but hearing that his colleagues were imprisoned, he voluntarily surrendered, and was consigned to the guillotine, May 8, 1794.

In a posthumous and incomplete publication, consisting of two octavo volumes, entitled 'Mémoires

de Chimie,' Lavoisier, alluding to the term commonly employed of the *French theory*, claims it entirely as his own. It overturns the *phlogistic* theory of Stahl, which had assumed that a peculiar principle called phlogiston was the cause of all combustibility and all metallization. The modern theory of combustion is mainly due to Lavoisier. His analysis and recombination of atmospheric air were ably conceived and executed. He was one of the chief means of bringing about the reformed nomenclature of chemistry. But Lavoisier made more claims to originality than he was able to support. Professor Brande has justly said of him that, 'though a great architect in the science, he laboured but little in the quarry; his materials were chiefly shaped to his hand, and his skill was displayed in their arrangement and combination.'

LAVORO, TERRA DI, a province of the kingdom of Italy, now called Caserta, corresponding to the greater part of the ancient CAMPANIA, is bounded by the Mediterranean on the south-east, and having landward the provinces of Naples, Avellino, Campobasso, Chieti, Teramo, and Aquila, the Pontifical States being on the north-west. It is between lat. $40^{\circ} 48'$ and $41^{\circ} 48'$ N., long. 13° to 15° E. The surface in the east is covered with ramifications of the Apennines, but elsewhere are many fertile plains; and this is one of the richest parts of the Italian peninsula, though along the coast are marshy and unhealthy tracts. The chief rivers are the Volturno and the Garigliano: the principal inlet of the sea is the Gulf of Gaeta.

The products of the province comprise wheat, oil, silk, fruit, and wines. The province extends between the lower ridge of the Apennines, the Mediterranean, and the mountains which encircle the Bay of Naples. The area is 2,294 square miles, and the population in 1862 was 653,464. It is divided into five districts:—1. The plain of Nola in the south-east, which looks like an immense grove of tall elms and poplars planted in rows to support the vines which grow at their feet, and which twist around them, and hang in festoons from tree to tree. Between the rows corn and pulse are sown. The soil is a rich sandy loam. 2. West of Nola is the district of Caserta, which includes the central part of Campania, and is watered by the Volturno. The plains of Caserta and Capua near the mountains are tolerably healthy, well cultivated, and extremely productive; but the plain of the Volturno, from Capua to the sea, is very unhealthy: it is chiefly occupied by herds of horned cattle. A range of hills, the *Massicus* of the ancients, here divides the basin of the Volturno from that of the Liris or Garigliano. 3. The district of Gaeta, which includes the lower valley of the Liris and the plain of Fondi. The low lands of the Garigliano are unhealthy and desolate; but where the Formian hills stretch near the coast the country is healthy, fruitful, and well cultivated. The plain of Fondi is very unhealthy, owing to a stagnant lake near that town. 4. The district of Piedimonte, which occupies the valley of the Upper Volturno to beyond Venatro, and as far as the great chain of the Apennines of Abruzzo. This part of the country is healthier. The low lands produce wheat and maize, and the lower slopes of the mountains are planted with the olive, while the higher grounds afford pasture or are covered with chestnut trees. 5. The district of Sora, which

embraces the valley of the Upper Liris. This is in great measure a mountainous district, cold in winter, and partaking of the nature and climate of Abruzzo. These five districts are divided into comuni or parishes. Good organzine and sewing silk are made in Caserta; cotton and woollens at Piedimonte; common woollen cloth at Arpino; and there are extensive tanneries at Santa Maria di Capua.

The capital, Caserta, is 17 miles N.E. of Naples, and 6 miles S.E. of Capua; it had, in 1861, 27,728 inhabitants, and is remarkable for the adjoining palace and gardens, which form one of the most magnificent royal residences in Europe. This palace was built by Charles III. The town has also a cathedral, a theatre, churches, convent, hospital, military school, and barracks. Near Caserta is the royal silk factory of St. Leucio. Caserta Vecchia is a fortified place 3 miles to the north-east, with 1200 inhabitants. Nola, a very old town and a bishop's see, with, in 1861, 12,030 inhabitants, contains sixteen churches, convents, extensive barracks, hospitals, a royal college and seminary, cathedral, &c. The town is situated in a wide and fertile plain, 14 miles E.N.E. of Naples. It was anciently one of the largest cities of *Magna Græcia*, besieged by Hannibal after the battle of Cannæ, and was the place where Augustus and M. Agrippa died. Ancient vases and other antiquities are abundant here, and it is said it was the first place where bells were used in churches. Maddaloni, a pretty town at the foot of the mountains, has a royal college and an aqueduct, to convey water to the cascades in the royal gardens. It is 15 miles N.N.E. of Naples, and in 1861 had 20,257 inhabitants. Capua. [CAPUA.] Santa-Maria-di-Capua has 18,000 inhabitants, and a considerable inland trade. It is 3 miles S.E. of Capua, on the site of the ancient city of that name, has civil and criminal tribunals, and many remarkable ruins. Aversa. [AVERSA.] Piedimonte, a modern town N. of Capua, is well built; the inhabitants amounted, in 1862, to 8538. It stands in a fertile plain at the foot of the Apennines, has a royal palace, and manufactures of coarse woollen cloths, caps, paper, cotton, oil, and wine, called Pellagrello. It has very pure water. Cajazzo, an ancient town, 10 miles N.E. of Capua, has a population of 5712. In its vicinity excellent wine is produced. San-Germano, a town with, in 1861, 11,346 inhabitants, is situated on the road leading to Rome by the valley of the Sacco, a feeder of the Liris. The monastery of Monte-Casino, on a steep hill above San-Germano, is the grandest in Europe. Close by are five springs of mineral water, from which this place was anciently called *Casinum Aquinum*. There is a feudal castle, and a magnificent church, still entire. Sora, higher up the Liris, at the foot of the Apennines, is a bishop's see, and has 12,000 inhabitants. It has a cathedral, remains of a Gothic castle, the citadel, and the walls of ancient Sora. Isola-di-Sora, in an island of the Liris, which forms a fine cascade above it, has 4796 inhabitants, who manufacture paper, iron, linen, wire, and cloth. Arpino. [ARPINO.] Aquino. [AQUINO.] Atina, situated among the mountains, has 3935 inhabitants and many antiquities, a cathedral, and a convent. Sessa, on a hill not far from the high road to Rome, with a population in 1862 of 19,419, is an episcopal city,

17 miles N.W. of Capua. It has many benevolent institutions, a cathedral, and numerous churches and convents, and some remains of antiquity. *Teano*, once the capital of the Sidicini, has 4000 inhabitants, a cathedral, and a seminary. *Gaeta*. [GAETA.] *Fondi*, a bishop's see and a frontier town, near the Papal States, in a fertile but unhealthy plain, has 6555 inhabitants, and some remains of Cyclopean walls. The ancient Via Appia, with its old pavement, forms the principal street of the town. *Fondi* is the reputed robber's nest of the frontier.

In the valley of the Liris is the town of *Pontecorvo*, which, with a small territory, surrounded on all sides by the Terra-di-Lavoro, formerly belonged to the pope, but is now part of the kingdom of Italy. It has a population of 9315 inhabitants, a castle, and a cathedral.

LAW. A law (*lex*) has been defined to be a command or rule of the supreme power in a state addressed to all the members of a given community, who owe obedience to such supreme power. To make it efficient there must be some sanction, or penalty, or punishment, or means of enforcing obedience to it. All the laws of any given country may be comprehended under the term the Law of such country; though the term law, as will be presently explained, comprehends more than all the laws (*leges*), properly so called, of any given country; for it comprehends those rules of Law which are not laws or statutes. The law that exists in any given country is called the Positive Law of that country: it is so called simply as being or existing, as placed or fixed.

The word law is used in various senses. The Law of God is the law that he has given to us in the constitution of our nature, and also the Law which he has revealed through Jesus Christ. God's moral government of the world is discoverable by the exercise of our reason and of our moral faculties, the chief and most pre-eminent of which is conscience. We thus learn that man's nature is adapted to certain courses of action, and not to others; by which we mean that some courses of action are contrary to man's nature, when viewed in all its parts, and as governed by the supremacy of conscience, and that other courses of action are conformable to his nature. We learn that perfect happiness is not attainable by man, and that the greatest degree of happiness, if we look at the whole of mankind and not to single instances, is acquired by doing that which we know that we ought to do, or, as it is expressed, by doing our duty. Our duty comprehends our duty to God and our duty towards one another: our duty to one another implies the existence of society, which we cannot conceive as not existing. Society, therefore, is an ordinance of God, and so are the rules by which society is governed; yet not all rules that may exist, for there are many rules in all societies which are contrary to God's law: but rules or laws are one of the modes of God's government of the world.

These rules, in countries where the Christian religion is known and accepted, are the law of God as revealed to us. They do not form a body of rules adapted to all the wants of society, and were not designed to supersede such rules as man can and does frame by virtue of his intellectual and moral activity developed in a social state. But all rules of human

constitution, by which we mean rules not founded directly on revealed religion, are bad rules if they contradict any principle or rule of the Christian religion, which to those nations which accept it is the supreme law, the sanction of which law in this world is the evil consequences to individuals and societies of their violation of it, and in the next world punishment. In countries where the Christian religion has not been received, or in those ages in which it was not known, the rules of morality have been deduced from those principles of reason and that moral sense which all men possess as part of their nature; and the rules of law, or the systems of law in such countries and in such ages, have always had some degree of conformity to natural religion, or that knowledge of our duties which man may attain to without the aid of revelation: they have been admitted to some degree at least as the test and standard of all positive law.

As society exists and must exist, there is a necessity for law, quite independent of religion or of morality; and the true nature of law is only understood when we have formed a clear conception of the several provinces of law and of morality. The object or end of law is sometimes said to be the promotion of the happiness of a community; but this is not true. Law cannot make people happy. If it be said that its object is not to make happiness, but to assist to that end, this is no more than saying that it does something towards enabling people to be happy, if they know how to avail themselves of its advantages. What is really meant by the ill-chosen expression of the greatest happiness being the end of social institutions is, that it is the object of government and of law to secure to all the members of society those things which are means towards the enjoyment of as much happiness as we are capable of, but which things do not of necessity make us either virtuous or happy. They may have just the contrary effect.

The object of law is to secure individual freedom, which is accomplished by the absolute duties which are imposed upon all. The foundation of liberty or freedom is therefore obedience to positive law. Not that obedience will always secure freedom, for the power which exacts obedience may be tyrannical; but without obedience to one power there can be no freedom in a community. The freedom which it is the object of law to secure—which it does secure in some degree in all countries, though often very imperfectly—is the freedom of living such a life as is conformable to the end of our being; to live according to Nature, as this is explained by Marcus Antoninus, Epictetus, and Butler, or in the words of St. Paul, 'to lead a quiet and peaceable life in all godliness and honesty.'

If the Christian rules of life were followed in all their strictness by all mankind, government and law would still be necessary; which consideration further shows that government and law, not particular forms of government and particular forms of law, but government and law generally, are part of God's means by which he governs the world. Man can acquire nothing except by labour; he thus obtains dominion over external things, which he fashions and forms to use: hence the necessity of rules which shall fix the nature of property and the numerous questions that

may arise concerning it. And if we should suppose that a time may come when men shall seek less than they do now the appropriation of things to their several use, we cannot conceive any state of society in which rules as to Ownership shall not be necessary. Man also interchanges the products of his industry, and makes agreements as to the various transactions of life, which are capable of almost infinite diversity both as to form and substance. Accordingly rules are necessary to regulate such agreements, to settle in some way many things which are matters of indifference in themselves, but not matters of indifference so far as they must be settled some way or other, and to determine disputes whenever disputes may arise, as they may do even between people of strict integrity. Thus the matter for a second set of rules is formed, those that relate to Contracts, and also to Obligations which arise otherwise than by contract. The union of male and female for permanent cohabitation in itself requires no determination by law, for the union is founded simply on consent between persons of competent age to live together for life in such form and manner as religion or the morality of the particular country may prescribe. But still rules of law are required to regulate many things in the relation of husband and wife, mainly with reference to property and contracts; and rules of law are also required to regulate the relations between parent and child with respect to property. The different degrees of consanguinity which are the result of marriage have been established for two purposes, to prevent marriages being contracted within certain degrees of consanguinity, and to regulate the distribution of property in cases of intestacy. When a man dies, his personality ceases, and that property which during his lifetime had a distinct character, by being viewed as attached to the owner's personality, would be left without an owner by his death. But rules of law give the owner a power of disposing of this property, in anticipation of death, by a testament, and in case of intestacy they determine the persons to whom it shall go. These four divisions comprehend what the Romans viewed as belonging to the department of *Privatum Jus*, and it is a department of law which exists by the same necessity that society does. It is not directly concerned about morality in any degree; a man may acquire property for immoral purposes or use it immorally. His conduct in the matter is beyond the province of law, so far as simply concerns the use that he makes of his property. Marriage may not be such a union as accomplishes the end of marriage; but it is still regulated by law so far as the regulation of law is necessary and possible, and no further.

Besides the department of Private Law, there is the department that concerns government and administration, the limits of which it is difficult to define; and accordingly this is the department in which the rules of law most frequently extend beyond their proper limits. Criminal Law belongs to this department; and also, properly considered, all judicial procedure.

The origin of law, like that of society, is unknown. The original law of any state exists in the form of immemorial custom, which has long been recognized by the supreme power, or by those to whom the supreme power has delegated the function of declar-

ing what is law. These customs are not called laws, but Customs, Rules of Law, and the like. But there is in all society a constant growth of law produced by new circumstances and new wants; and this is the matter which society furnishes to the judge, and which within certain limits he may declare to be law as the occasion arises. The judge does not make this law: he accepts it, and declares it to be law. In the case of laws properly so called (*leges*), statutes, or acts of Parliament, the judge has to interpret the law; but he adds nothing, if he does his duty—he merely declares the rule of the law-maker or legislator, as well as he is able to ascertain it.

That part of law which is originally declared in writing by the supreme power, or by any persons to whom this power is delegated, is sometimes called Written Law. An Act of Parliament is an example of this kind of law. That law the original of which is not in writing, though writing may be the evidence of its existence, is called Unwritten Law. Such is Customary Law, or law generated by custom.

Law is sometimes divided into Law and Equity, the nature of the opposition of which is explained under EQUITY.

The department of *Jus Privatum* may be distributed into the Law which relates to Persons and the Law which relates to Things; a division established by the Romans. The Law which relates to Persons views them as holding a certain condition or status, independent of their simple personality, and their capacities, incapacities, and duties, simply as living persons. The law which concerns the relations of husband and wife, parent and child, and some others, merely as such relations, is an instance; and this is the only part of *Jus Privatum* which belongs to the law of persons. The Law of Things of necessity concerns persons, but in relations of a different kind. It views persons, not as holding a certain status or condition, but simply as persons who have certain capacities and rights, are subject to certain incapacities, and owe certain duties, the objects of which are material things, either directly or indirectly. It therefore comprehends the Law of Property, of Obligations, of Testaments, and of Intestacy.

The Law of Persons comprehends not only what has been described as included under *Privatum Jus*, but also every other particular status or condition with which persons may be invested, when not considered simply as persons, but as having peculiar powers or rights and duties. Accordingly, the law of persons, thus viewed, comprehends all those who hold public functions of any description, as judges, sheriffs, and all people employed in administration or government. As opposed to this class of persons called Public, all other classes of persons may be called Private.

Law may be, and is sometimes, divided into Civil and Criminal. In the Roman system *Jus Civile* was the peculiar law of Rome, as opposed to all other law; and sometimes when we speak of the Civil Law we mean the Roman law as received in Europe. In the English system the term Civil Law, as opposed to Criminal, is ill-defined. The distinction, in fact, is only made with reference to procedure, and then only in a limited degree. If a man brings an action to recover a piece of land that belongs to him and is held by another, or if he brings an action to recover

a debt, the proceeding is a civil proceeding; but this is not what is meant by the opposition of civil and criminal. If a man sustains an injury from another, by which he acquires a right of action for damages or compensation, a right solely founded on the wrong, his remedy is a civil proceeding. If the proceeding against the wrong-doer is not for compensation or damages, but merely to bring him to punishment, it is a criminal proceeding. There is also a division of law that may be called Penal in the English system, where the proceeding is of a nature to enforce a penalty, part of which may go to the person who brings the action, and part to the Crown. Criminal proceedings are appropriately enough called Pleas of the Crown in the English system, because the proceedings are in the name of the Crown, though private persons may, as a general rule, prefer a bill of indictment.

That law which is now commonly called International Law, or the Law of Nations, is not properly law. The nature of this so called law is explained in the article INTERNATIONAL LAW.

As to the term CODIFICATION, see LEGISLATION.

LAW, CRIMINAL. The professed object of Criminal Law is the prevention of crimes by the terror of punishment. A crime is such an act or omission as makes the person who is guilty of the act or of the omission liable to a punishment or penalty provided by law. If the act or omission is such that some particular person or persons, who are injured by the act or the omission, can legally obtain compensation from the person who has injured them, the act or omission is called a civil injury. Thus the nature and object of the legal procedure make the distinction between Crime and Civil Injury. Viewed as immoral acts, many civil injuries are worse than many crimes. But such acts or omissions for which the law affords redress only have in England been usually denominated civil injuries as contradistinguished from crimes.

Crimes, according to the English law, are divisible into two great classes, which depend upon the mode of proceeding peculiar to each.

1st. Such as are punishable on indictment or information (the Common Law methods of proceeding).

2ndly. Such as are punishable on summary conviction before a justice or justices of the peace or other authorized persons, without the intervention of a jury (a mode of proceeding derived entirely from special Statutory Enactments).

Offences punishable on Indictment or Information.

Indictable offences are distributable into four classes or divisions: Treasons, Præmunires, Felonies, and Misdemeanors. Persons who commit the offences which constitute the last-mentioned division may also be prosecuted by criminal information instead of being indicted.

The distinction between these classes is, for the most part, a merely arbitrary one; the consequence of which is, that offences in their nature wholly undistinguishable are, in many instances, separated and subjected to punishments widely disproportionate, and to forms of procedure widely dissimilar. In fact, the only real distinguishing feature between one class of crimes and another, at the present day, is to be found in certain peculiarities of punishment and procedure incident to each. Formerly, however, the

classes of crimes were marked by distinctive characteristics; but they have subsequently, either by artificial constructions of the courts or by legislative enactment, been made to embrace offences of a very different nature from those originally included within them. For instance, the crime of treason, whether high or petit, implied a violation of the allegiance due from an inferior to a superior. In the case of high treason, so called 'by way of eminent distinction,' it was the violation of the allegiance due from a subject to his liege lord and sovereign; and in case of petit treason, which was limited to the murder of a husband by his wife, a master by his servant, or an ecclesiastic by his inferior, who owed him faith and obedience, it was the breach of the allegiance of private and domestic faith.*

The characteristic above pointed out can no longer be traced in many of the various constructive treasons which have been created by the courts. It will be sufficient here to give a single illustration of the mode in which the law of treason has been stretched to reach cases totally inconsistent with its original design. By one of the clauses of the Statute of Treasons (25 Edw. III. c. 2) it is declared to be treason to *levy war against the king*. A riotous assembly attempting by force to redress a public grievance, as, for example, to pull down *all* inclosures, or to burn *all* meeting-houses, has been held to be a *levying of war* within the meaning of this clause, although there has been no direct intention or design whatever against either the state or the person of the king. This construction is said to depend upon the *generality* of the design. If the intention be to pull down *particular* inclosures or meeting-houses only, the offence is a mere riot, and in quality a simple misdemeanor. Although the generality of the design may be a reason for awarding a higher punishment in the former than in the latter case, there appears to be no reason for construing an offence, which but for such generality would be a misdemeanor only, to amount to the crime of treason in levying war against the king. The Criminal Law Commissioners (4th, 5th, and 6th Reports) have recommended that this offence should no longer be considered to fall within the Statute of Treasons. They propose that the only assemblings or risings of the people which should amount to a levying of war against the king should be such as are against the person of the king, or against any army or force appointed by him, in opposition to his authority, or with intent to do him bodily harm, or impose any restraint upon his person, or to depose him, or to dispossess or deprive him of any portion of his dominions or regal authority, or with intent by force or constraint to compel him to change his measures or counsels or to put any force or constraint upon or to intimidate or overawe both houses or either house of Parliament; and that no assembling or rising of the people should by reason of any illegality or generality of purpose be deemed to be a levying of war against the king, unless it be with one or other of the several intentions before mentioned. Such riotous and tumultuous meetings as have no such intention in view they recommend should be denominated felonies or misdemeanors

* Petit Treason was abolished by the 9 Geo. IV. c. 31, s. 2, and the offences constituting it declared to be murder only

merely, according to the circumstances by which they are attended.

Again, the term 'Præmunire' was originally applied to offences which consisted in the introduction of any foreign jurisdiction, more especially the authority of the See of Rome, into the kingdom, but has subsequently, to use the language of Mr. Serjeant Hawkins ('Pleas of the Crown,' b. 1, c. 19), 'been applied to other heinous crimes, for the most part having relation to the offences originally coming under the notion of præmunire, but in some instances none at all.' The Habeas Corpus Act (31 Car. II. c. 12) contains an instance of the latter mode of application. By the 12th section of that Act it is made a Præmunire to send any inhabitant of England, Wales, or the town of Berwick-upon-Tweed, a prisoner beyond the seas in defiance of its provisions to the contrary.

The term 'Præmunire' was adopted from the first word of the original writ on which the subsequent proceedings were founded: '*Præmunire* (for *præmoneri*) *facias* A. B. quod sit coram nobis, &c. The Criminal Law Commissioners propose to abolish præmunires as a class of crimes. (7th Report.)

The crime of felony had its origin in very remote times, and was founded upon feudal principles. Its incidents were not formerly, as they are now, of a merely arbitrary nature, annexed to certain criminal acts without reference to any principle. The crime originally consisted in a violation of the feudal contract by the misconduct of the lord or of the tenant, and, where committed by the tenant, occasioned as a consequence the forfeiture of his feud to the lord.

Those crimes, therefore, which induced such forfeiture, and, by a small deflection from the original sense, those which induced the forfeiture of goods also, were denominated felonies; and afterwards by long use the term *felony* came to signify the actual crime itself, and not the penal consequence. 'So that, upon the whole,' to use the words of Blackstone (4 'Com.,' p. 95), 'the only adequate definition of felony seems to be that which is before laid down, viz., an offence which occasions a total forfeiture of either lands or goods, or both, at the common law; and to which capital or other punishment may be superadded according to the degree of guilt.' Where the punishment is less than capital, the offender loses his goods only; where capital, his lands as well as his goods. The crimes which occasioned such forfeiture were originally, with one or two exceptions, capital; but at the present day there are offences for which no greater punishment can be inflicted than imprisonment for a term not exceeding three years, which are felonies, and consequently occasion the forfeiture of all the offender's goods and chattels; whilst other crimes, for which the punishment may be transportation for fourteen years, and in one instance *must* be for life, are misdemeanors only, and work no forfeiture. It is apparent from this that the present law is very defective, and that the amount of punishment is no longer the test of distinction between a felony and misdemeanor.

The term 'Misdemeanor' is used in the English system of Criminal Law to denote such indictable offences as are of a lower degree than felony.

We shall now point out the peculiarities of punishment which distinguish one class of crimes from another at the present day. In order to this, the

penal consequences incident to the whole body of offences constituting each class will be first stated, and then in what respects those consequences differ from each other. The classes will be taken in the same order as above.

1. *Treasons*.—Treasons, with one exception mentioned below, are capital; but whether capital or not, the offender, *upon conviction*, forfeits to the Crown the personal estate of every description, whether in action or possession, or settled by way of trust, which the offender has otherwise than as an executor, or a trustee, or a mortgagee (4 & 5 Will. IV. c. 23, s. 3), at the time of conviction; and in the case of capital treasons, *upon attainder by judgment of death or outlawry*, the blood of the offender is corrupted, but not so as to obstruct descents to such offender's posterity, when they are obliged to derive a title through such offender to a remoter ancestor (3 & 4 Will. IV. c. 106, s. 10); and all the freehold lands and tenements of inheritance in fee-simple or fee-tail, and all other hereditaments (except copyholds), whether in possession, reversion, or remainder; and all the rights of entry on freehold lands and tenements which the offender has, otherwise than as a trustee or mortgagee (4 & 5 Will. IV. c. 28, s. 3), at the time of the offence committed, or at any time afterwards, and also the profits of all freehold lands and tenements which the offender has in his or her own right for life, so long as such interest shall subsist, and if the offender be a male, his wife's dower, are forfeited to the Crown; and all the copyhold estates belonging to the offender at the time of the offence committed are forfeited to the lord of the manor. The above penal consequences are general to all capital treasons, unless, as is sometimes the case, the Act which creates the particular treason expressly exempts from some of them. The before-mentioned non-capital treason renders the party guilty of it liable to those only of the above consequences which accrue upon conviction, since the others follow only upon the party being attainted, that is, sentenced to death or outlawed; which latter, in the case of capital treasons and felonies, is of the same effect as being sentenced to death. The existence of this non-capital treason would appear to be the result of inadvertence. By the Forgery Consolidation Act (11 Geo. IV. & 1 Will. IV. c. 66), it was declared to be treason and punishable with death to forge the great and other royal seals and the sign-manual. By the 2 & 3 Will. IV. c. 123, the punishment of death was repealed for forgery in all but the two cases of wills and powers of attorney to transfer stock (it has been since taken away in these cases also by the 7 Will. IV. & 1 Vict. c. 84); but the *quality* of the offences enumerated in the Forgery Consolidation Act was left without alteration; so that to forge the royal seals, &c., would appear to be still treason, though no longer a capital offence.

The judgment of death in the case of treason is that the offender, if a male, be drawn on a hurdle to the place of execution, and be there hanged by the neck until dead; and that afterwards the head be severed from the body of such offender, and the body be divided into four quarters, to be disposed of as her Majesty shall think fit (54 Geo. III. c. 146); and if a female, that the offender be drawn to the place of execution, and be there hanged by the neck

until dead (30 Geo. III. c. 48, s. 1). The queen, however, may, by warrant under her sign-manual, counter-signed by a principal secretary of state, direct, where the offender is a male, that he shall not be drawn, but taken in such manner as in the warrant shall be expressed to the place of execution, and that he shall not be hanged, but be beheaded, whilst alive, instead. (54 Geo. III. c. 146, s. 2.)

2. *Præmunires*.—The penalties of præmunire, as shortly summed up by Sir Edward Coke (1 Inst., 130 a.), are, 'that from the conviction the defendant shall be out of the king's protection, and his lands and tenements' (i.e., in fee-simple or for life, but not in tail, beyond his life interest therein), 'goods and chattels, forfeited to the king; and that his body shall remain in prison at the king's pleasure, or, as other authorities have it, during life.' These penalties were first imposed by the Stat. 16 Rich. II. c. 5 (commonly called the Statute of Præmunire); and it is by reference to that statute that all subsequent præmunires have been made punishable. It was formerly supposed that a person convicted of præmunire, being put out of the king's protection, might be killed with impunity as being the king's enemy; but by the 5 Eliz. c. 1, ss. 21 and 22, it was enacted that it should not be lawful to kill any person attainted in a præmunire, saving such pains of death or other hurt or punishment as theretofore might, without danger of law, be done upon persons sending or bringing into the realm, &c., any process, &c., from the See of Rome. Præmunires, although they occasion a forfeiture of the offender's lands and goods, are not felonies. To constitute a felony, the offence must have worked a forfeiture at the common law; but in the case of præmunire, the forfeiture is made a part of the punishment by statute merely, which is not sufficient.

3. *Felonies*.—All felonies, as stated above, were originally, with one or two exceptions, punishable with death; but the offender, unless the felony was excluded from the benefit of clergy, was entitled, for a first offence, to be discharged from the capital punishment upon praying that benefit. [BENEFIT OF CLERGY.] But now, since the passing of the 7 & 8 Geo. IV. c. 28, no felony is punishable with death unless it was excluded from the benefit of the clergy before or on the 14th November, 1826, or has been or shall be made punishable with death by some statute passed since that day. Where not capital, felonies are punishable either in the manner prescribed by the statute or statutes specially relating to such felonies, or where no punishment has been or may hereafter be specially provided, with transportation for seven years, or imprisonment for any term not exceeding two years. (7 & 8 Geo. IV. c. 28, ss. 7 and 8.) Such confinement must not, however, be for a longer period than one month at a time, or three months in a year. (7 Will. IV. & 1 Vict. c. 90, s. 5.) In the case of *all* felonies, whether capital or not, the offender immediately *on conviction* forfeits to the Crown all the personal estate of every description, whether in action or possession, or settled by way of trust, which he has otherwise than as an executor, or a trustee or mortgagee (4 & 5 Will. IV. c. 23, s. 3), at the time of conviction, and in the case of all capital felonies, *upon attainer by judgment of death or outlawry*, forfeits to the Crown the profits of all

estates of freehold, and of things not lying in tenure, and to the lord of the manor the profits of all estates of copyhold, which the offender has, otherwise than as a trustee or mortgagee (4 & 5 Will. IV. c. 23, s. 3), at the time of the offence committed, during his life; and his blood is corrupted (but not so as to obstruct descents to the posterity of such offender where they are obliged to derive a title through him to a remote ancestor (3 & 4 Will. IV. c. 106, s. 10), and after his death his copyholds which he holds in fee-simple are forfeited to the lord of the manor. And also, in the case of murder, all his freehold lands and tenements in fee-simple escheat (subject to what is called the crown's year, day and waste) to the lord of the fee. (54 Geo. III. c. 145; Co.-Litt. 391 a.; 4 Black. 'Com.' 385.)

The judgment of death in the case of all capital felonies, except murder, is that the offender be hanged by the neck until dead (2 Hale's 'P.C.' 411); and in the case of murder it is the same, with the addition that the offender's body shall be buried within the precincts of the prison in which he shall have been confined after conviction. (2 & 3 Will. IV. c. 75, s. 16; 4 & 5 Will. IV. c. 26.) The court, however, is empowered, if it shall think that the offender is a fit subject to be recommended to the royal mercy, to abstain from pronouncing judgment of death upon him, and to order such judgment to be entered of record instead; and the judgment so recorded has the same effect as if pronounced and the party were reprieved. (4 Geo. IV. c. 48, ss. 1 and 2; 6 & 7 Will. IV. c. 30, s. 2.)*

A bill introduced into Parliament in the present session (1866) proposes to recognize two degrees of murder: the one including cases of premeditated homicide, which will be punishable by death; and the other, murders committed under provocation, which will not be visited with the capital penalty. Executions are no longer to take place in public.

4. *Misdemeanors*.—The punishment in the case of misdemeanors, where none is specially provided by statute, is generally fine and imprisonment.

It thus appears that the circumstance, so far as punishment is concerned, which distinguishes misdemeanors from all the other classes of offences, is the absence of forfeiture as a necessary consequence of conviction. The distinction between præmunires and felonies (which term, it should be remarked, in its largest sense, includes treasons, on account of the forfeiture which that class of crimes occasions) is, that the forfeiture which ensues upon a conviction of the former is, as before observed, in pursuance of statutable provisions; whereas, in the latter case, it is a common law consequence of the offence, and follows as a matter of course whenever a crime is declared to be a felony. There appears to be no distinction as regards punishment, independently of special statutable enactment, between non-capital felonies (the term is used here in its ordinary restricted sense) and the non-capital treason above described; but the difference between felonies and treasons when punishable with death is very considerable. In the case of

* See *R. v. Hogg*, 2 M. & Ro. 381, where it was held that, since the passing of the 6 & 7 Will. IV., c. 30, death may be recorded in the case of murder as well as other capital felonies, notwithstanding the exception contained in the 4 Geo. IV. c. 48.

felonies the offender upon attainer *forfeits* to the Crown the profits only of such freehold and copyhold lands as he had at the time of committing the offence; during his life, and after his death his copyholds in fee-simple are forfeited to the lord of the manor; and, even where attainted of murder, though his freehold estates in fee-simple fail after his death, it is not as a consequence of the law of forfeiture, but because they escheat for want of heirs capable of succeeding to them, owing to his blood being corrupted by the attainer; and it is on account of such estates escheating and not being forfeited that they go to the lord of the fee (that is, subject to the crown's year, day and waste), and not to the Crown, unless there appears to be no intermediate lord between the offender and the Crown, in which event the Crown takes as ultimate lord of the fee. In the case of treason, however, the offender upon attainer, instead of forfeiting to the Crown the profits merely of such freehold lands as he had at the time of committing the offence, during his life, forfeits all freehold estates of inheritance, as well those in fee-tail as those in fee-simple, and not only such as he had at the time of the commission of the offence, but those also which he may acquire at any time afterwards; and instead of forfeiting to the Crown the profits of his copyholds during his life, and to the lord of the manor his copyholds in fee-simple only, he forfeits at once to the lord of the manor *all* the copyholds belonging to him at the time the offence was committed. Where the offender is a male, his wife's dower is also forfeited to the Crown, which is not the case in felony. It is to be observed that the Crown is now empowered (see 59 Geo. III., c. 94) to restore the whole or any part of any lands or hereditaments to which it becomes entitled by escheat or forfeiture to the family of the offender—a provision which has greatly mitigated the harshness of the law of forfeiture. The Criminal Law Commissioners, however, have recommended the entire abolition of the confiscation of property as a necessary incident to convictions for treason or felony.

According to the law of England, all persons above the age of seven years, except such as by reason of unripeness, weakness, unsoundness, disease, or delusion of mind, are incapable of discerning, at the time they do an act, that the act is contrary either to the law of God or the law of the land, are criminally responsible for such act; but temporary incapacity wilfully incurred by intoxication or other means is no excuse. An infant of the age of seven and under fourteen years, however, is to be presumed to be incapable of committing a crime until the contrary be proved. Duress, also, inducing a well-grounded fear of death or grievous bodily harm, will excuse a person acting under such duress in all cases except treason and murder; and a married woman committing any offence, except those last mentioned, if her husband be present at the time, shall be presumed to have acted under his coercion, and be entitled to an acquittal, unless it appear that she did not so act. A married woman also shall not be liable to conviction for receiving her husband or any other person in his presence and by his authority.

The following provisions are of general application. By the Stat. 7 Will. IV. and 1 Vict. c. 90, s. 5, it is enacted that no court shall direct any offender to be kept in solitary confinement for any longer period

than one month at a time or than three months in the space of one year.

By the Stat. 7 Will. IV. and 1 Vict. c. 85, s. 11, power is given to the jury on the trial of any person for any felony whatever, where the crime charged shall include an assault against the person, to acquit of the felony, and to find a verdict of guilty of assault against the person indicted, if the evidence shall warrant such finding; and thereupon the court may imprison the person so found guilty of an assault for any term not exceeding three years, with or without hard labour or solitary confinement, or with both.

By the Stat. 1 Geo. IV. c. 57, s. 3, it is provided that, where the punishment of whipping on *female* offenders formed, before the passing of that Act, the whole or part of the sentence to be pronounced, the court may pass sentence of confinement to hard labour for any time not exceeding six months nor less than one month, or of solitary confinement, in lieu of the sentence of being whipped. In all cases, therefore, where whipping is mentioned to be part of the punishment, without its being restricted to males, the above provision operates.

By the 3 & 4 Vict. c. 111, made perpetual by 5 & 6 Vict. c. 85, members of joint-stock or other banking companies, consisting of more than six persons, committing offences against or with intent to injure or defraud such co-partnerships, are made liable to the same punishments as if they had not been or were not members of such co-partnerships.

The following treasons are punishable with death:—*

1. Compassing the death of the king (which term includes a queen regnant) or of his queen, or their eldest son and heir; violating the king's companion (*i.e.*, his wife) during the coverture, or the king's eldest daughter unmarried, or the wife of the king's eldest son and heir; levying war against the king in his realm, or being adherent to the king's enemies in his realm, giving them aid and comfort in the realm or elsewhere, and being thereof attainted of open deed; or slaying the chancellor, treasurer, or the king's justices of the one bench or the other; justices in eyre or justices of assize, or any other justices assigned to hear and determine, being in their places doing their offices.† (25 Edw. III. st. 5, c. 2.)

2. Endeavouring to prevent the person next in succession to the crown, according to the Acts of Settlement, from succeeding thereto. (1 Anne, st. 2, c. 17, s. 3.)

3. Affirming, by writing or printing, that any other person has a right to the crown otherwise than according to the Acts of Settlement and the Acts for the union of England and Scotland; or that the Crown, with the authority of Parliament, is unable to limit the descent of the crown. (6 Anne, c. 7, s. 1.)

4. Compassing or intending the death or destruction, or any bodily harm tending to death or destruc-

* To conceal or keep secret any treason committed or intended to be committed is termed misprision of treason, and is punishable with loss of the profits of lands during life, forfeiture of goods, and imprisonment for life. (See 1 & 2 Phil. and Mary, c. 10, s. 8.)

† By the 11 Hen. VII. c. 1, it is enacted that no person who attends upon the king for the time being, in his person, and does him true and faithful service of allegiance, or is in other places by his commandment, in his wars, in this land or without, shall for such deed and true allegiance be convicted or attainted of treason.

tion, maim or wounding, imprisonment or restraint, of the person of the king; or to deprive or depose him from the crown; or to levy war against him within the realm, in order to compel him to change his measures or counsels, or in order to overawe the Parliament; or to move any foreigner to invade any of the British dominions; such compassing or intention being expressed by publishing some printing or writing, or by some overt act or deed. (36 Geo. III. c. 7, s. 1, made perpetual by 57 Geo. III. c. 6.)

5. Being married to or being concerned in procuring the marriage of any issue of her present Majesty whilst such issue are under eighteen (in case the crown shall have descended to any such before that age), without the consent in writing of the regent and the assent of both Houses of Parliament. (3 & 4 Vict. c. 52, s. 4.)

6. Knowing any person to have committed any of the before-mentioned capital treasons, receiving, relieving, comforting, or assisting him, or aiding his escape from custody.

Besides the last-mentioned offence, there also existed till quite recently several other capital treasons relating to the See of Rome; but these were repealed by the 7 & 8 Vict. c. 102.

The following treason (the one already alluded to) is punishable with transportation for life or not less than seven years, or with imprisonment for any term not exceeding four nor less than two years, with or without hard labour or solitary confinement, or with both, viz. :—

1. Forgery of the great seal, her Majesty's privy seal, any private signet of her Majesty, the royal sign-manual, the seals appointed to be used in Scotland, and the great and privy seals of Ireland. (24 & 25 Vict. c. 9, s. 1.)

The following are the offences coming under the denomination of *Præmunires* :—

1. Derogating from the queen's courts. (27 Edw. III. stat. 1, c. 1, s. 1.)

2. Deans and chapters omitting to elect a bishop, and archbishops or bishops to consecrate the person so elected, after receiving the queen's *congé d'élire*. (25 Hen. VIII. c. 20, s. 7; repealed by 1 & 2 Philip and Mary, c. 8, and revived by 1 Eliz. c. 7.)

3. Molesting the possessors of abbey-lands contrary to the provisions of 1 & 2 Philip and Mary, c. 8. (1 & 2 Phil. and Mary, c. 8, s. 40.)

4. Obtaining any stay of proceedings, other than by arrest of judgment or writ of error, in suits for monopolies. (21 Jac. I. c. 3, s. 4.)

5. Procuring any stay of proceedings, other than by the authority of the court, in actions brought against persons for making provision or purveyance for the Crown. (12 Car. II. c. 24, s. 14.)

6. Asserting, maliciously and advisedly, by speaking or writing, that both or either House of Parliament has a legislative authority without the Crown. (13 Car. II. c. 1, s. 3.)

7. Sending any subject of the realm a prisoner beyond the seas in defiance of the Habeas Corpus Act. (31 Car. II. c. 2, s. 12.)

8. Asserting, maliciously and directly, by preaching, teaching, or advised speaking, that any person, other than according to the Acts of Settlement and Union, has any right to the throne of these kingdoms, or that the Queen and Parliament cannot

make laws to limit the descent of the crown. (6 Anne, c. 7, s. 2.)

9. Knowingly and wilfully solemnizing, assisting, or being present at, any marriage forbidden by the Royal Marriage Act. (12 Geo. III. c. 11, s. 3.)

The following felonies are punishable with death, viz. :—

1. Destroying ships of war or her Majesty's arsenals, dockyards, naval, military or victualling stores, or other ammunition of war, &c. (12 Geo. III. c. 24, s. 1.)

2. Murder.

3. Unnatural offences.

4. Attempts to murder by administering poison, or by wounding, or by any other means where bodily injury dangerous to life is caused.

5. Burglary, aggravated by striking an inmate.

6. Robbery, aggravated by wounding the person robbed.

7. Piracy, aggravated by endangering the life of any person on board of the vessel in respect of which the piracy is committed. The above offences are provided for by 24 & 25 Vict. c. 100.

8. Setting fire to a dwelling-house, any person being therein. (24 & 25 Vict. c. 97, s. 2.)

9. Destroying vessels with intent to murder, or whereby human life is endangered. (24 & 25 Vict. c. 100, s. 13.)

10. Exhibiting false lights, &c., with intent to bring ships into danger, or unlawfully doing anything tending to the destruction of ships in distress. (24 & 25 Vict. c. 100, s. 47.)

Besides the above offences, that of wilfully and without lawful excuse having or being possessed of any forged stamp used in pursuance of any Act relating to any duties on gold or silver plate made or wrought in Great Britain, for the purpose of marking or stamping such plate, appears to be still punishable with death.

That offence is contained in 55 Geo. III. c. 185, s. 7, by virtue of which enactment it was formerly also a capital crime to forge or utter the stamps provided for marking any such plate, or to fraudulently remove such stamps from one piece of such plate to another, or privately and secretly to use such stamps with intent to defraud the king. The punishment of death for these last-mentioned offences was repealed, however, by 11 Geo. IV. and 1 Wm. IV. c. 66, s. 1 (as to the forging and uttering), and by 4 & 5 Vict. c. 56, s. 1 (as to the removing and fraudulently using); but by some inadvertence (for it is clear that it can never have been intended) the offence of being possessed, without lawful excuse, of forged stamps for making gold or silver plate (the least criminal of all the acts specified in 55 Geo. III. c. 185, s. 7) was still left capital, but by 24 & 25 Vict. c. 98, s. 48, all forgeries which were capital before the 1 Will. IV. c. 66, and are not otherwise punishable under this Act, shall be punished with penal servitude for life, &c.

The punishments of other felonies are penal servitude and imprisonment.

Placing wood, &c., on a railway, with intent to obstruct or overthrow any engine, obstructing engines or carriages, injuries to electric telegraphs, attempts to injure telegraphs, are punishable by 24 & 25 Vict. c. 97.

The whole Criminal Law of England, as regards indictable crimes and their punishments, has been collected and reduced into one body by the Criminal Law Commissioners (see their Seventh Report), and is thus for the first time rendered accessible to the public at large, and is now, with a few exceptions above referred to, contained in 24 & 25 Vict. caps. 94, 95, 97, 98, 99, and 100. Before this reduction the Criminal Law had to be sought for in an immense mass of statutes, reported decisions, records, ancient and modern, and text-books, and on that account could be known but to the few, and those principally engaged in the practice or administration of the law.

The Criminal Law of Scotland differs in many respects from that of England. There is, for instance, no classification of offences under different heads, as we have explained exists in the criminal procedure of the sister kingdom. But perhaps the most important distinction between the two systems is to be found in the fact, that whereas in England no criminal act is punishable as a crime until it has been pronounced to be so by the Legislature, in Scotland every act which is *malum in se*—offensive to public decency and morality—may, at the instance of the public prosecutor, be brought under the cognizance of the High Court of Justiciary [JUSTICIARY COURT]; that tribunal having within certain limits the power of inflicting an arbitrary punishment—that is, one not inferring a capital sentence—for all new and innumerate offences.

The sources of the criminal law of Scotland are ancient custom, the Roman, Canon, and Jewish laws, and the acts of the Scotch legislature (Hume, Commentaries I. 18, *et seq.*); and it is probably to the varied nature of its historical origin that we owe the great discrepancy that exists between the criminal procedure of this country and that of England.

LAW, JOHN, of Lauriston, was born about the year 1681 at Edinburgh, in which city his father was a goldsmith. In early life he was engaged to arrange the revenue accounts of Scotland. After wasting some years in gaming and dissipation on the Continent, Law went to Paris, where he ingratiated himself with the regent duke of Orleans. By the persuasion of Law the first public bank of circulation was established by the regent in 1716, and its management was intrusted to the projector. This bank obtained the privilege for twenty years of issuing notes, which, however, were to be exchangeable on demand for coin. With the view of inducing the public to purchase the bank shares, the Mississippi Company was formed, with a capital of 100 millions of livres, and allied to the bank. Such numbers crowded forward to make investments in the stock of this Company, that the stock rose in price to 2050 per cent., and 150 millions of livres were added to the capital. In the midst of a vast amount of speculation, and the negotiation of large loans to the government, a royal *arrêt* appeared, which suddenly produced an entire revulsion in the public feeling. Under the pretence of a previous depreciation of the value of the coin, it was by this *arrêt* declared necessary to reduce the nominal value of bank-notes to one-half, and of the shares of the India or Mississippi Company from 9000 to 5000 livres. The consequence was that the bank-notes could no longer be circulated at more than one-tenth

of their nominal value, and though the *arrêt* was speedily revoked, the result was that the bank stopped payment. By these proceedings many thousands of families were suddenly reduced to indigence; and Law was obliged to quit France with the wreck of the fortune he might at one time have realized. He resided for some time in different places in Germany, and ultimately settled at Venice, where he died in 1729.

In 'A Discourse upon Money and Trade,' which he wrote and published in Scotland, Law has left a record of the views which led him to his financial schemes.

LAW-MERCHANT. [LEX MERCATORIA.]

LAW TERMS. [TERM.]

LAWES, HENRY, was a native most probably of Salisbury, of which cathedral his father was a vicar-choral, and was born in the year 1600. In 1625 Lawes was appointed one of the gentlemen of the chapel, and afterwards clerk of the cheque to Charles I. In 1633, in conjunction with Simon Ives, he produced the music to a mask presented at Whitehall by the members of the four Inns of Court. About the same time he composed the music to Milton's 'Comus,' which was performed at Ludlow Castle in 1634. A great many of the effusions of the contemporary poets and persons of rank are to be found set to music by him in his three sets of 'Ayres and Dialogues for One, Two, and Three Voices,' published in 1653, 1655, and 1669.

Lawes continued in the service of Charles till the king's death. At the Restoration he resumed his places in the chapel-royal, and composed the anthem for the coronation of Charles II. He died in 1662, and his remains were deposited in Westminster Abbey.

LAWN, a space of ground covered with grass, kept short by mowing, and generally situated in front of a house or mansion.

Previous to laying down, the ground intended for a lawn should be properly trenched and drained, in order that such trees and shrubs as may afterwards be planted upon it should succeed well. After trenching, the soil should be allowed to subside, and the greatest care should be taken to make the surface perfectly even, otherwise a great expense will be afterwards incurred by the loss of time in mowing, which can neither be so quickly nor so well performed where the surface is uneven.

If turf can be readily procured, a lawn is at once produced; and by such means a more uniform distribution of grass may be obtained than by any other means. The surface of a well-fed meadow, or of an old common, closely cropped by sheep and geese, affords the best kind of turf; and if any tall or coarse grasses should be mixed with it, no inconvenience will arise, for everything of this sort will eventually disappear under close mowing; and such only as are dwarf and suited to the soil will ultimately remain. Where a turf is to be produced by sowing, the seeds of such species as are indigenous to the locality, and possess at the same time the property of being dwarf and fine, are to be preferred; but in the event of this method of forming a lawn being adopted, it is always desirable that a narrow slip of good turf should be carried all round the circumference.

Lawns, when once established, require only to be kept neat by the ordinary routine of rolling, mowing, and sweeping, except keeping the surface perfectly even by filling up small hollows with screened mould early in spring.

LAWRENCE, SIR HENRY MONTGOMERY, K.C.B., an eminent Anglo-Indian officer and official, was born at Mattura in Ceylon in 1806, educated at the diocesan school of Londonderry, and afterwards at the Military College, Addiscombe, and entered in 1821 the service of the East India Company as a cadet in the Bengal artillery. He soon acquired a reputation as a very able and intelligent officer. Serving in the Cabul campaign of 1842 with Sir George Pollock, he was made a major, and afterwards filled two important political posts—first as assistant to the political agent in charge of British relations with Lahore, and then as British resident at the court of Nepal. To his experiences in the former capacity we owe the work, at once amusing and instructive, which he published in 1845, 'Adventures of an Officer in the service of Runjeet Singh.' He played a conspicuous part in the campaigns of the Sutlej, and for his services was made a lieutenant-colonel and a military companion of the Bath. In the interval between the first and second Sikh wars he was resident at Lahore, and agent for the governor-general on the north-western frontier, and for his able discharge of his important duties was made a K.C.B. in 1848. On the annexation of the Punjab in 1849, Sir Henry Lawrence was appointed by Lord Dalhousie president of the board for the reduction and government of the newly acquired territory, one of the members of the board being his younger brother, Sir John Lawrence. Great was the success of his measures, civil and military, for the pacification and settlement of the Punjab. The Sikh army was disbanded, an armed police was established, roads were made, and works of irrigation executed on an extensive scale. In 1854 he became a full colonel and honorary aide-de-camp to the queen. At the outbreak of the Indian mutiny Sir Henry had been ordered by his medical attendants to revisit Europe, and was actually on his way to England, but at the pressing request of the Indian government he gave up his European visit, and proceeded to Lucknow as chief-commissioner in Oude. His measures for guarding against mutiny were very judicious. He did all that prudence and foresight could suggest to prevent an outbreak, while he rapidly fortified and provisioned the position which he had selected to defend. These precautions proved the salvation of the English in Lucknow. The mutiny at Lucknow broke out on the 30th of May. On the 1st of July Sir Henry occupied a room in the Residency, very much exposed to the enemy's fire, but which no entreaties would induce him to leave. On the 2nd he was mortally wounded by a shot. In great suffering he lingered on till the morning of the 4th, when he expired. Of his benevolence and sagacity permanent memorials survive in the Lawrence Asylum, and his published writings.

LAWRENCE, SIR THOMAS, P.R.A., was born at Bristol, May 4, 1769. His father was landlord of the Black Bear Inn at Devizes, and he commenced his career by drawing chalk likenesses of his father's customers. So precocious was his ability, that at the early age of ten he set up as a portrait-painter

in crayons at Oxford, and shortly afterwards took a house at Bath, and at once established a good business. His success was extraordinary, and he became after a few years dissatisfied with crayons, and adopted oil-painting instead; yet he was still only a boy of seventeen. In 1787 he settled in London, and in 1791 had so far distinguished himself as a portrait-painter, that, though still under the legal age of twenty-four years, he was elected an associate of the Academy, and in the following year succeeded Sir Joshua Reynolds as painter to the king. He was now the head of his profession at an age at which other painters have generally been labouring in the toils of studentship. He painted the portrait of George III. and Queen Charlotte which Lord Macartney took with him on his embassy to China in 1792. In 1795 he was elected a royal academician, and from this time his career as a portrait painter was unrivalled, and perhaps unprecedented. Yet for the higher qualities of his art his portraits will not bear comparison with the best works of Sir Joshua Reynolds. He seems to have fascinated people much in the same way that Guido Reni did in his early career. There is a certain indescribable sweetness in the execution of both; and Sir Thomas Lawrence's portraits of women and children are often very beautiful. He was so skilful a flatterer of the ladies that he never failed to give satisfaction. With men he was not so successful; his figures are generally out of drawing, the necks being often twice as long as in nature, though this deformity is somewhat disguised by the style of the costume of the time. He was knighted by the prince-regent in 1815, and at the death of West, in 1820, was unanimously elected to succeed him as president of the Academy. He died in London, January 7, 1830. (Williams, *Life and Correspondence of Sir Thomas Lawrence*, 1831.)

LAWRENCE, ST. [CANADA.]

LAWSONIA, a genus of plants of the natural family *Lytharica*, which, consisting of only one or two species, may be found in most Oriental regions in gardens or in field cultivation. *L. inermis* is said by Oriental travellers to be used by the Asiatic women in dyeing their nails and the tips of their fingers, as well as the soles of their feet, of an orange hue. It is also used by the men for dyeing their beards, the orange colour being afterwards converted to a deep black by the application of indigo. The Arabic name of the plant is *Henna*.

LAY (Anglo-Saxon, *ley*, a song), in poetry and music a little pensive song or air, and generally used in that sense by Chaucer, Spenser, Milton, Waller, Dryden, and other classical English poets. The lay was originally formed on the model of the trochaic verses of the Greek and Latin tragedies; but according to Dr. Busby, there were two kinds of lays; the *greater*, which consisted of twelve couplets of verses in different measures; and the *lesser*, which comprehended sixteen or twenty verses.

LAYBACH. [ILLYRIA.]

LAYERING is an operation by which the propagation of plants is effected by laying down or bending the shoots, so that a portion of them can be covered with earth. A shoot so operated on is called a *layer*, and the plant which furnishes the layer bears the name of *stool*.

The part of the shoot intended to form a layer

should be divested of leaves where it is to be covered with the mould, and a slit should be made on the bent part, or the branch should be twisted half round at the bend so as to disarrange the woody tissue, or the bark should be half or three-quarters *ringed*: the shoot is then fixed down by pegs or hooked sticks, cut down to within an inch or so of the ground, and covered with good mould, which must afterwards be kept tolerably moist. In general, roots are emitted in a few weeks, and by the end of a season young plants are obtained quite fit for transplantation. Some plants, however, require to be left for two years on the stools before they are removed, and there are some which can hardly be made to root at all in this manner.

LAZARETTO (in Italian *Lazzeretto*), is the name given to a building or inclosure which is annexed to seaport towns, chiefly in the Mediterranean, for the purpose of keeping confined therein the crews of ships and passengers arriving from places where a contagious disease is known to prevail. The persons thus confined are said to be in *Quarantine*, from the Italian word *quaranta*, 'forty,' because the period of confinement for those arriving from actually infected places is forty days; after which, if no one has fallen ill, they are set at liberty. The name 'lazzaretto' is derived from Lazarus. [QUARANTINE.]

LAZIAN MOUNTAINS. [ANATOLIA.]

LA'ZULITE, *Lapis Lazuli*, occurs crystalline and massive. Primary form of the crystal a cube, but occurs in imbedded rhombic dodecahedrons. Hardness, 5.5 to 6. Colour, azure and different shades of blue; streak, paler blue. Translucent, opaque. Specific gravity, 2.76 to 2.94.

Massive variety amorphous, sometimes in grains, imbedded. Fuses on charcoal, when pure, into a white glass. It is brought from Persia and China, and is employed in the manufacture of *Ultramarine*. It consists of—phosphoric acid, 41.81; alumina, 35.73; magnesia, 9.34; silica, 2.10: protoxide of iron, 2.64; water, 6.06.

LAZZARONI. [NAPLES.]

LAZZI (Germ. *lassig*, 'lazy'), among our Saxon ancestors, a term applied to the third and last class of the people, who were of a servile condition, and born to labour. They could not leave the soil, or quit their servitude, without the permission of the lord; but were in the position of serfs or slaves. The other two classes of society were the *Edhilingi*, or nobles; and the *Frilingi*, or gentry; the latter word signifying to be born free.

LE or LEH, city of. [LADAKH.]

LEA, River. [ESSEX; HERTFORDSHIRE.]

LEAD is a metal of a bluish gray colour, and of considerable brilliancy when fresh surfaces are formed by cutting. If it has not been cooled too rapidly, it is so soft that, even when in pieces of considerable thickness, it may be easily bent. It soils slightly, and leaves on paper or cloth a mark after friction resembling that of plumbago. Its specific gravity is 11.4. The chemical symbol for lead is Pb, and its equivalent is 103.8. Lead may be reduced to thin laminae; but its tenacity is extremely slight, so that a wire about 1-10th of an inch in diameter breaks with a weight of 30 pounds. It fuses at about 612°, and when slowly cooled crystallizes in octohedrons. It is not

a volatile metal, for in close vessels it may be heated to whiteness without subliming. When exposed to the air, it absorbs oxygen and carbonic acid slowly, and acquires a superficial coating of carbonate of lead. If it be exposed to air and water, it is oxidized and converted into carbonate of lead with considerable rapidity; this carbonate has the appearance of minute shining brilliant scales. Though at common temperatures lead is slowly acted upon by the oxygen of the air, it is readily oxidized when the heat is raised.

ORES OF LEAD.—The ores of lead, strictly speaking, are few in number. Indeed the only one which can be properly considered as a working ore is the Sulphuret, but there are various combinations of lead occurring in nature, which we shall notice briefly.

Native Lead.—This is of very rare occurrence; it is found in small globular masses, imbedded in galena, or sulphuret of lead, and a slaggy substance, accompanied with blende and crystals of quartz. *Protoxide of Lead*, *Native Massicot*, occurs in brittle, dull, opaque, yellowish masses, which melt readily by the blow-pipe. *Deutoxide of Lead*, *Native Red Lead*, *Native Minium*, is a dull red earthy substance, which is reduced to the metallic state by the blow-pipe. *Chloride of Lead*, *Columnia*, *Cotunnite*, occurs in small pearly crystals, which are easily fusible and soluble. *Dichloride of Lead*, *Berzelite*, occurs in crystalline masses, with a fibrous and radiated structure, on earthy black ore of manganese. *Sulphuret of Lead*, *Galena*. This almost universally diffused ore occurs in attached *crystals* and *massive*. Primary form the cube. The crystals are opaque and leaden gray. The massive varieties have a granular structure. By the blow-pipe on charcoal the sulphur is first dissipated, and then metallic lead is obtained. In Cornwall and Scotland the veins of this ore traverse primary rocks. In Derbyshire it occurs in veins or beds in transition rocks. It very commonly contains a portion of silver. *Seleniuret of Lead* occurs in granular masses, opaque, and of a bluish lead colour.

Having described the principal native binary compounds of lead, we proceed to notice those which are composed of an *acid* and *oxide of lead*, remarking that the *protoxide* only combines with acids.

Carbonate of Lead occurs crystallized and massive. Primary form a right rhombic prism; brittle; grayish colour; and translucent. It occurs in most lead-mines, and is sometimes used as an ore of lead. *Sulphate of Lead* occurs in right rhombic prisms, variously tinted, and translucent. *Phosphate of Lead*, *Pyromorphite*, commonly occurs in hexagonal prisms, variously coloured, resinous lustre, and translucent. *Arseniate of Lead*, *Gorlandite*, occurs in hexagonal prismatic crystals, yellowish and translucent. *Chromate of Lead* is a rhombic prismatic crystal, reddish coloured, and translucent. *Molybdate of Lead*, or *Carinithite*, is a prismatic crystal of various colours, translucent, and having a resinous lustre. *Tungstate of Lead* is a prismatic crystal, with a conchoidal fracture, a yellowish colour, a resinous lustre, and translucent. *Vanadate of Lead*, or *Johnstonite*, occurs in rhomboidal crystals, brittle, yellowish, and opaque.

We now proceed to mention some artificial compounds and salts of lead, confining our description to such as are most curious in a scientific point of view, or most useful in the arts.

There are four compounds of *Oxygen and Lead*. *Suboxide of Lead* is a dark gray powder, not soluble in acids, but resolved by them into protoxide and metallic lead. It consists of $Pb^2 O$. *Binoxide of Lead* is an insoluble brown powder. It is decomposed by the action of light, by a strong heat, and also by being converted into protoxide by lead and oxygen. In consists of $Pb O^2$. *Protoxide of Lead*, or *Massicot* ($Pb O$); and *Deutoxide of Lead* or *Minium* ($Pb^3 O^4$), is mentioned among the ores of lead.

Chloride of Lead is a colourless, somewhat crystalline powder, which melts by the application of heat, and assumes on cooling a horny appearance, whence it was formerly called Horn Lead. It is sparingly soluble in water, and consists of $Pb Cl$. *Oxichloride of Lead* is used as a pigment by the name of Patent Yellow; it consists of oxide of lead¹⁰, chlorine¹, and is a yellowish crystalline substance. *Sulphuret of Lead* may be formed by melting a mixture of sulphur and lead filings; in appearance it very much resembles lead, and is composed of $Pb S$. *Iodide of Lead* is a yellow powder, sparingly soluble in boiling water, and separates, on cooling, in brilliant flakes. It consists of $Pb I$. *Carbonate of Lead* is very largely employed as a pigment under the name of *White Lead*, or *Ceruse*, from the Latin name *Cerussa*. Various processes are adopted for its preparation; the oldest (which is still preferred by many manufacturers) is that of exposing sheet lead to the action of the vapour of vinegar, in earthen pots, heated by tanners' spent bark. It is a dense white powder, composed of lead¹, carbonic acid¹. *Nitrate of Lead* is a colourless solution, which by evaporation yields colourless octohedral crystals. They decrepitate when heated moderately, and if strongly heated they are decomposed; they consist of oxide of lead¹, acid¹. *Sulphate of Lead* is a dense white substance, insoluble in water; it consists of oxide of lead¹, acid¹. *Phosphate of Lead* is also a white insoluble powder; but unlike the sulphate, it dissolves readily in dilute nitric acid. *Acetate of Lead*, frequently called Sugar of Lead, is very largely employed for various purposes. It is prepared by dissolving litharge in acetic acid, and evaporating the solution to its crystallizing point. The crystals are generally minute and prismatic; they are colourless, nearly inodorous, and have a sweetish astringent taste. They consist of acetic acid¹, oxide of lead¹, water³. When this salt is boiled in water with an equivalent of oxide of lead, diacetate of lead is formed, which is used in medicine under the name of Goulard's Extract of Lead. *Chromate of Lead* is largely employed as a pigment. It is of a beautiful yellow colour.

Of the alloys of lead, three are of some importance. Alloyed with antimony, lead forms *Type metal*; *Pewter* consists of about 80 parts tin and 20 lead. Equal parts of tin and lead form *Plumber's Solder*.

History, Manufacture, and Trade.—Lead was known to and used by the Greeks and Romans for various purposes. Among others it was employed for pipes to convey water, just as it is now. The lead mines of this island were worked by the Romans. The chief of them were in Cornwall, Devonshire, Somersetshire, Derbyshire, Durham, Lancashire, Cumberland, Westmoreland, Shropshire, Flintshire, Denbighshire, Merionethshire, and Montgomeryshire; in Scotland, in Dumfriesshire, Lanarkshire, Ayrshire,

and Argyleshire. Lead is also found in Ireland, in the counties of Armagh, Wexford, Wicklow, Waterford, Clare, and Down.

The ore of lead, when extracted from the mine, is called *Galena*, and is combined with various earthy matters. The first processes subsequent to its extraction are those of crushing or pounding and washing the ore. The ore is then smelted, sometimes in a common smelting furnace and sometimes in a reverberatory furnace; and the melted metal is allowed to run into a large iron pan, from which it is ladled into cast-iron moulds. It then constitutes what is called Pig Lead. In this state lead always contains more or less of silver. The proportion is sometimes exceedingly minute, varying from 1 to 30 ounces in a ton of lead. The extraction of the silver is always performed when it exists in a proportion sufficient to pay the expense of the process, which varies in different localities according to the cost of fuel. The process of extraction, which is called refining, depends upon the well-known circumstance, that lead, when heated to redness, absorbs a large portion of oxygen from the air, and is converted into an oxide, while silver does not undergo any such change, but retains its metallic form at almost any temperature. Mr. Pattinson, of Newcastle, has introduced an improved process, in which the crystallizing properties of melted lead are brought into requisition.

The most extensive use of lead is in the form of sheets, and pipes, or tubes, for the passage of liquids. To make sheet lead, the pigs are brought to a state of fusion in a large pot or cistern, near to which is placed the table on which the sheet is to be cast. This table, which is usually from 18 to 20 feet long and 6 feet wide, is made either of wood or cast iron. The wooden table has its surface protected by a layer of fine sand, which is wetted and spread evenly and firmly over it before the melted lead is poured on. To prevent the lead from running over the sides, a ledge is provided, two or three inches thick, and two inches high, which forms the margin of the table. An instrument called a strike is also provided to regulate the thickness of the sheet, and to spread the melted metal evenly over the table. In casting the sheet the fused metal is taken from the cistern with an iron ladle, and put into a triangular-shaped iron shovel or peel, placed at the head of the table, which peel being raised so as to pour out the lead upon the table, the strike is brought into use to spread it evenly over the whole surface, the surplus, if any, falling into a vessel placed for its reception at the foot of the table. A sheet of lead weighs 9 cwt., so that its length and breadth will be greater in proportion to the diminution of its thickness. The thickness of sheets of lead is frequently reduced by means of heavy rollers worked by steam power. Rolled sheet-lead is made by the repeated compression between steel rollers of a block of lead several inches in thickness.

Lead pipes are sometimes made, when great exactness of shape is not required, by bending a length of sheet lead of the necessary width over a mandril, and soldering the edges together; but the more usual method of manufacture is by casting and drawing. The casting-box employed is an iron cylinder made in two parts, and put together longitudinally with flanges; inside of this cylinder is placed an iron rod

or core, which is so fixed as to be concentric to the cylinder, without touching it; a space is thus left, into which the melted lead is poured. When this is set, the core is removed, and the cylinder opened, so as to withdraw the pipe, which is much thicker than is needed, and must be lengthened, while its substance is reduced, by drawing it through a succession of holes in steel plates, diminishing gradually in diameter.

In the making of lead shot, the lead is alloyed with a small portion of arsenic, and is melted in a furnace. Close to the furnace is placed a large colander, or perforated plate, into which a portion of the scoria produced in melting the metal is placed, and then the metal is ladled into it. Being somewhat detained by the scoria, it is partially cooled and divided into separate portions, which pass through the colander in the form of globules, which follow in such rapid succession as to have the appearance, to a cursory observer, of a continued stream. These globules fall into a tub of water placed on the lower floor of a lofty tower, or at the bottom of a deep pit. The shot thus formed are of various sizes, and a small proportion are imperfect as regards sphericity. Having been perfectly dried by artificial heat, the shot are sorted according to their sizes by means of a series of sieves, the meshes of which have different degrees of fineness; and the imperfect shot are separated from the perfect by allowing the whole to roll down an inclined plane. The spherical shot are propelled into a receptacle more distant from the inclined plane than those of imperfect form are able to reach. The shot thus sorted are then polished by rolling about half a ton together in an iron barrel which that quantity nearly fills.

The countries to which the largest quantities were sent were France, Australia, India, the West Indies, and Brazil.

The exports of lead from the United Kingdom in 1864 were as follows:—

	Tons.	Value.
Ore, ...	174	£3,015
Pig, ...	27,868	593,366
Rolled and sheet, .	4,103	93,780
Piping and tubing, .	1,610	38,501
Shot, ...	2,186	53,527
Litharge of	5,502	12,784
Red, ...	2,874	67,966
White, ...	3,023	83,918

In the same year, different varieties of lead, imported from foreign countries, were re-exported from Great Britain to the amount of 1241 tons; value, 25,008*l*.

The imports of lead in the same year—chiefly from Italy and Spain—consisted of—

	Tons.	Value.
Ore, ...	3,015	£33,532
Pig and sheet, . .	30,616	611,273
Red, ...	8	167
White, ...	64	1,609
Acetate of	86	2,806
Litharge, ...	509	9,763
Manufactures, . .	50	4,579
	34,348	£663,729

Lead mines have been opened and worked at various parts of the United States, especially at Galena, in Illinois.

Action of Lead on the Human System.—In a

purely metallic state, lead produces no action on the human system except such as arises from its mechanical properties; but as soon as it becomes oxidized, it can combine with the contents of the stomach, and produce different effects, according to the nature of the substances it meets with. 'In whatever form lead is habitually applied to the body, it is apt to bring on the train of peculiar symptoms: the inhalation of its fumes, the habitual contact of any of its compounds with the skin, the prolonged use of them internally as medicines, or externally as ointments and lotions, and the accidental introduction of them for a length of time with the food, may, sooner or later, equally induce *Colica Pictorum*, or Painter's Colic. Of all exposures none is more rapid or certain than breathing the vapours or dust of the preparations of lead.' (Christison.) The action of lead on the human frame differs greatly according to the kind of preparation of lead, the quantity employed, the length of time or frequency of exposure to it, and the channel of its introduction into the body. 'One class of symptoms indicates inflammation of the alimentary canal; another, spasm of its muscles; and a third, injury of the nervous system, sometimes apoplexy, more commonly palsy, and that almost always partial and incomplete. Each of these classes of symptoms may exist independently of the other two; but the last two are more commonly combined.' (Christison.) Fatal cases from poisoning by large quantities of the salts of lead are not numerous, as there is in general time to administer antidotes; but death from the slow and insidious introduction of lead into the system is of frequent occurrence. The principal source of these is the use of water or other fluids containing lead in solution, the intermixture of lead, as adulterations or accidentally, with articles of food, or handling preparations of lead in the daily business of artisans, such as painters, plumbers, &c.

The lid or cover of cisterns should never be made of lead, as the vapour which condenses on it possesses all the solvent power of distilled water. It is also unsafe to use water which has flowed over leaden roofs, more particularly in towns, as the surface of the lead is almost invariably coated with some soluble salt.

No kind of adulteration or impregnation with lead, from accident or ignorance, is more common than that of wine or cyder. Even a single shot of lead left by accident in a bottle after cleaning has produced severe colic; and the more extensive use of the salts of lead to *fine* wines, as it is termed, that is, to remove their acid taste and make them sweet, has occasioned most serious consequences.

In small medicinal doses acetate of lead acts as a sedative and astringent. It manifests its sedative effect even when applied externally, and lessens discharges from ulcers, though its application to these is not always safe. Even white lead (carbonate of lead) ointment applied to ulcers has proved fatal.

LEAD, BLACK. [PLUMBAGO.]

LEAD-LINE. Ships are said to be in *soundings* when the sea-bottom can be reached by a weight lowered from a ship, with a line attached. Lead-lines are carried by every ship or vessel afloat, and are either called *hand-lines* or *deep-sea-lines*. The hand-lead weighs about 7 lbs, and its line varies in length from 20 to 40 fathoms. The lower part of

the lead is scooped out and filled with tallow, to which loose substances at the bottom adhere, and show the nature of the bed of the sea; this alone frequently acquaints a mariner with his ship's position. The deep-sea-lead weighs from 25 to 35 lbs., and is attached to a line of far greater length.

LEAF, an expanded part of a plant attached to the axis, and from whose axils leaf-buds are developed. It is usually thin, and traversed with one or more veins composed of woody and vascular tissue; sometimes it is fleshy, and occasionally cylindrical, or nearly so. The veins are held together by a green or coloured parenchyma, which is inclosed in an epidermis pierced by stomates or openings. A leaf is either united to the stem by means of a petiole or stalk, or it is sessile, that is to say, seated on the branch without an intermediate stalk. Through the petiole pass the veins before they can expand into the broad or green part forming the blade of the leaf.

The petiole is usually articulated with the stem, rarely with the blade of the leaf; the latter, however, sometimes happens, as in the orange. It usually loses itself in the parenchyma of the blade, but sometimes passes beyond it, and in compound leaves often forms a tendril or spine. Sometimes, as in the orange and in the *Nepenthes*, and some other plants, it assumes the appearance of the leaf itself.

When leaves have but one blade, they are simple, as in the apple; but when there is more than one blade, each seated on a ramification of the petiole, a leaf is called compound.

The substance of the leaf consists of parenchyma connecting the vascular tissue. It differs greatly in different plants, and appears to be so arranged as to meet the wants of the species in which it is found. Usually the cells of parenchyma belonging to the upper surface are planted perpendicularly upon the epidermis, while those of the under surface are parallel with it; but this varies very much, and it often happens that the arrangement of the parenchyma is alike on both sides of the leaf. All that appears uniform with respect to this substance is, that it contains grains of chlorophyl in abundance, that it is traversed by air cavities in all directions, and that the latter are universally in communication with the stomates. The usual cause of the under side of leaves being paler than the upper is that the parenchyma is more cavernous on that side than the other.

In their position leaves are usually either alternate or opposite, in pairs upon the stems; in some, however, there are more than two leaves placed on the same plane, which are called verticillate.

The function of leaves is to afford an expanded surface for the evaporation of the fluids of the plant, by which means new sap is constantly introduced into the plant. At one time they were supposed to be organs of respiration, digestion, &c., but these views have been exploded since it has been discovered that each individual cell of a plant is self-existent, and produces its own peculiar secretions. (See Plate.)

LEAF-BUD is an important organ of plants. It consists of leaves in a rudimentary state, resembling scales, arranged one over the other, and usually in a spiral manner, around a cellular conical centre, which has the power of growing upon the application of certain stimuli, namely, light and moisture combined with a variable degree of temperature. It is regarded

by physiologists as a miniature plant, having an analogy with the embryo, and although in its natural condition only forming part of a complicated system of organization in connection with other leaf-buds, yet having an independent power of growth, which it is capable of exercising, if separated from the branch or system to which it belongs. This fact is obvious in the common gardening operation of propagation, for which purpose the buds of plants are cut off and made to form new individuals, as in the process called *budding*, in striking from *eyes* (i.e., leaf-buds), grafting, layering, propagation by cuttings, and the like. None of these operations can succeed except through the independent vitality of the leaf-bud. The leaf-bud is always produced in the axil of a leaf. The manner in which the scales of a bud are packed varies very much; and according to the appearance they present when cut through, they have a variety of names, such as duplicate, imbricate, &c.

LEAF INSECT (*Phyllium*), a genus of insects belonging to the order *Orthoptera* and family *Phasmidae*. In some respects they approach the *Mantidae*. The *Phyllium siccifolium* is a native of India. 'Suppose,' says Dr. Duns, 'the top of a sprout of this year's growth be broken from a bay, the leaves stripped off, two of them taken and laid back to back along the sprout to within about a quarter of an inch from the top, you have then the body and head of *Phyllium*. At the end of the bare sprout, two forked, incipient leaves stand out. These will do for the "horns." The midribs of the leaves lying thus along the sprout give, as they taper towards their points, the aspect of the body; while the uncovered projecting part, with its half-formed buds, represents the head and the eyes. The wings will be represented by an oak-leaf cut up the centre of the midribs. These wings bear the most striking resemblance to this leaf thus cut. The regularity of the larger veins, and the distinctness of the smaller ones, are very marked. Then you have the four legs, like fragments of leaflets, joined to the upper part of the body; while two arms, serving the same purpose as the long tentacula of the butterfly, branch off from the shoulder. These, too, are like fragments of a leaf also; but when they are brought together they form an entire leaf, with its base at the head, and its point projecting. When the animal rests among the leaves, its resemblance to them is so great that only an acute observer is likely to detect it; yea, when it flies it looks far liker a stray leaf torn from a branch than a true insect.'

LEAGUE (*Leuca, Leuga, Leuva, Leuweke*, &c.), an itinerary measure, which in modern English means the 20th part of a degree of latitude, or three geographical miles, each of which is the 60th part of a degree. The league of our sailors may be described and easily remembered as 3·456 statute miles of 1760 yards each. The same marine league is used by the French and other nations: besides which, the French have among their itinerary land measures two distinct leagues (or *lieues*; in some of the provinces *lègues*), the first of 2000 toises, or 2·42 English miles, which is the legal posting measure; the second of 25 to the degree, or 2·77 English miles.

The *Leuca* of the ancient English law-writers is necessary to be determined before the rights given by many charters can be defined; but unfortunately the

length of this measure is enveloped in utter confusion. The modern lawyers, we believe, evade the question by setting it down as a mile: thus the legal minimum distance between two markets, which was certainly seven leucæ, is now called seven miles.

By citations in Ducange, Paucton, &c., it appears that Hesychius distinctly describes the *λεῦγη*, and Jerome, Jornandes, &c., the *leuca* (stated by Camden to be derived from the Celtic *leach*, 'a stone'), as a Gaulish measure; and the original Gallic league was set down by the Romans as a mile and a half of their own measure, which was in all probability a rough estimation, first used in the 'Itinerary' of Antoninus. In that work the distances from place to place in Gaul are frequently given in leagues (always in whole numbers), which are in every instance reduced to Roman miles at the rate of a mile and a half to each league. Hence, taking the Roman foot at 11.62 English inches (which is a mean between the most trustworthy measures) and the pace of 5 feet at 58.1 inches, the Roman mile of 1000 paces is 1614 English yards, and the leuca was therefore 2421 yards, subject to the error of the Roman estimation; or 1.376 modern English miles, with the same reservation.

This leuca in all probability was brought by the Normans into England. It is true that the Saxon charters of Ingulphus describe distances in leucæ; but the genuineness of these charters is now considered more than questionable, and perhaps this very circumstance is a presumption against them. But the leuca soon began to vary in length. Ducange cites an old metrologist who speaks of two leucæ, the one legal of 3000 paces, the other common, and varying much in different countries.

The earlier statutes do not define the itinerary measures, confining themselves entirely to those by which land and goods were bought and sold. And the itinerary measures seem to have been on the increase, perhaps for the following reason:—The jurisdiction of towns, monasteries, &c., was usually defined as extending a leuca or a given number of leucæ in every direction from their precincts, so that it became the interest of these powerful bodies to make the leuca as long as possible. The old French term *ban-lieu*, *banni-leuca*, refers to the space over which jurisdiction was granted.

There is sufficient evidence to show, that whatever the mile of a later date may have been, the leuca was generally two miles, though instances occur in which it is still described as 1500 paces.

Bracton (Henry III.) and Fleta (Edward I.) both assert 6 leagues and half a league and the third part of a half (or $6\frac{2}{3}$ leagues) as being the distance between two markets which do not injure each other: because 20 miles is a reasonable day's journey: now (both of them say) if the *dicta*, or day's work, be divided into three parts, the first is for going to the market, the second for business, and the third for returning. This appears to mean that no market should be established within a third of a day's journey of any one who is already within a third of a day's journey of the established market, so as to give him the option of going to either: that is, the two markets must be at least $\frac{2}{3}$ of 20 miles apart, which being further described as $6\frac{2}{3}$ leagues, shows that the leuca is two miles. This quotation is important, as

establishing the meaning which the old law writers attached to the word.

It may then, we think, be confidently asserted, that the league, which began as a mile and a half (Roman), soon became lengthened, until it remained fixed at two of the miles of the day. It appears also that this length of two miles was a settled league at so early a period that it is the measure of our oldest law writers, and of most of the oldest charters. Our conviction is, that the length of the league or leuca was, in the time of the old law writers, equal to $2\frac{2}{3}$ modern statute miles: the old mile being to the modern statute mile in the proportion of 145 to 100.

LEAGUES are confederacies, or political combinations, and the term was very extensively used in the sixteenth and seventeenth centuries. Among the most famous were those of Cambray, Smalkald, Nurnburg, and the Holy League, formed at Péronne in opposition to the Huguenots.

LEAMINGTON. [WARWICKSHIRE.]

LEAP YEAR, the name given to every fourth year of the Julian calendar, in which one additional day (a twenty-ninth day of February) is reckoned. This correction constitutes the distinction of the Julian calendar: the necessity for the Gregorian correction arises from the years being made a very little too long, one with another, by making them consist of $365\frac{1}{4}$ days each, as is done when a day is added to each fourth year. The Gregorian correction is made by omitting three leap years in four centuries, and it is settled that the common years, which would otherwise be leap years, shall be those which terminate centuries in which the first pair of figures is not divisible by four. Thus the years 1800 and 1900 are not leap years, but 2000 is leap year: 2100, 2200, 2300 are not leap years, but 2400 is leap year.

LEASE. A lease, or letting, is sometimes called a Demise (demissio). He who lets land, whether it be for agricultural purposes, or merely a piece of land with a dwelling-house on it, is called the Lessor, and he to whom land is let is called the Lessee. A lease is not properly a conveyance, though it is sometimes called so; it is merely an interest in land for a certain time, and on certain terms. The fact of a lease for years being called an Estate does not alter the nature of the thing. The reservation of a rent is not essential in a lease; but payment of rent is now the chief condition on which lands are let.

To constitute a lease, it is necessary that the lands must be let for a less time than the period for which the lessor has an interest in the lands. If a man parts with all his interest in the lands or tenements, the conveyance is an assignment, and not a lease. The relation that is created by a lease between the lessor and lessee is usually expressed by the phrase landlord and tenant. The lessor has a reversion in the lands which are demised, that is, after the expiration of the lease the land reverts to him. The lessor, by virtue of this reversion, seignory, or lord's title, has the power of distraining on the land for the rent which is agreed on, and for the services which may be due by the terms of the lease; and fealty is always due to the lessor. [FEALTY.] The ordinary lease is that for a term of years, by which lease a rent, generally payable in money, at stated times, is re-

served to the lessor. These stated times are usually quarterly periods.

The words used in a lease for the purpose of conveying that interest in the lands which constitutes a term of years are, 'demise, grant, and to farm let.' These words are derived from the law-Latin expressions 'demisi, concessi, et ad firmam tradidi.' The word 'firma,' farm, is said to signify originally 'provisions,' and 'to farm let' does not properly signify to let to be farmed, in the modern sense of the term, but to let on the condition of a certain rent being paid in farm, that is, in provisions.

The interest which a man acquires in land by a lease for years is a term of years, or an estate for years. The word lease is used in common language also to signify the estate or interest which the lessee acquires by the lease; but the word lease signifies properly the contract by which the lessee acquires the interest in the lands.

The words 'demise,' &c., above mentioned, are the proper words to constitute a lease for years: but any words are sufficient which clearly show 'the intent of the parties that the one shall divest himself of the possession (of the land), and the other come into it for a determinate time.' When the written contract is not intended to be a lease, but an agreement for a future lease, it is often difficult to determine whether the contract is not so expressed as to make it a lease.

At common law, it was necessary for the lessor to enter on the lands in order to make the lease complete, and no writing was necessary. But the Statute of Frauds (29 Ch. II. c. 3, s. 1) enacted, that all leases, estates, interests of freehold or terms of years, created by livery and seisin only, or by parole, and not put in writing and signed by the parties so making the same, or their agents thereunto, lawfully authorized by writing, shall have the force and effect of leases or estates at will only, except leases not exceeding the term of three years from the making thereof, upon which the rent reserved to the landlord during such term shall amount to two-thirds at the least of the full and improved value of the thing demised. A deed is not necessary to constitute the writing a lease, unless the tenement is an incorporeal hereditament or a reversion or remainder. But leases are generally made by deed, because covenants can be made only by deed.

The word 'lands,' which refer to the subject-matter of a lease, comprehends what is upon the lands, as houses and other buildings, though houses and buildings are generally mentioned specifically in the lease.

The law of leases comprehends a great number of rules, which may be conveniently reduced to the following general heads:—

1. The things which may be subjects of leases.
2. The persons who may grant leases, and their powers to grant.
3. The form of leases, and the legal construction of the agreements contained in them.

The examination of these subjects belongs to treatises on Law. A lease may contain any agreements that are lawful. The agreements or covenants in farming-leases ought to be such that the lease may be most beneficial to the landlord and the tenant, and by consequence to the public generally; but this is not generally the case in England at present.

The chief subjects of leases are dwelling-houses and buildings of all kinds, cultivable lands, and mines. Many persons who have not the complete ownership of houses and lands are enabled to grant leases under particular powers; and there are many statutes under which particular classes of persons are enabled or restrained as to the granting of leases, such as bishops, deans and chapters, and others.

In 1845 an Act was passed (8 & 9 Vict. c. 124) entitled, 'An Act to facilitate the granting of certain Leases.' Its object is to substitute abbreviated forms for those previously in use.

Leases in general require either an ad valorem stamp or the common deed-stamp, without which the instrument cannot be given in evidence. Leases for a term determinable on a life or lives not exceeding three, and the leases of all ecclesiastical corporations, whether aggregate or sole, for any term not exceeding twenty-one years, are exempted from the duty. There is also a stamp-duty on agreements for leases.

By the law of Scotland a lease or tack is a 'contract of location, by which the use of land, or any other immovable subject, is let to the lessee or tacksman in consideration of a determinate yearly rent or duty, to be paid or performed to the lessor or landlord either in money, the fruits of the ground, or services.' (Ersk. Inst., ii., 6, 20.)

Leases were originally grants conferred by the superiors of lands upon deserving vassals; but as land increased in value, the conditions inserted in such grants became more stringent and more numerous, till the tack has at last assumed the form of a mutual contract, in the enjoyment of the subjects of which the lessee is protected by law, so long as he fulfils the prestations for which he has become bound by its terms.

At an early period in Scotch law, the legislature interfered to protect the rights of tenants, by converting what had originally been a precarious and uncertain grant, liable to be terminated at any time at the pleasure of the lessor, or by the lands passing into other hands, into a real and indefeasible right in favour of the lessee, passing to his heirs in the event of his death before the *ish* or term of his tack. This was accomplished by the Act 1449, c. 18, which, 'for the safety and favour of the poor people that labours the ground,' provided 'that they and all others that has taken or shall take lands in time to come frae lords, and has terms and years thereof, suppose the lords sell or assailzie that land or lands, the takers shall remain with their tacks until the issue of their terms, whose hands soever the lands come into.' To give a lease the benefit of this Act it is requisite—

- (1) That the lease be in writing;
- (2) That it set forth definitely the name of the parties to it, and describe the subjects let;
- (3) That it specify the rent, either of money or grain, payable by the tenant;
- (4) That it have a determinate *ish* or term of endurance; and
- (5) That it be followed by possession on the part of the lessee.

By 20 & 21 Vict. c. 26, it is competent to make use of a lease as security in payment of borrowed money, or annuities, or provisions to wives and children; that Act providing that leases for thirty-one

years and upwards may be recorded in the register of sasines, and that such recorded leases may be assigned in favour of creditors, the regulation of the assignation being declared effectual to complete the creditor's right under it. Power is also given to the creditor, in default of payment, to enter into possession of the subjects, uplift the rents, sub-let the lands, or to sell the lease.

Leases may either be in writing or verbal. If constituted verbally, a lease cannot endure for more than a single year. Any writing, however informal, if followed by possession, and containing *in gremio* the requisites of the Act 1449, will be as effectual as a formal written lease, not only against the grantor and his heirs, but also against purchasers and other singular successors.

Leases may be renewed from time to time, not only by special agreement, but by tacit relocation; but tacit relocation is not held to be a renewal of the lease for the original term, but only for the current year. Leases terminate either by the landlord removing the tenant for non-payment of rent, or by the tenant's renunciation of the lease, or by the expiry of the term for which the lands have been let. The rules applicable to these proceedings are too numerous to be detailed here.

LEASEHOLD. [LEASE: TENANT.]

LEAST SQUARES, METHOD OF. This is a method which, since its first introduction, has been shown to be the method of finding the most probable truth, when a number of discordant observations have been made upon a phenomenon. The earliest attempt at anything of the sort was made by Cotes, in a tract entitled 'Estimatio Errorum in Mixta Mathesi,' in which he very distinctly recommends a process which is identical with that of the Method of Least Squares. It is remarkable that Cotes proposes his theorem not merely as a mode of finding a convenient mean (as was done by Legendre and Gauss), but as giving positively the most probable result. He even introduces the hypothesis of observations having different weights (though not with perfect correctness), and comes as near as possible to the assertion afterwards proved by Laplace.

Legendre, in his work on Comets (1806), first distinctly proposed the application of the method to any case, and Gauss afterwards stated that he had been in the habit of using it since 1795. Finally, Laplace, in his 'Theory of Probabilities' (1814), and we believe in a previous paper published in the 'Memoirs of the Academy of Sciences,' showed that this method was in all cases the one which the principles of that theory pointed out as giving the result, which, from the observations, has the greatest weight of probability in its favour. It is impossible to give any account of this method in a form brief enough for the present work.

LEATHER. This substance, which is universally employed throughout the civilized world, is prepared from the skins of animals, chemically changed by the process of tanning. This change is effected by means of a substance residing in several vegetable matters, to which the name of *tannin* has been given. When this tannin, which is soluble in water, is applied to the hides of animals from which the hair, epidermis, and any fleshy or fatty parts adhering to them are removed, and which hides then consist wholly of

gelatin, also soluble in water, these two soluble substances so unite chemically as to form the wholly insoluble substance called leather. Of the ox-hides which are converted into leather, those supplied by bulls are thicker, stronger, and coarser in the grain than those of cows; while the hides of bullocks are intermediate between those of the bull and the cow. Such leather is employed for the soles of boots and shoes; for most parts of harness and saddlery; for leather trunks, buckets, hose for fire-engines, and pump-valves; for the thick belts used in military accoutrements; and for the gloves of cavalry. The thick *buff-leather* formerly used as armour, and which was pistol-proof, and would resist the edge of a sword, was made from the hide of the urus, or wild bull. The skins of *calves*, though thinner than those of cows, are thicker than most other kinds of skin which are converted into leather. They are *tawed* or *alumed* for the use of bookbinders, and are tanned and curried for the upper leather of boots and shoes. *Sheep-skins*, when simply tanned, are employed for inferior bookbinding, for leathering bellows, and for various other purposes for which a cheap leather is required. All the *whit-leather*, as it is termed, which is used for whip-lashes, bags, aprons, &c., is of sheep-skin; as are also the cheaper kinds of *wash-leather*, of which gloves, under-waist-coats, and other articles of dress, are made. Mock or imitation morocco, and most of the other coloured and dyed leathers used for women's and children's shoes, carriage-linings, and the covering of stools, chairs, sofas, writing-tables, &c., are also made of sheep-skin. *Lamb-skins* are mostly dressed white or coloured for gloves; and those of *goats* and *kids* supply the best qualities of light leather, the former being the material of the best morocco, while kid leather affords the finest material for gloves and ladies' shoes. Leather from goat-skins, ornamented and sometimes gilt, was formerly used as a hanging or covering for walls. *Deer* and *antelope* skins, shamoied or dressed in oil, are used chiefly for riding breeches. *Horse-hides*, which, considering their size, are thin, are tanned and curried, and are used by the harness-maker, especially for collars; and occasionally, when pared thin, for the upper leather of ladies' walking shoes. *Dog-skins* are thick and tough, and make excellent leather. *Seal-skins* produce a leather similar but inferior to that supplied by dog-skins; and *hog-skins* afford a thin but dense material, which is used mostly for covering the seats of saddles. *Walrus* and *hippopotamus* hides are tanned in considerable numbers for the use of cutlers and other workers in steel goods; 'buffing-wheels' being made of them, often an inch thick, which are of great importance in giving the polish to metal and horn goods. Belts for driving machinery are also made from them.

The manner in which all these skins are tanned and tawed will be found fully described in the article TANNING. We here notice only the finishing processes.

Currying is the general name given to the various operations of dressing leather after the tanning is completed, by which the requisite smoothness, lustre, colour, and suppleness are imparted. The processes of the currier are various. The first is styled *dipping* the leather. It consists in moistening it with

water, and beating upon a trellis-work of wooden spars, with a mallet or mace. After this beating, by which the stiffness of the hide or skin is destroyed, it is laid over an inclined board, and scraped, cleaned, and pared or shaved down on the flesh side, by the careful application of various two-handled knives; and then thrown again into water, and well scoured by rubbing the grain or hair side with pumice-stone, or with a piece of slaty grit, by which means the *bloom*, a whitish matter which is found upon the surface in tanning, is removed. The leather is then rubbed with the *pommel*, a rectangular piece of hard wood, about twelve inches long and five broad, grooved on the under surface, and fastened to the hand. The currier uses several of these instruments, with grooves of various degrees of fineness, and also, for some purposes, pommels of cork which are not grooved at all. The object of this rubbing is to give grain and pliancy to the leather. The leather is then scraped with tools applied nearly perpendicular to its surface, and worked forcibly with both hands, to reduce such parts as may yet be left too thick to a uniform substance. After this, it is dressed with the *round knife*, a singular instrument which pares off the coarser fleshy parts of the skin. In addition to these operations, the currier uses occasionally polishers of smooth wood or glass for rubbing the surface of the leather; and when the leather is intended for the use of the shoemaker, he applies to it some kind of greasy composition called *dubbing* or *stuffing*.

Japanned leather of different kinds is used in coach-making, harness-making, and for various other purposes. 'Patent leather' is covered with a coat of elastic japan, which gives a surface like polished glass, impermeable to water; and hides prepared in a more perfectly elastic mode of japanning, which will permit folding without cracking the surface, are called 'enamelled leather.' Such leather has the japan annealed, something in the same mode as glass: the hides are laid between blankets, and subjected to the heat of an oven at a temperature of 150° Fahr. during several hours.

In making *Russia leather*, the skins are freed from the hair or fleece by steeping them in an ash-lye, then rinsed, fulled, fermented, and cleaned. They are then soaked for forty-eight hours in a bath composed of water mixed with a paste of rye-flour. The skins, when taken out of the bath, are left in tubs for fifteen days, then washed, and immersed in a boiler containing a hot decoction of willow bark, in which they are handled and pressed for half an hour. This manipulation is repeated twice a day for a week, after which the tanning infusion is renewed, and the process is repeated on the same skins for another week. They are then dried, dyed, and curried.

Shagreen, a peculiar kind of leather, or rather of prepared skin, formerly much used for the covers of watch-cases, mathematical-instrument cases, &c., is produced by soaking, scraping, rubbing, softening, salting, and dyeing. The unevenness of surface is produced in a singular way. The grain side of the skin is strewn with the hard round seeds of the Goose-foot or Alabuta. A felt being laid over these, they are trodden deeply into the soft yielding skin; and when dried, the seeds may be shaken out with-

out violence, leaving the skin in a hard horny state, covered with deep indentations.

Leather-splitting machines, by which even very thin skins may be divided into two thicknesses, each of which is capable of being dressed as a perfect skin, have called forth much ingenuity of contrivance. In one machine of this kind, the skin is drawn between two revolving rollers, and presented, as it emerges from their grasp, to the edge of a long and very sharp knife, which is kept continually moving a little backwards and forwards with great velocity.

Leather trade.—The leather manufacture is one of great importance in this kingdom, giving employment in all its branches to more than 350,000 persons, including tanners, curriers, shoemakers, glove-makers, harness-makers, saddlers, &c. It has been computed that the manufactured articles are worth from three to four times as much as the leather itself, and that the total annual value must be at least 20,000,000*l*.

The imports into the United Kingdom of the principal materials used in tanning processes were as follows in the year 1864:—Bark for tanners' use only, 269,124 cwts., value 100,964*l*.; cutch, 59,000 cwts., value 72,851*l*.; divi-divi, 26,360 cwts., value 16,085*l*.; gambier, 228,520 cwts., value 287,022*l*.; sumac, 245,840 cwts., value 168,592*l*.; and valonia, 453,460 cwts., value 328,570*l*. Some idea of the extent of the British leather manufacture may be gained from a consideration of the above large quantities of materials imported in one year, and used simply in the first process of converting skins into leather.

Besides the ox, cow, sheep, horse, and other hides furnished by the home trade, of which no official accounts are kept, vast numbers are imported from South America, Russia, Germany, Australia, and the Cape of Good Hope, and buffalo hides from India.

In 1864 the total value of all kinds of hides and manufactured leather imported into the United Kingdom was 5,047,495*l*.; and of the same materials in a prepared state exported, 3,599,348*l*.

LEAVEN. [BREAD.]

LEBANON. [SYRIA.]

LEBRUN (or LE BRUN), CHARLES, an eminent French painter, was born at Paris in 1619. His merit obtained him the favour of Louis XIV., who appointed him his principal painter, president of the Academy of Painting and Sculpture, and director of the Gobelins manufactory, conferred on him the order of St. Michael, and frequently visited his studio while he was engaged on the battles of Alexander, the best known and most admired of all his works. Lebrun died at Paris in 1690.

LECCE (*Aletium*), a city of South Italy, the capital of a province, with, in 1861, 21,345 inhabitants, is situated 210 miles E. from Naples, and 9 from the coast of the Adriatic. It is a bishop's see, and one of the best built towns in the kingdom, with wide streets, a handsome market-place, several fine churches, a royal college, a cathedral, a castle, convents, founding hospital, and theatre. Considerable trade is carried on here in the agricultural products of the country, the principal of which are oil, tobacco, wool, cotton, and gum. There are also manufactories of lace, woollen, cotton, silk, thread, and snuff. The town is inclosed by walls, and there is a rail-

way from it to Otranto. The area of the province, which was formerly called Terra d'Otranto, is 3292 square miles, and its population in 1862 was 447,982.

LECHLADE. [GLOUCESTERSHIRE.]

LECTERN, or LETTERN (Latin, *lectorium*), is the name given to the movable reading-desk, from which the Scripture lessons are read in our cathedrals, college-chapels, and many churches. They are made of wood or brass. When of the latter material, the upper part, on which the book is supported, is frequently in the form of an eagle with outstretched wings.

LECTOURE. [GERS.]

LECYTHIDA'CEÆ, an important but small natural order of plants with singular fruits, and very large fleshy flowers, inhabiting the woods of South America. They are regarded by De Candolle as a section of *Myrtaceæ*. *Lecythis ollaria*, a tree growing in the forests of Cumana and Brazil, with a hardy woody fruit as large as a child's head, and opening by a lid like that of a jar or urn. It contains numerous large seeds. *L. Zopucajo*, a large Guiana tree, with large handsome-shaped fruit, containing numerous seeds as large as almonds, and quite as agreeable when fresh. They are sometimes seen in the fruiterers' shops in London.

LEDBURY. [HEREFORDSHIRE.]

LEDGER-LINE, tackle used in fishing for barbel or bream; its peculiarity consists in a leaden bullet being fastened to the line about 20 inches above the hook, so that when cast into the water the lead rests upon the bottom, and the hook end of the line swims loosely about. The rod end of the line is kept as tight as possible without lifting the lead off the bottom, till a fish bites at the bait, when a sudden, strong pull brings it to land.

LEDGER-LINES, in music, those lines which are added above or beneath the five lines composing the stave. They consist of such notes as are too high or too low to be placed upon or within the regular stave. The invention of lines is generally attributed to Guido. When first introduced, the spaces between them were not used.

LEDUM, a genus of plants belonging to the natural order *Ericaceæ*. *L. latifolium* is a small evergreen shrub, with an irregularly branched stem. It is a native of the swamps around Hudson's Bay, Labrador, Greenland, and various parts of the United States. This and the other species of *Ledum* have been used as stomachics.

LEE. [KENT.]

LEE, River. [CORK.]

LEE, MRS. HARRIET, one of the authors of 'Canterbury Tales,' was the daughter of Mr. John Lee, a performer at Covent Garden Theatre. Soon after her father's death she commenced a school at Bath, in conjunction with her elder sister Sophia, which they jointly carried on for many years with considerable success. In the meantime they both devoted themselves to the production of works of fiction and the drama. Sophia was the author of 'Chapter of Accidents,' a comedy which was performed on the Haymarket boards, with tolerable success, in 1780; 'Almeida,' a tragedy, in which Mrs. Siddons personated the heroine, in 1796; 'The Hermit's Tale,' a ballad (1787); and 'The Life of a Lover,' a novel in six volumes (1804). Her sister

Harriet entered on the arena of literature a few years afterwards; and in 1786 produced 'The Error of Innocence,' a novel; and the following year 'The New Peerage,' a comedy. In 1797-1805, appeared the 'Canterbury Tales,' of which Harriet was the principal author; the only contribution being the 'Young Lady's Tale and the Clergyman's,' by her sister. Mrs. Harriet's tale of 'Kreutzner,' it is said, suggested to Lord Byron the tragedy of 'Werner.' The noble writer, in his preface, acknowledges that 'the germ of much he had written was discernible in that popular romance.' She was also the author of 'Clara Lennox,' a novel (1797); and 'The Mysterious Marriage,' a play (1798.) She died at Clifton, in 1851, aged 94.

LEE, NATHANIEL, was born in the latter part of the seventeenth century. He was educated at Westminster, and at Trinity College, Cambridge. He wrote thirteen tragedies, of which two, 'Alexander the Great,' and 'Theodosius,' exhibit considerable dramatic power. A derangement of mind led to Lee's temporary confinement in Bedlam. He died in 1691 or 1692, at the age of about thirty-four.

LEE, REV. DR. SAMUEL, Regius Professor of Hebrew in the University of Cambridge, was born at Longnor, co. Salop, in 1783, where he received the first rudiments of his education. At twelve years of age he was apprenticed to a carpenter and joiner. His father dying at an early age, he experienced the greatest hardships. In a communication made to Mr. Scott, of Shrewsbury, he has narrated the early difficulties with which he had to struggle. He there says that at the age of seventeen he formed the determination to learn the Latin language. Out of a small weekly pittance he contrived to obtain possession of Ruddiman's Latin Grammar, Corderius' 'Colloquia,' and Entick's Latin Dictionary. He was soon enabled to read the Latin Bible, Florus, Caesar's Commentaries, Justin, Sallust, Virgil, Horace's Odes, and Cicero's Orations. He afterwards obtained a Greek Grammar and Testament, Schrevelius' Lexicon, and Huntingford's 'Greek Exercises;' and by plodding industry was enabled to master the more difficult Greek classics. In the same manner he acquired a knowledge of Hebrew, Chaldaic, Syriac, and Arabic. At the age of twenty-five he appears to have renounced the further study of languages, as they appeared, in his then humble situation of life, to be entirely useless. He had entered into a matrimonial engagement, and considered his trade as his only means of support. But a fire breaking out in a house he was repairing, all his tools were burnt, and he was thrown upon the world 'without a friend, a shilling, or even the means of subsistence.' While he was thinking of commencing as a country school-master, but had not the means, the Rev. Archdeacon Corbett, who had heard of his attainments, sent for him, and benevolently promoted his interests in various ways. As Lee himself observes, 'It is to his goodness that I am indebted for the situation I at present fill, and several other very valuable benefits, which he thought proper generously to confer.'

For some years Mr. Lee was master of Bowdler's Foundation School in Shrewsbury; which in 1813 he left, on obtaining an engagement with the Church Missionary Society. In the same year he entered at Queen's College, Cambridge, when he rapidly acquired

a knowledge of mathematics, and in 1817 took his degree of B.A. In 1819 he was elected Arabic Professor of the University of Cambridge, and in 1831, Regius Professor of Hebrew, with the accompanying stall in the Bristol Cathedral. In 1833 the degree of D.D. was conferred upon him. His various publications, connected more especially with biblical and oriental literature, tend to show that his acquirements were profound and extensive, and his reading deep and varied. Among other valuable publications may be mentioned his Syriac Versions of the Old and New Testaments (1816); his Hebrew Grammar (1830); Travels of John Batula, translated from the Arabic (1833); the Book of Job, from the original Hebrew (1837); and a Hebrew, Chaldaic, and English Lexicon (1840). He also edited the Malay Scriptures and the Arabic and Coptic Psalter and Gospels, and translated the Book of Genesis into Persian. He likewise superintended the Hindustani Prayer Book, and Morning and Evening Prayers in Persic; and was the author of several miscellaneous pamphlets, sermons, and contributions to the periodical literature of the day. He died in 1853.

LEECH, JOHN, a popular English artist, born in London on the 29th of August, 1817, was educated at the Charterhouse, where his friend Thackeray was his older schoolfellow. The medical profession was chosen for him, but not being congenial to his tastes, he soon abandoned the lancet for the pencil. In August, 1841, in the *fourth* number of *Punch*, he commenced his connection with that popular periodical, and thenceforth his best works appeared in an unbroken series, up to the issue of the 1217th number, in which his last design was published, after his hand had forgotten its cunning for ever. For twenty-three years the genial task of furnishing a weekly supply of pictorial wit and satire for *Punch* was successfully undertaken by Mr. Leech. Several thousand sketches, as full of grace as of humour, furnished the public with food for laughter and meditation, and their popularity is shown by their success when re-issued in folio volumes, each containing some 500 woodcuts, under the title of 'Pictures of Life and Character,' of which several series have been published. The designs for *Punch's Almanac* for many years were chiefly drawn by Mr. Leech. His first separate publication in his own name was 'The Rising Generation,' a series of twelve drawings on stone, 1840. He also illustrated several of the works of Albert Smith and G. A'Becket, as well as Blaine's 'Encyclopædia of Rural Sports.' The chief objects of his satire were the vagaries of male and female attire, the precocity of the young, the pomp of parents, the pride of domestic servants, and the relations existing between the rich and poor. He was equally skilful in depicting feminine beauty and the ragged urchins of the street. As an English gentleman he was kind, manly, and hospitable, and had a large circle of friends. He died on October 29th, 1864, and was buried in Kensal Green Cemetery.

LEECHES (Zoology), *Hirudinidae*, a family of annulose or red-blooded worms, placed by Cuvier in the third order of the *Annelida*, and in the second family of the *Abranches sans Soies*. The classification of MM. Audouin and Milne-Edwards does not differ materially from that of Cuvier.

The ancients appear to have only known the most

common species of leech. Aristotle makes no mention of them, and they do not appear to have been used in medicine in the time of Hippocrates. Pliny describes them very clearly under the names of *Hirudines* and *Sanguisuga*, and the Sea-leech is distinctly mentioned by Belon, Rondelet, and all the writers on natural history since the revival of letters.

The true leeches are all destitute of branchiæ, but there exists a series of small membranous sacs, each of which communicates externally by a minute orifice situated on the ventral aspect of the body. Hence water penetrates into the sacs, and is brought into contact with a mesh of fine vessels ramifying upon them. But though the true leeches are destitute of branchiæ, a sort of worm, usually classed with them from its similarity, is furnished with branchiæ. It is a parasite on the Torpedo, in the Mediterranean and other seas. It is the *Branchelion* of Savigny; *Branchiobdella* of De Blainville; and *Polydora* of Oken.

The true leeches are divided into three sections.

In section 1 the anterior sucker is separated from the body by a distinct strangulation or neck. Genera:—1, *Albione* (Sav.), *Pontobdella* (Leach); 2, *Hæmocharis* (Sav.), *Ichthyobdella* (Blain.).

In section 2 the anterior sucker is very slightly separated from the body. Genera:—1, *Geobdella* (Blain.), *Trochetia* (Dutrochet); 2, *Pseudobdella* (Blain.); 3, *Hæmopsis* (Sav.), *Hypobdella* (Blain.) (the Horse-leech is an example of this genus); 4, *Sanguisuga* (Sav.), *Jatrobdella* (Blain.) (this genus contains the true medicinal Leeches, of which there are several species); 5, *Bdella* (Sav.), from the Nile; 6, *Nephelis* (Sav.), *Erypbdella* (Blain.).

In section 3 the anterior sucker is wanting. Genera:—1, *Clepsina* (Sav.), *Glossopora* (Johnson), *Glossobdella* (Blain.). The two first genera named are parasitic, and attach themselves to fishes. Of many species earth-worms are the favourite prey. (For interesting notices of land leeches, see Sir Emerson Tennent's recent work on Ceylon.)

The imports of leeches into the United Kingdom in 1864 were valued at 9028*l.*, of which amount 7074*l.* came from France, and 1934*l.* from Hamburg.

LEECHES, MEDICAL USE OF. Of the species described in the preceding article it is intended to treat here only of those of the genus *Sanguisuga* (Savigny), as they only can be employed for medical purposes. The *S. medicinalis* is now rare in England, owing to the draining of so many of the ponds and bogs in which it formerly abounded. England derives the very large number required mostly from Sweden, Poland, and Hungary.

The *S. officinalis* has a green body or light blackish green, the back marked with six longitudinal bands of an iron colour, spotted with black spots at their middle portion and edge. The belly is of a yellowish green *without spots*, but broadly bordered with black. The segments of the body are very smooth. It is large, often seven inches long. It lives in pools and rivers. There are three varieties.

S. medicinalis has the body of a deep green, its back marked with six longitudinal bands of an iron colour, pretty clear, spotted with black points, generally triangular. The belly is greenish *spotted*, and broadly bordered with black, and the segments of the

body rough from granular eminences. It inhabits ponds and small lakes.

Leeches are oviparous. The ova remain in the uterus for some time, where they become invested first with a serous membrane, and then with a glutinous fluid, which remains attached to them after their expulsion, and serves as a protecting covering after they are deposited in the clay and holes of the sides of the ponds. The leeches generally deposit the *cocoons* from May to the end of September.

About five years are required before the leech attains a state of maturity; while very young they are quite unfit for medical purposes. They are caught in various ways, by the hand, or by a person wading in the shallow waters during the spring of the year, when they adhere to his naked legs; but in summer, as they have retired to deeper waters, a raft is constructed of twigs and rushes, by which a few are entangled. Baits are deposited, generally pieces of decayed animal matter or liver, to which the leeches resort, and are then caught; but this last method is thought to injure the health of the animal. Many sicken and die on the journey, especially during warm weather. They are conveyed either in bags or small barrels with a canvas cover.

A leech may be known to be in good health if it be active in the water and plump when taken out. Leeches vary in the quantity of blood they can abstract, from one drachm to half an ounce: from one to two drachms is the average. The quantity is often doubled by the expedients resorted to after the leech has been removed, either dry or wet cloths being applied, or in many cases cupping glasses; but cataplasms of linseed meal are most beneficial where they can be applied.

One gray or German leech is deemed equivalent to two green or Hungarian leeches. In applying leeches it should be borne in mind that certain states of the patient hinder or indispose them to bite. Where the skin is very thick, they cannot puncture it, or if the person has been using sulphur, the exhalation of the sulphuretted hydrogen is disagreeable to them; even the fumes of tobacco, vinegar, &c., will prevent them biting; also, if grease, salt, or vinegar, be on the spot to which they are applied, they refuse to attach themselves to it. The existence of hairs on the spot seems to hinder them from biting, and also from forming a vacuum to suck up the fluid, on which account they should be carefully shaved off. The leeches should be taken out of the water, and allowed to creep for some time over a dry warm cloth: various applications are recommended to induce the leech to bite on a particular spot, such as milk, porter, &c.

When the leech has dropped off, it should be seized by the tail and stripped between the finger and thumb, so as to cause it to disgorge most of the blood. It is proper to allow it to retain about a third. This is preferable to applying salt or vinegar to the mouth. It should then be placed in many successive fresh waters, and it may perhaps survive, and after some months be again fit for use.

Should there be any difficulty in stopping the flow of blood when the leech is removed, a weak solution of creasote applied to the part will generally effect it, or felt scraped from a hat, or gum in powder, or flour, or the dust of the puff-ball, or the application

of a compress and bandage, tying a ligature, or touching the wounds with lunar caustic. The patient should at the same time drink a saturated solution of alum, or take dilute sulphuric acid.

The increasing scarcity of leeches renders their preservation and propagation objects of primary importance. The death of a vast number of leeches is occasioned by errors in the method of keeping them. Though aquatic animals, it is not enough that they be supplied with water. They breathe by their entire surface, and are accustomed to change their skin every four or five days. Their body is covered, like that of all animals and plants which inhabit the water, by a slimy or mucilaginous fluid. When present in a limited degree, this mucous secretion is highly serviceable to them; in excess it is destructive. It is impossible for them to diminish it when it has accumulated, or to denude themselves entirely of their old skin, in water only. They must have some resisting body to creep over or through in order to accomplish this object, such as charcoal, sand, pebbles, or moss. The great extent to which the trade in leeches is carried on renders attention to this subject of paramount importance.

LEEDS, a municipal and parliamentary borough, is the principal emporium of the woollen manufactures in the West Riding of Yorkshire. The municipal borough is divided into twelve wards, and is governed by sixteen aldermen and forty-eight councillors. The parliamentary borough returns two members to the House of Commons, the number of electors in 1864 being 7616. The boundaries of the old parish, and the parliamentary and municipal boroughs are the same, being more than seven miles in length and breadth. The population at the last census was 207,165; in 1851 it was 172,270. The town is 22 miles S.W. of York, 189 N.N.W. of London by road, or 192½ by the Great Northern Railway. It is the first in importance in Yorkshire, and the fifth in England.

Leeds is situated on the slope and partly on the summit of a hill which rises from the north bank of the Aire, and from the top declines to the east, west, and north. The northern and southern parts are connected by five bridges, of which one was built before 1376; two others are suspension bridges on the peculiar bow-and-string principle—first introduced by Mr. Leather, of Leeds. Leeds is admirably situated for trade, being placed on the edge of an extensive coal-field, and in the heart of the inland navigation of the county. It communicates with the eastern seas by means of the Aire and Calder Navigation to the Humber, and westward by the Leeds and Liverpool Canal with the Mersey. It is the centre of a system of railways, radiating to all parts of the country.

Cloth is the staple manufacture, but stuffs, steam engines, linen, iron, pottery, thread, silk, carpets, glass, nails, &c., are also manufactured; and there are some coal mines. Most of the cloth is made at home by the hand-loom weavers, and then brought in the rough uncoloured state to the market, to be sold to the finishers. The total number of occupations to which the manufacture gives rise, beginning with pickers, sorters, and washers, and ending with warehousemen and packers, has been estimated at 120. The weavers reside on small dairy farms,

within a distance of ten or eleven miles of Leeds, and usually combine trade with farming. The dye-houses and dressing-shops at Leeds are very extensive. In these establishments both the woollen and worsted goods are finished. The mills at Leeds for the spinning of flax for canvas, linen, sacking, thread, &c., are very extensive; one of the flax mills consists of a single story and a single room, but this extends over nearly two acres of ground, and includes five times as much space as Westminster Hall. There are also large manufactories of glass, leather, earthenware, steam-engines, locomotives, and all kinds of machinery. Indeed, during the last few years the working of iron in Leeds has taken such a stride, as almost to vie in importance with the woollen manufacture; and this circumstance, combined with the fact that so many and such varied works are in full and vigorous operation, has secured for this town a healthy and prosperous progress among the recent vicissitudes and depressions of some of her trades. The manufactures of the town and district are facilitated by the abundant supply of coal produced from the mines in the vicinity of the town.

The principal buildings are St. Peter's church, which will seat nearly 4000 persons, and is a very noble edifice; St. John's, St. George's, St. Saviour's, built in 1843, in the pointed style, with a tall spire; and fourteen other churches in the township, out of more than forty contained in the parish. There are about thirty-five chapels, including two large Wesleyan, Unitarian, in the pointed style, and three Roman Catholic, one with a tower 150 feet high. The new town-hall, a handsome Corinthian pile, 250 feet by 200, with a dome 250 feet high, opened by the Queen in 1858, and in the vestibule of which stands a statue, in white marble, of her Majesty. It includes a hall 161 feet long, with one of the finest and best organs in Europe, and statues of the late Edward Baines, Esq., M.P., and Robert Hall, Esq., M.P. The commercial buildings comprise an exchange, news rooms, and district bankruptcy court, near which is a statue of the late Sir Robert Peel (1852); coloured cloth hall, 383 feet by 198, inclosing 1780 freehold stands; white cloth hall, 297 feet by 210, with 1200 stands; corn exchange, and statue of Queen Anne; stock exchange (1847); a handsome branch of the Bank of England, and seven other banks. There are three theatres, cavalry barracks, with a parade ground occupying eleven or twelve acres; large jail, court-house, Kirkgate covered and open markets, Smithfield cattle market, central market, built at a cost of 35,000*l.* in 1825-27; south or leather market, public baths, museum, school of medicine of high repute, fine arts' society, mechanics' institute, Dr. Priestley's and other libraries, general infirmary (1767), hospital for women and children, and fever hospital, both elegant and imposing buildings; eye and ear infirmary, and general dispensary. The free grammar-school was founded in 1552, and rebuilt in 1860 in the Gothic style, at a cost of 15,000*l.* The town also contains Harrison's, St. John's, and many other schools; Harrison's, Potter's, and Jenkinson's almshouses; Burmantofts industrial schools, in the Elizabethan style, 276 feet long; new workhouse, a magnificent and extensive building in the Elizabethan style, with room for about 800 inmates; and mendicity institu-

tion. A site for a new infirmary was lately purchased, and the first stone of a new building, from designs by George Gilbert Scott, Esq., R.A., was laid on March 29, 1864. The building alone was to cost 64,750*l.*; but with the expense of the site and palisades, streets and boundary walls, the total cost is computed to be not less than 106,000*l.* The borough jail, completed in 1847 at a cost of 40,000*l.*, in the castellated style, is second to none of its class in the kingdom. Besides the Roman Catholic churches, there is also a magnificent cathedral belonging to them, which is available for use, though for want of funds the details have not been all carried out. The grammar-school, which is a branch of a munificent charity left by Mr. Harrison, has a revenue of 1675*l.* a year; it is situated on the edge of Woodhouse Moor, an open piece of ground of above 60 acres in extent, belonging to the corporation; the scholars from this school have a preference in the election to four scholarships at Magdalen College, Cambridge, and to an exhibition in Queen's College, Oxford. The Harrison almshouses, as well as those of St. John's church, which is a very rich foundation, were established and endowed by the liberality of Mr. John Harrison. The infirmary has an annual income of nearly 5000*l.* The charitable endowments are estimated to produce in all nearly 7000*l.* a year. Four exhibitions of 50*l.* each per annum, tenable for four years, are given to those boys who, having attended the Leeds Grammar-School for four years, are proceeding to Cambridge, Oxford, or Durham.

The chief institutions at Leeds for supplementary education, are the Leeds Philosophical and Literary Society, the Literary Institution, the Mechanics' Institute, and the Working Men's Institute. The Philosophical Society's Hall is a handsome building, of the Doric order, and has a spacious lecture theatre and fine museum. The Literary Institution has a large reading room and extensive library. The Mechanics' Institute has a library of 12,000 volumes, reading room and lecture hall, day schools and evening classes, and about 1500 members. In connection with it is one of the most successful schools of art in the kingdom, giving instruction in drawing to 3000 persons. The Working Men's Institute has about 2000 members. There are several libraries—that established by Dr. Priestley being one of the best in the north of England.

Formerly Leeds had an uninviting appearance, and the older streets, Kirkgate, Briggate, and some others, are still narrow and inconvenient; but the modern thoroughfares are good and spacious. The district on the west is new, and inhabited by the wealthier classes. The population on this side is increasing very rapidly, and new streets and roads are being set out by most of the owners of property in this locality.

The October quarter sessions for the Riding, as well as the borough quarter sessions, have long been held at Leeds, and in 1864 it was made an assize town. It is the seat of a district court of bankruptcy, and of a county court. It is also a warehousing town under the Inland Bonding Act of 1860—the revenue derived from articles subject to customs' duty in 1865 having been 38,470*l.*

Leeds was first incorporated in 1626, though it

was only created a parliamentary borough in 1832. The number of voters in 1866 was 7217.

Kirkstall Abbey, about three miles from Leeds, was founded by Henry de Lacie, for the Cistercian order of monks, in 1150. It is a fine ruin, remarkable for its simple grandeur and unity of design. Adel Church, about four miles distant, is an interesting building, erected in 1140. Near it was a Roman station.

In connection with the Leeds waterworks is the store reservoir at Eccup (about six miles north of the town), covering 50 acres, and containing 257,000,000 of gallons. There are also service reservoirs at Westwood and Woodhouse Moor, of 10 and 6 acres, holding respectively 28,000,000 and 5,000,000 of gallons.

There are botanical gardens and cemeteries at Woodhouse Moor, Burmantofts, and Hunslet.

(Communication from Leeds; Thom's *British Directory*; White's *A Month in Yorkshire*.)

LEEK. [ALLIUM.]

LEEK. [STAFFORDSHIRE.]

LEER, or LIER, a well-built market town, in the Hanoverian province of East Friesland, is situated in 53° 18' N. lat., 7° 25' E. long., on the river Leda, which falls into the Ems about three-quarters of a mile below the town. It has several churches, a synagogue, an orphan asylum, two hospitals, and 8225 inhabitants, who manufacture linen, woollen stockings, soap, vinegar, tobacco, and iron wares. It has also an extensive shipping trade, and a considerable business in butter, cheese, and other articles. Ships of 150 tons' burthen come up to the town.

LEET is the district subject to the jurisdiction of a court-leet. Sometimes the term is used to denote the court itself, the full style of which is 'Court-Leet and view of Frank-pledge.' The court-leet is also called a law-day, as being the ordinary tribunal.

One of the least improbable derivations of the word 'leet' is that which deduces lath and leet from the Anglo-Saxon 'lathian,' or 'gelathian,' to assemble, both lath and leet indicating a district within which the free male resiants (residents) assembled at stated times for preparation for military defence, and for purposes of police and criminal jurisdiction. Of the first of these objects scarcely any trace exists in the modern leet. The title of the court as a 'view of Frank-pledge' points to its former importance, under the system of police introduced or perfected by King Alfred, which required that all freemen above twelve years of age should be received into a decenna, dizain, decennary, or tithing, sometimes called a visne, or neighbourhood—in Yorkshire and other parts of the north, ten-men-tale (a number, tale, or *tally* of ten men)—and forming a society of not less than ten friborgs, or freeborrows, freemen, each of whom was to be *borhoe*, that is, pledge or security for the good conduct of the others.

Leets are either public or private. The Public Leet is an assembly held in each of the larger divisions of the county, called a hundred, at which all freemen who are resiants within the hundred are bound to attend in person or by their representatives. These representatives were the reeves or chiefs of their respective tithings, whether designated by that or by any of the other appellations, each of whom was accompanied by four good and lawful men of,

and elected by, the tithing which deputed them. This public court, which was originally called the folk-mote, being held successively in each hundred in the course of a circuit performed by the sheriff, acquired the name of the sheriff's *tourn*; by which name, though itself a court-leet, it is now distinguished from inferior private leets. The private court-leets appear to have been created by grants from the Crown, obtained by the owners of extensive domains (which afterwards became manors), and most frequently by religious houses, for the purpose of relieving their tenants and those who resided upon their lands from the obligation of attending the tourn or leet of the hundred, by providing a domestic tribunal, before which the resiants might take the oath of allegiance, and the frank-pledges might be inspected, without the trouble of attending the tourn, and to which, as an apparently necessary consequence, the criminal jurisdiction of the precinct or district was immediately transferred. In these private leets the grantee, called the lord of the leet, performed the duties which, in the public leet or tourn, after the ealdorman or earl had permanently absented himself, fell upon the sheriff. These duties he might perform either personally or by his steward. As a compensation for this, and his trouble in obtaining the franchise, it appears to have been the practice of the great landowner, who by his money and his influence had procured the grant of a private leet, to claim from resiants a certain small annual payment by the name of certum letæ. In many cities and boroughs the ancient authority of the court-leet was in later times superseded by charter of incorporation, in some of which the popular election of magistrates was preserved entire; whilst in the great majority of cases, the right, though continued in name, was fettered, if not rendered altogether nugatory, by restrictions of various characters and degrees. In other respects, the course prescribed by these charters was adapted to the changes which had taken place in the habits of the people since the institution of the court-leet. Many of the functions of the magistrates in the new incorporations were borrowed from the then comparatively recent institution of Justices of the Peace.

The court-leet is a court of record, which has jurisdiction of such crimes as subject the offenders to punishment at common law. As criminal jurisdiction belongs exclusively to the kingly office, all criminal prosecutions are called pleas of the crown, and the court in which such pleas are held are the king's courts, although granted to a subject. The authority so exercised under the king's grant is called a lordship, and the grantee is said to be the lord of the leet. It may be claimed either by a modern grant or by prescription, that is, long established user, from which an ancient grant is presumed.

Private Leets are commonly held, as public leets must be, twice in the year: within a month after Easter, and within a month after Michaelmas; and even the former cannot, unless warranted by ancient usage, be held at any other time except by adjournment. The court appears to have been formerly held in the open air. It should be held at its accustomed place, though if sufficient notice be given, it may be held anywhere within the district. All persons above the age of twelve years and under

sixty (except peers and clergymen, who are exempted by statute, and women and aliens), resident within the precinct for a year and a day, whether masters or servants, owe suit to (*i.e.*, personal attendance at) this court, and here they ought to take the oath of allegiance.

It was the province of the court-leet, as well the public leet of the hundred as the private leet, to repress all offences against the public peace, and to enforce the removal of all public nuisances. The leet jury may make by-laws. The leet jury elect their chief magistrates, the reeve or constable, &c., of the private leet, and, as it would seem, the high constable (sometimes called the alderman) of the hundred.

Before the Norman conquest, and probably for some time after, this court of the leet was, if not the sole, at least the ordinary tribunal for the administration of criminal justice in the kingdom.

The steward of a leet is a judge of record, and may take recognizances of the peace; and he may impose a fine for a contempt or other offence committed in court, as where a party obstructs the jury in the execution of their duties, or by public officers in the discharge of their duties out of court. For the fine so imposed the lord may distrain or bring an action of debt.

Of common right the constable is to be chosen by the jury in the leet; and if the party chosen be present, he ought to take the oath in the leet; if absent, before justices of the peace. If he refuse to accept the office, or to be sworn, the steward may fine him. If the party chosen be absent and refuses, the jury may present his refusal at the next court, and then he is amerced.

Though the leet has long ceased to be the principal and ordinary court of criminal jurisdiction, its power has been enlarged by several statutes, which give it cognizance over offences newly created, and it does not appear to have been at any time directly abridged by legislative interference. The business of the court has chiefly been affected by the creation of concurrent jurisdictions, particularly that of justices of the peace, who have cognizance of the same matters, as well as of many others over which the court-leet has no jurisdiction.

It is now usual to give fifteen days' notice of holding a court.

The functions of the steward of a court-leet are mostly judicial. Ministerial acts are performed by an inferior officer called the bedel or bailiff, who of common right is appointed by the lord or steward, though by custom he may be chosen by the jury. The steward issues a precept under his seal, addressed to the bailiff of the leet, commanding him to warn the residents to appear at the time and place appointed for holding the court, and to summon a jury. When the court is opened, he delivers to the steward a list of persons summoned as jurymen, together with the suit or resistant roll. The suit-roll is then called over, and those residents who are absent are marked to be amerced. The bailiff then gives notice, 'If any man will be essoigned, come in, and you shall be heard.' The steward, having called for the essoigns (*excuses*), enters them.

The jury is chosen from the body of the suitors, and consists of not less than twelve, nor more than

twenty-three. A foreman is then named, who is sworn as follows:—'You shall well and truly inquire, and true presentment make, of all such articles, matters, and things as shall be given you in charge; the king's counsel, your companions', and your own, you shall keep secret and undisclosed. You shall present no man for envy, hatred, or malice; nor spare any man for fear, favour, or affection, or any hope of reward; but according to the best of your knowledge, and the information you shall receive, you shall present the truth and nothing but the truth.' As soon as the foreman is sworn, and the rest of the jury, they receive a charge from the steward, pointing out the nature of their duties, and of the matters which ought to be presented. The jury make their presentments to the steward, who, in cases of treason or felony, must return the presentments (in these cases called indictments) to the justices of gaol-delivery, if the offenders be in custody; if they be at large, the indictments must be removed into the King's Bench by certiorari, in order that process may issue thereon. In all other cases the steward of the leet has power, upon the complaint of any party grieved by the presentment, or, on the other hand, upon any suspicion entertained as to the concealment of any offence, by non-presentment, to cause an immediate inquiry into the truth of the matter by another jury, though in the former case the more usual course now is by certiorari or traverse.

The ordinary profits of a court-leet are the fines, amercements, and essoign-pence, and belong, in the case of a public leet or tourn, to the king; in the case of a private leet, to the grantee or lord of the leet.

Though the court-leet may now be considered as an antiquated institution in many respects, it is characterized by many valuable features, and in some districts is still efficient.

LEEWARDEN, the chief town of the Dutch province of Friesland, situated in 53° 12' N. lat., 5° 47' E. long., has about 25,000 inhabitants. It is surrounded with an earthen rampart and a wide moat; the broad straight streets are intersected by canals, the banks of which, as well as the ramparts, are planted with trees, and afford very pleasant promenades. The town, which is well built, has manufactures of linen and paper, printing establishments, and a considerable trade, which is much facilitated by numerous canals. The principal buildings are—the town-hall, the ancient palace of the princes of Orange, a synagogue, and twelve churches, the largest and handsomest of which contains monuments of the princes of the house of Orange. There are also an arsenal, exchange, house of correction, and a branch of the Society of Public Good. Leeuwarden is on the river Ee, and on the great canal between Harlingen and Gröningen.

LEEWARD ISLANDS, or *Greater Antilles*, a name given to the West Indian Islands N. of 18° N. lat., and comprising CUBA, Isla-de-Pinos, HAYTI, Puerto-Rico, and JAMAICA, and the smaller isles of Grand Cayman and the Virgin Islands. They extend from long. 64° 15' to 85° W. South of this group are the Windward Islands, or Lesser Antilles.

LEFEBVRE, FRANCOIS JOSEPH, Duke of Danzig, and Marshal of France, was born of humble parents at Ruffach, in Upper Alsace, October 25, 1755. Having lost his father, he enlisted, when

eighteen years of age, as a private soldier in the regiment of French guards. After the Revolution he obtained rapid promotion, and as a captain of his regiment was enabled to render some valuable assistance to the unfortunate family of Louis XVI. While serving with the army of the Moselle during the whole of the campaign in Germany and the Netherlands, and afterwards with the army of Italy, he repeatedly distinguished himself. On the 25th of March, 1799, was fought the memorable battle of Stockach, in which, with only 8000 men, he resisted for many hours the attack of 30,000 Austrians.

When Bonaparte placed himself at the head of affairs, Lefebvre cordially co-operated with him. He was also instrumental in extricating Lucien Bonaparte from his dangerous position in the stormy meeting of the Council of Five Hundred at St. Cloud. These important services were rewarded by the command of the seventeenth military division, the head-quarters of which were at Paris.

In the year 1804 he was raised to the dignity of a marshal of the Empire. He accompanied Napoleon the following year in the Austrian campaign, and in 1806 took an active part at the battle of Jena. In 1807 he was sent with an army of 16,000 men to invest Danzig. He was rewarded for the brilliant success of his expedition with the title of Duke of Danzig.

In the year 1808 Lefebvre joined the Peninsular expedition. In the German campaign of 1809 he rendered himself conspicuous at the battles of Eckmühl and Wagram, and in the dangerous warfare among the passes of the Tyrol. He was also with Napoleon in the disastrous expedition to Russia, and had the command of the old guard. During the retreat he showed considerable military skill. In the campaigns of 1813 and 1814 he adhered to the declining fortunes of his master. It is, however, stated that Lefebvre greatly influenced the abdication of Napoleon, and at the first restoration of Louis XVIII. he was created Chevalier of St. Louis and a peer of France. But on the return of his former chief from Elba, he accepted a seat in his Chamber of Peers. At the second restoration of the Bourbons he was excluded from the Chamber, but recalled in 1819, having been reinstated in his rank of marshal. He died at Paris on the 14th of September, 1820.

LEFKOSIA. [CYPRUS.]

LEG. [SKELETON.]

LEGACY (*Legátum*), a bequest or gift of goods and chattels by will or testament. The person to whom it is given is termed the legatee (*legatarius*).

The bequest is not complete without the assent of the executor or administrator to the will annexed, as the case may be. [EXECUTOR.] But, before such assent, the bequest is transmissible to the personal representatives of the legatee, and will pass by his will. The executor or administrator is not bound to admit that there is anything due to the legatee till the debts of the deceased are paid.

Legacies are of two kinds, general and specific. A legacy is general when it is so given as not to amount to a bequest of a particular thing, or a particular fund of the testator; a specific legacy is a bequest of a specified thing, or a specific part of the testator's estate. There is also a third description of legacy, partaking somewhat of the nature of both kinds

already mentioned, as a gift of so much money, with reference to a particular fund for payment. This is called a *demonstrative* legacy, but it so far differs from one properly specific, that if the fund pointed out fails on any account, the legatee will be paid out of the general assets.

Legacies may be given either absolutely (*purè*, as the Roman jurists termed it), or upon condition (*sub conditione*), that is, on the happening of any contingency, provided it must happen, if at all, within the duration of a life or lives in being at the time of the decease of the testator and twenty-one years afterwards, allowing in addition the period of gestation where the contingency depends upon the birth of a child. When a legatee has obtained such an interest in the legacy as to be fully entitled to the property in it, the legacy is said to be *vested*, and this property may be acquired before the right to the possession of the legacy accrues. A vested legacy is transmissible to the personal representatives of the party entitled to it, or passes by a will; a legacy which is contingent or not vested is no property at all with respect to the legatee. This distinction of legacies vested and not vested seems derived from the Roman law, which expresses the fact of vesting by the words '*dies legati cedit*.'

Formerly, in all cases when a legatee died before the testator, the legacy lapsed or failed, and went to the person appointed residuary legatee by the testator, or if there was none such, to the next of kin, and lapse might also take place (as in the case of a legacy given to a legatee at a particular time, or upon condition, or the happening of a contingency) if the legatee died before the appointed time arrived, or if the condition was not performed, or the contingency did not happen. The Statute 1 Vict. c. 26, s. 33, has modified the old rule.

The English rules by which gifts of legacies are construed are derived from the Roman law, as appears from Swinburn's '*Treatise on Wills*;' and they have been extended and modified by decisions.

It may be stated, as a general rule, that legacies are payable twelve months after the death of a testator, and with interest from that time at 4 per cent., unless the testator has made some special provision as to the time of payment and interest. When a specific legacy consists of some determinate chattel, whether real, as a lease for years, or personal, as a particular horse, the legatee, after assent by the executor to the legacy, may take possession of it, or sue for it by action at law; but where the specific legacy consists of money, &c., and in all cases of general and of demonstrative legacies, no action at law lies unless the executor has, for some new consideration beneficial to himself, expressly promised payment. As a general rule, therefore, it may be stated that the remedies by legatees against executors are afforded by the courts of equity. (Roper '*On Legacies*;' Williams '*On Executors and Administrators*.')

On the subject of legacies (*legata*) under the Roman law, Gaius (ii. 192-255) and the '*Digest*,' lib. xxx., xxxi., xxxii., '*De Legatis et Fidei Commissis*,' are the chief authorities. By the more ancient law there were four forms of legacies, giving to the legatee, according to the nature of the expression employed, either a real right to the thing bequeathed, or a right of action against the testator's heir. During the reign

of Augustus legacies were frequently bestowed in the form of *fidei commissa*, or trusts, which, being merely a request to the testator's heir to deliver over the subject to the legatee, could be constituted not only by a formal and probative testament, which the stricter forms of legacies always required, but also by any informal writing (*codicilli*) under the testator's hand. All these distinctions were abolished by Justinian.

Legacies pay a tax, which is generally to be paid by the executor or administrator, and the stamp which denotes the payment of a legacy is to be affixed to a receipt which is given to the executor or administrator by the person who receives the legacy. They are subject to the following duties:—Children of the deceased, or any lineal ancestor, pay 1*l*. per cent.; brothers and sisters, 3*l*. per cent.; uncles and aunts, 5*l*. per cent.; brothers and sisters of a grandfather and grandmother, 6*l*. per cent.; strangers in blood, 10*l*. per cent. There are also stamp duties on probates of wills and on letters of administration.

By the law of Scotland legacies may be constituted either verbally (*nuncupative*) or by writing. But no verbal legacy can be effectual to any larger extent than 100*l*. Scots (8*l*. 6*s*. 8*d*. sterling). If in writing, legacies may be bequeathed either by the will itself or by codicil. Legacies are payable out of the free movable estate of the deceased, after payment of all his debts; but if the funds of the testator are insufficient to meet these, the legacy will fail, no legacy being effectual against creditors. Legacies may be either *general*, of a certain portion of the deceased's effects, in which case the legatee has merely a personal right of action against the executor; or *special*, when a specific subject, or debt, or sum of money, is bequeathed, in which case a *real* right to that subject or fund is constituted in the legatee. Legacies are also *universal*, when the subject bequeathed is the testator's whole movable estate; or *residuary*, when it comprehends what of that estate remains after paying expenses, debts, and other legacies. Legacies may be left not only to one or several persons, but, in the event of their failure, to a series of individuals, specially named or described. The rights of parties under legacies with such substitutions have given rise to many intricate questions of vesting. All legacies of 20*l*. and upwards out of estates above 100*l*. are subject to legacy duty.

LEGATE (from the Latin *legatus*, which is a participle from *lego*, and signifies one who is sent with a certain commission). This word had various significations among the Romans. The legates (*legati*) were the chief assistants of the proconsuls and propraetors in the administration of the provinces. The word *legatus* also signifies a military officer who was next in rank to the general or commander-in-chief in any expedition or undertaking, and in his absence had the chief command. The word *legatus* is also often used to denote a person sent by the Roman state or sovereign power on matters that concern the public interest.

At the present day a legate signifies an ambassador, or nuncio, of the pope.

There are several kinds of papal legates: *legatus a latere*, *legatus natus*, &c. Legates *a latere* are sent on the highest missions to the principal foreign courts, and as governors of provinces within the Roman territory which are called legations (*legazioni*),

when they are governed by a cardinal. Legates of a lower rank than cardinals are called *nunci apostolici* (apostolic messengers).

LEGATEE. [LEGACY.]

LEGAT'O (Ital. 'tied'), in music, a term used in opposition to *staccato*, implying that one note is tied to another, and represented by placing these marks $\sim$ above or below the notes intended to be joined. Where these *legati* appear, the notes are to be played in a smooth and gliding manner, each note on the piano to be held down till the next is struck.

LEGEND (from the Latin word *legendum*, 'a thing to be read'), is used commonly in the sense of fabulous or doubtful narratives between history and fiction, tales of superstition, or other subjects, in which credulity and imposture find free room for exercise. Thus legends have come to signify that which is usually rather matter of tradition than of written evidence. In our old authors the word occurs in its simple meaning.

Legend is also used technically to denote the words encircling a coin. To writing on tablets the word *inscription* is applied, which is also used instead of legend where a sentence, instead of encircling, occupies the place of a device on the coin.

LEGENDE, ADRIEN MARIE, an analyst, whose name must follow those of Lagrange and Laplace in the enumeration of the powerful school which existed in France at the time of the Revolution, was born at Paris in 1751, and died there January 10, 1833. He never filled any political post, or took any marked part in public matters: he was, we believe, no favourite of any government, and his scientific fame did not procure for him more than a very moderate competency.

The writings of Legendre are mostly extended applications of the integral calculus. In 1787 he was appointed one of the commissioners for connecting the observatories of Greenwich and Paris by a chain of triangles. Cassini de Thury had memorialized the British government on the expediency of this step, the execution of which was committed to General Roy on the English side, and to Legendre, Cassini, and Méchain, on the French. Much of the work was completed in 1787, and a memoir of Legendre, published in the volume for that year, upon some theoretical points, contains one of those simple and beautiful theorems which carry the name of their inventors with them for ever.

Legendre applied himself at an early period of his life to the development of those integrals on which the determination of the arcs of an ellipse and hyperbola depend. In the *Memoirs of the Academy* for 1786 are two papers on the subject written by him. His '*Exercices du Calcul Intégral*,' published in 1811, contain, among other matters of high curiosity, an extended view of the same subject. He continued to devote himself assiduously to the cultivation of this new branch of science, and in 1825 and 1826 he produced the two volumes of his '*Traité des Fonctions Elliptiques et des Intégrales Eulériennes*,' containing a digested system, with extensive tables for the computation of the integrals. The work was hardly published when the discoveries of MM. Abel and Jacobi appeared. These mathematicians, then both very young, had begun by looking at the subject in another point of view, and had produced

results which would have materially simplified a large part of Legendre's theories, if he had had the good fortune to find them. With a spirit which will always be one of the brightest parts of his reputation, Legendre immediately set to work to add the new discoveries to his own work; and in 1828 and subsequent years appeared three supplements, in which they are presented in a manner symmetrical with the preceding part of the work, and with the fullest acknowledgment of their value and of the merit of their authors.

To Legendre is also due the collection of the results obtained upon the Theory of Numbers, a subject to which he made very remarkable additions. The second edition of his '*Théorie des Nombres*' was published in 1808, and the third in 1830.

LEGHORN (*Livorno*) a large maritime city and seaport of the kingdom of Italy, is situated in 43° 33' N. lat., 10° 19' E. long., at the southern extremity of a low and partly marshy plain extending from the left bank of the Arno to the hills of Montenero, which end abruptly on the sea about 3 miles to the south. The city is 14 miles S. by W. from Pisa, 45 W. by S. from Florence, with both of which it is connected by railway, and had in 1861 96,471 inhabitants, of whom many are Jews. The town is neatly and regularly built; the streets are wide and mostly straight, and there is a fine square in the centre. The western district, called *La Nova Venezia*, is intersected with canals, by which the goods are carried in boats from the shipping in the harbour and landed before the warehouses of the merchants. Many of the private houses are handsome. The shops are well supplied with goods, and fitted up in good taste. The English and Lutherans have chapels and burying grounds, the Greeks a church, and the Jews a very handsome synagogue. The English burying-ground, situated on the ramparts, is adorned with numerous marble monuments—among others is that of Smollett, who died here. The town itself is little more than two miles in circumference; but two large suburbs, one beyond the north or Pisa gate, and the other to the south, called *Borgo Cappuccini*, have gradually increased to the size of towns, and have been included within the boundaries of the *Porto Franco*, wherein goods can be landed and warehoused, and exported again without paying duty. The outer mole, which is more than a mile in length, and joins the lighthouse, affords a pleasant walk. To secure increased shipping accommodation, a new harbour has recently been constructed for vessels of considerable tonnage, but the very largest still lie in the roads, where the anchorage is safe and good. The *Darsena*, or interior harbour or dock, is only fit for smaller vessels. Near the *Darsena* stands a fine colossal statue of Duke Ferdinand I., a great benefactor of Leghorn. The *lazzarettos*, of which there are three, outside of the town and on the sea-shore, are remarkable for their excellent distribution and perfect security, being surrounded by wet ditches, and furnished with extensive warehouses and convenient lodgings.

Leghorn is rather a commercial than a manufacturing town; it has, however, tan-yards, rope-walks, soap and candle factories, glass-works, establishments for the manufacture of coral ornaments, woollen caps, cream of tartar, borax, and sulphur. Steamers and

sailing vessels are built. The town has a casino or assembly-house, a theatre, and very good inns and coffee-houses. Educational establishments of all kinds are numerous.

Leghorn embraces all the foreign trade of Tuscany, and ranks as the greatest commercial emporium in Italy. The imports are either for consumption or for deposit. They consist of corn, cotton, hemp, wool, sugar, raw and manufactured silk, bronze work and jewellery, cotton and cotton yarn, spices and drugs, dye-stuffs, porcelain, gum, wine, spirits, tobacco, &c. Many of these articles of course enter into the exports, for the transit trade is very extensive. Other exported articles are oil, anchovies, paper and rags, straw hats, marble and alabaster, works of art, timber, cork, coral, tallow, potash, &c. The total value of the imports and exports amounts to about 6,000,000*l.* a year. The number of vessels that enter the harbour annually is over 5000, with about 500,000 tons cargo. The number of ships that clear are about the same in number, but the freights are somewhat less. Steamers ply regularly to *Civita-Vecchia*, Naples, Sicily, Genoa, Nice, and Marseilles.

Leghorn was made a free port by the Grand Duke Cosmo in the sixteenth century, and to this circumstance it owes its chief prosperity. The population of Leghorn is much increased during the summer season, in consequence of the large number of visitors who resort to it for its baths and mineral springs, the latter of which enjoy high medical repute. The town is altogether one of the most improving on the Continent.

LEGION. In a Roman consular army each grand division, corresponding nearly to a modern brigade, was so denominated; and the word indicates a selection of the individuals composing such division. The name is still occasionally given to a body of troops consisting of several regiments or battalions, when raised at a particular place or for a particular service.

The strength of a Roman legion varied at different periods. Romulus divided the men who were able to bear arms into legions of 3000 men, but under other rulers their numbers amounted to more than 6000. The legion declined under the later emperors, and in the time of Constantine did not number more than 1500 men.

The manner in which the soldiers were elected to serve in the legions is fully described by Polybius (book vi. ch. 1). When an army consisting of four legions was to be raised, the citizens of the proper ages being assembled on an appointed day in the capitol, the military tribunes drew out the tribes by lot, and from that which was first called they selected four men of nearly equal age and stature. Of these the tribunes who were appointed to the first legion chose one; those who were appointed to the second legion chose another; and so on. Afterwards the whole body of the tribunes chose four other men, and of these the tribunes of the second legion first chose one; those of the third legion then chose another; and so on, the tribunes of the first legion taking the last man of the four. In like order the election proceeded till the required number of men was obtained.

Immediately after the enrolment, the recruits for the legions being made to advance one by one, each was sworn to be obedient to his commanders, and to

execute all the orders which he should receive from them to the utmost of his power.

On the institution of regular bodies of troops by Romulus, he is said to have divided them (probably each legion) into companies of 100 men, and these were called *Manipuli*, from the bundles of grass which served as standards for the people who accompanied him when he attacked the palace of Amulius. The first mention of a cohort occurs shortly after the expulsion of the kings (Liv. ii. 11); and in the time of Polybius the legion was divided into ten cohorts, each of these into three manipuli (Polybius, b. 11), and each of the latter into two centuriae.

Servius Tullius is said to have divided the military force into five different classes of troops (Liv. i. 43), which were distinguished by their armour; but from the commencement of the republic, or nearly so, the order of battle consisted of three lines of troops, the *Hastati*, the *Principes*, and the *Triarii* (Liv. viii. 8). The *Vélites* (light troops or skirmishers) had no particular station.

All the three classes were completely armed with cuirass, helmet, and greaves. Their buckler was 4 feet long and 2½ feet broad, and five arrows were placed in its concavity, to be thrown when necessary. Each man was provided with a long and a short sword, the blade of the former being strong, and made either to cut or thrust; and he carried, besides, two javelins, or *pila* (Polybius, b. 6).

The front of the legion, when in order of battle, was formed by ten corps of the hastati, each corps being arranged with sixteen men in front, and ten in depth. The second line, or that of the principes, was of the same strength, and was drawn up in the same manner. The line of triarii consisted also of ten corps; but these had only ten men in front and six in depth. Every legionary soldier was allowed five feet in front, and as much in depth, in order that he might be enabled to make free use of his arms.

The cavalry of a Roman legion was divided into ten *tumæ*, of about thirty horses each, who, in order of battle, were drawn up with eight in front and four in depth. Each legion of the allies had, however, 600 horsemen; so that the cavalry of a consular army (consisting of two Roman legions and two legions of allies) amounted to 1800 men, who were disposed on the wings of the legion, in one line or two, according to circumstances. The legionary cavalry were furnished with cuirasses and helmets, and they were accompanied by light-armed horsemen, who served as archers.

LEGION OF HONOUR, an order of merit in France, instituted by Napoleon during the year 1802, as a recompense for military and civil services. The order consisted of five divisions: *chevaliers*, of whom the number was unlimited, *officers*, *commanders*, *grand officers*, and *grand crosses*. In the year 1815, on the second restoration of the Bourbons, the entire number of members of the different divisions of this order was 30,747. Louis Philippe distributed the decorations with a prodigal hand, and in 1843 there were no less than 49,417 members. This immense number had naturally detracted much from the value which was at first placed on the honour, and since the election of the present emperor only one appointment has been made for every two vacancies. Some of the privileges which Napoleon conferred on the

order, such as the right to vote at the electoral colleges, were abolished by the Bourbons, and the pensions were much reduced. The college of the legion is, however, still possessed of a considerable income (it was much augmented by the gift of a portion of the property of Louis Philippe), out of which large sums are paid as pensions to certain members of the order. The decoration, as now worn, consists of a cross of ten points of white enamel edged with gold. The points are connected with a wreath of laurel, and in the centre is the head of the emperor. It is worn attached to a red ribbon. Every Frenchman who belongs to the order must pass through the lower grades before he can rise to the superior rank. Candidates, except in special cases, must have served twenty years in time of peace in some military or civil capacity; exploits in war, or severe wounds, constitute special claims. The honour has from time to time been conferred on several eminent men in science and literature, and in this respect has not been confined exclusively to Frenchmen.

LEGISLATION. A magistrate who proposed a law in Rome for the adoption of the assembly of citizens was said *legem ferre* (as we say, to bring a bill into Parliament); and the law, if carried, was said to be *perlata*, or simply *lata*. Hence the term *legem lator*, or *legislator*, was used as synonymous with the Greek *νομοθέτης*, in the sense of a lawgiver. From *legislator* have been formed *legislation*, *legislative*, and *legislature* (the last word signifying a person or body of persons exercising legislative power).

Legislation means the making of positive law. A general command, or law, would be nugatory, if it was not applied in practice to the cases falling within its scope, and if the pains denounced for the violation of it were not inflicted on transgressors. The execution of the general commands, or laws, of a sovereign government is therefore an essential part of the business of a government. Accordingly, the ordinary functions of a government may be divided into the two classes of *legislative* and *executive*.

An *executive* command, or act, of a sovereign government is a special command issued, or act done, in the execution of a law previously established by the government. Executive commands or acts are of two sorts, viz., *administrative* and *judicial*. The distinction between these two sorts of executive commands or acts may (in conformity with modern phraseology) be stated as follows:—A judicial proceeding is a declaration, by a competent authority, that a person has (or has not) brought himself within the terms of a certain penal provision, or that he has (or has not) a certain legal right or obligation which another disputes with him. An administrative proceeding is for the sake of carrying a rule of law into effect, where there is no question about the legal culpability, or dispute about a legal right or obligation of a person. In an administrative proceeding the government functionary acts, or may act, spontaneously and from his own information; in a judicial proceeding he does not act until he is set in motion by others, and he can only take notice of the facts which the litigant parties bring before him. A judge cannot act until his court is (to use the French phrase) *seized*, or *saisi*, with the question; or (to use the language of our ecclesiastical courts) it is necessary 'to promote (or set in motion) the office of judge.'

The division of the functions of government into legislative and executive is not exhaustive, inasmuch as neither class comprehends acts or special commands not founded on a previous general command or law, in other words, *privilegia*; as well as treaties and other compacts of a sovereign government.

Positive law may be viewed from the two following aspects. First, it may be considered as an organic system, consisting of coherent rules, expressed in a technical vocabulary. Secondly, its rules may be considered singly, with reference to their end or object. Law viewed from the former aspect is properly the subject of the science of jurisprudence. [JURISPRUDENCE.] Law viewed from the latter aspect is the subject of a department of political science which is generally termed *legislative science*. Legislation is also concerned about the technical form, as well as the object, of a law; and therefore legislation requires the aid of jurisprudence.

The distinction between the technical form and the substance of a law is also important with reference to the question of *Codification*, i.e., the making of a code of laws.

The making of a code of laws may involve any one of the three following processes:—1. The formation of a new system or body of laws. 2. The digestion of written laws, issued at various times, and without regard to system. 3. The digestion of unwritten law, contained in judicial decisions and authoritative legal treatises. The *codices* of Theodosius and Justinian are examples of the digestion of written laws. [CONSTITUTIONS, ROMAN.] The 'Digest' or 'Pandects' of Justinian afford an example of the digestion of unwritten law. The English statutes for consolidating various branches of the criminal law, the bankruptcy laws, the customs laws, the distillery laws, &c., are instances of the digestion of the written law of England. The digestion of existing law, whether written or unwritten, requires merely juristical ability; the making of new laws requires, in addition to the knowledge and skill of the jurist, that ability which we have termed legislative. In other words, the making of new laws requires attention to their end, design, or object, and technical skill in the composition or drawing of them.

LEGITIM, or BAIRN'S PART OF GEAR, in Scotch law, is the legal share of the father's free movable estate falling to the children of the marriage at their father's death. When a father dies, leaving a widow and children, a tripartite division of his movable estate, one-third going to the widow as her *jus relicte*, another to the children in name of *legitim*; whilst the remaining third, or *dead's part*, if not disposed of by the father during his lifetime, goes also to the children as his next of kin. If the deceased has left heritable estate, his eldest son, as his heir-at-law, is excluded from a share of the legitim, unless he chooses to collate the heritage with the younger children.

LEGITIMACY. All children are legitimate who have been procreated in lawful wedlock, or, in Scotch law, have been legitimated by the subsequent marriage of their parents. [LEGITIMATION.] The presumption of legitimacy arising in favour of a child born of a mother who at the time of conception was lawfully married, can now be rebutted only by the

clearest evidence that the husband could not possibly be the father of the child.

LEGITIMATION, the act by which children born in bastardy are made lawful children, may take place according to Scotch law in two ways, either by the subsequent marriage of their parents, or by royal letters of legitimation.

1. *Legitimation per subsequens matrimonium*, a remedy borrowed from the law of Rome, is competent only when the parents at the time of the birth, and also at the time of the marriage, were domiciled in Scotland, and were under no legal impediment to marry at the time of the procreation of the child. The fact of the parties having contracted an intermediate marriage between the date of the birth of the child and their subsequent marriage, does not operate any bar to legitimation. But a child legitimated in this way cannot succeed to real estates in England, for in that country legitimation by subsequent marriage is unknown.

2. *Legitimation by royal letters* operates only to the effect of dispensing with the Crown's right of succession to the intestate estate of the father of the bastard. [BASTARD.]

LEGNANO. [VERONA.]

LEGUMIN, a peculiar vegetable product obtained by Braconnot from peas, and which he considers as a vegetable alkali. It appears to be a substance intermediate between gluten and vegetable albumen; it differs from the first in being insoluble in alcohol, and from the last in readily dissolving in the alkaline carbonates. It contains some sulphur, and also azote, but less than animal albumen. It exists in peas and beans to the amount of about 18 per cent.

LEGUMINOSE, or FABACEE, a very extensive natural order of plants inhabiting the coldest and hottest, the driest and dampest, parts of the world; assuming the greatest varieties of form and size, some being among the smallest of flowering plants, others forming the largest trees in tropical forests. They vary also in an extraordinary degree in their sensible qualities, some being eatable, as peas, beans, and other pulse; others poisonous, as *Piscidia*, *Tephrosia*, and *Cytisus*; some secreting a fragrant volatile oil, others destitute of all trace of such a substance.

The species amount to some thousands, and are conveniently divided into three sub-orders, *Papilionacee*, *Casalpiniacee*, and *Mimosee*.

Papilionacee have what are called papilionaceous flowers, resembling a butterfly; and it is here that the great mass of the order occurs, especially in the colder parts of the world. Peas, beans, clover, sainfoin, lucerne, liquorice, indigo, medicks, and trefoils, lupines, and numerous other common European genera, belong to *Papilionacee*.

Casalpiniacee includes the Cassia, which furnishes the senna-leaves of the shops; and also the Tamarind and Algaroba fruits, the trees yielding logwood, Brazil-wood, Sapan-wood, &c., and *Hymenaea*, from which Gum-animi is procured.

Mimosee comprehends the species yielding the gums Arabic, Senegal, Sassa, and others. *Catechu* is the extract of the astringent bark of *Acacia catechu*, and rosewood is said to be the timber of some *Mimosa* inhabiting the interior of Brazil. One of the most striking phenomena among the plants of this order is the excessive irritability observable in

the leaves of certain species of *Mimosa*, such as *M. pudica*, *M. sensitiva*, &c., which are hence called Sensitive Plants. It is, however, a special peculiarity, and not one of general occurrence, unless the folding up at night of the leaves of the whole sub-order be regarded as an instance of the same irritable quality in a low degree.

LEIBNITZ, GOTTFRIED WILHELM, jurist, historian, mathematician, and metaphysician, the most learned of modern philosophers, and the eclectic founder of German philosophy. This great German was born on the 3rd of July, 1646, in Leipzig, and was descended of an ancient family, distinguished in civil and ecclesiastical affairs. When he was only six years old his father died, and his religious mother, who lived till 1664, and who had herself been carefully trained in the family of a Lutheran professor of theology, devoted herself exclusively to his education. Both his parents were Lutherans, and his early training probably induced much of the theological character by which his subsequent speculations are distinguished. The first twenty years of the life of Leibnitz were spent almost entirely in Leipzig, where he attended the famous Nicolai school, and afterwards the university, which he entered in 1661. Many anecdotes are recorded of his extraordinary precocity. He has himself, in the 'Pacidii Introductio Historica,' given an interesting account of the self-educating process his mind underwent in these early years, which throws light on the type of his philosophical development afterwards. The universality so conspicuous in the man was illustrated in the universality of the young student. Almost every part of knowledge in turn engaged his attention. He studied history and the ancient classics with enthusiasm, extending his researches far beyond the conventional track in which his narrow-minded teachers sought to restrain him. But the strength of his mind and the bent of his genius were more fully disclosed when he entered logic and philosophy. He read Aristotle, Plato, and Plotinus, and luxuriated in the subtleties of the scholastic metaphysics—that stimulant of the human understanding for so many hundred years. Even at this early period he was no stranger to the literature of theology, for he studied the deep controversies about election and grace in the works of St. Augustine and Luther. During his academical course, the philosophical writings of Des Cartes, published about twenty years before, fell into his hands, and by them, like his contemporary Locke, he was greatly influenced. In his recorded experience, at the age of sixteen, may be found the dim forms of the problems which engaged his thoughts during the remainder of his life. For days together, as he informs us in his 'Personal Recollections,' he was wont to pursue his walks alone in the woods of Rosenthal, near Leipzig, revolving the first principles of this mysterious life to a reflex consciousness of which he was becoming awake. The intellectual movements of the true metaphysician may be discovered in his first printed treatise, 'De Principio Individui,' written on occasion of his promotion to the degree of bachelor of philosophy, when he was only seventeen years of age. This work was followed, about three years after, by those philosophical speculations on mathematics and a universal language contained in his 'Dissertatio de Arte Combinatoria.' Having taken his degree

in arts, Leibnitz devoted himself professionally to the study of law. When he had completed his twentieth year he applied for the degree of doctor of law, with the intention of entering afterwards on the business of professional life. For the accommodation of other candidates the university postponed this academical honour to Leibnitz, who thereupon resolved on expatriating himself. He left Leipzig, and Saxony his native country, and in 1666 went to the University of Altdorf, where he received his degree in law the same year.

Leibnitz led a somewhat desultory life for several years after this. At Nuremberg, in 1667, he met the distinguished statesman and scholar, the Baron Von Boineburg, who had been long prime-minister of the elector of Mentz, and who was then living at Frankfort-on-the-Maine. Boineburg in a great measure determined the subsequent life of Leibnitz. In that year the young philosopher accepted his invitation to transfer his residence to Frankfort, where he became his secretary, and enjoyed the society of men of letters and affairs. During his residence at Frankfort he was patronized by the elector of Mentz, and was much engaged in legal and diplomatic labours as well as in literary pursuits; yet his mind was all the time animated by the great idea of his life. His political relation to the elector occasioned visits by Leibnitz to other courts in and around Germany, and also to Paris, where he went in 1672 to divert Louis XIV. from a suspected attack on Germany, by the project of a French crusade to Egypt and the East. The four following years were for the most part spent in Paris by Leibnitz, in the capacity of councillor to the elector of Mentz. In the circles of that brilliant metropolis he was a conspicuous object; and he found the place so congenial to him that he more than once formed the plan of making the French capital his permanent residence. In 1673 he visited London for a short time, where he became a member of the Royal Society, and made the acquaintance of many English savans. To this period in his life belongs his immortal discovery of the differential calculus, which has placed him in the foremost rank of mathematicians. It was followed by the famous controversy regarding an alleged priority of discovery by Sir Isaac Newton. In this controversy were discussed the difference between the calculus of Leibnitz and the Newtonian method of fluxions, the time of the discovery of the former, and its superiority over the latter. Leibnitz communicated his calculus to Newton in 1677, after he had received a letter from Newton containing his fluxional method concealed in two sentences of transposed characters. Newton then broke off the correspondence. Leibnitz promulgated his discovery in 1684 in the 'Acta Eruditorum,' but made no allusion to his former correspondence with Newton, whose 'Principia,' containing an explanation of the fluxionary method, appeared in 1686. The publication of the 'Principia,' which Leibnitz habitually disparaged, widened the breach between the two philosophers.

The year 1676, when he was thirty years of age, is an era in the life of our philosopher. Then commenced that connection with the court of Hanover which lasted during the remaining forty years of his life. Henceforward Hanover was his home, in which this sage held a succession of political and literary

offices under Duke John Frederick and his successors, the electors Ernest Augustus and George Lewis, the latter of whom became George I. of England two years before the death of Leibnitz. The variety of his aims during these forty years is marvellous, and amid them all the development of his speculative genius continued to advance. History, politics, languages, mathematics, geology, chemistry, medicine, metaphysics, and theology, in turn secured his attention, and his busy spirit collected the varied learning of each department. In history he worked for years on the antiquities of the house of Brunswick and the early annals of Germany. These historical researches became the great labour of his life. Experience of the difficulties of archaeological research suggested to him the comparative anatomy of languages as a means for aiding his efforts to travel back into the past. To the study of languages he accordingly applied himself with extraordinary zeal. He laid ambassadors and Jesuit missionaries under contribution for philological facts. In prosecuting this one department of investigation he maintained an immense correspondence. Not content with the records of the past contained in the words and works of man, he interrogated the globe itself. In the speculations on the physical vestiges of its early history, contained in his posthumous treatise, entitled 'Protogæa,' we find most interesting anticipations of recent geological hypotheses, and a remarkable familiarity with geological facts. Throughout the forty years of his connection with the court of Hanover Leibnitz maintained his literary intercourse with unabated energy. His correspondence forms a very important part of his philosophical writings. In this period he, in fact, settled and extended the foundations of the literary republic of Europe. During the later years of his life he was engaged in a project of ecclesiastical union. About 1697 he promoted a plan, encouraged by the courts of Hanover and Berlin, for a general union of Protestants against Rome, and especially of the two great sections of Protestantism, the Lutheran and the Reformed. These negotiations, in which Jablonski, Molanus, and others took part, gradually proved abortive, and in a few years Leibnitz abandoned his effort.

Leibnitz was able in an unusual degree to unite the practical and the purely speculative life. But amid his varied political and ecclesiastical projects, and his marvellous literary activity, the metaphysical tendency always retained its ascendancy in his mind. His philosophical principles were gradually matured after his settlement in Hanover in 1676, and were given to the world from time to time in a fragmentary form, through reviews, letters, and occasional tracts. Many of these remained unpublished in the royal library of Hanover until long after his death, and his most recent editors are still drawing largely upon the immense stores which his MSS. supply. He has produced no single work which contains a systematic exposition and defence of his philosophical creed. His 'Meditationes de Cognitione, Veritate, et Ideis,' which contain his famous distinction of intuitive and symbolical knowledge, and his exposition of the logical degrees of conception, appeared in 1684, in the 'Acta Eruditorum' of Leipzig. His system of pre-established harmony is referred to in a letter to Arnauld in 1690, and more fully expounded in his

tract, entitled 'Système Nouveau de la Nature,' published in the *Journal des Savans* for June, 1695, as well as in other articles or letters in that journal in the following year. His theory of Monads, indicated in his earlier fragments on substance and cause, as well as in his criticisms of Des Cartes and Malebranche, and which pervades his later philosophical works, is expounded in 'La Monadologie,' written in 1714, and recently published from the Hanover manuscripts. The 'Theodiciée,' published in 1710, when Leibnitz was in his sixty-fourth year, is the most generally known and, except the 'Nouveaux Essais,' the largest of all his philosophical works. It holds a foremost place among works on the philosophy of theology. Its avowed purpose is to refute the scepticism of Bayle, who disputed the consistency of faith and reason, and it was perhaps indirectly suggested by the life-long efforts of Leibnitz to restore the unity of Christendom. The design of the 'Theodiciée' is, by a scheme of optimism, to reconcile the existence and continuance of evil in the universe with the moral government of God—to meet the difficulty common to all religions—the fundamental metaphysical problem of Christianity. The subject had been pondered by Leibnitz for many years. But this mighty spirit was now to pass away. Leibnitz had suffered from occasional periods of ill health for several years. In November, 1716, when he had to prepare his reply to an attack by Dr. Clarke, and was busied with his 'Annals of the house of Brunswick,' of which the first volume had appeared in the preceding year, and when he was contemplating a comprehensive exposition of his entire system of philosophy, he was suddenly overtaken by death. During the last day of his life, we are told, he conversed with his physician on the scientific nature of his disease, and on the doctrines of alchemy. Towards evening his servant asked if he would receive the Eucharist. 'Let me alone,' he said, 'I have done ill to none. All must die.' He raised himself on the bed and tried to write. The darkness of death was gathering round him. He failed to read what he had written, and lying down, covered his face with his hands. In a few minutes he ceased to breathe, on the evening of the 14th November, 1716.

The metaphysical philosophy of Leibnitz may be regarded as a reconstruction of Cartesianism on a broader basis, and with important modifications, suggested by the consequences into which the Cartesian system had been resolved by Malebranche and Spinoza. The systems of Locke and Leibnitz are in truth reactions, in opposite directions, against the earlier philosophy as involving these consequences. Cartesianism, which places the essence of matter in extension, and of mind in thought, tends to eliminate altogether finite causes and substances. Malebranche accordingly rejected secondary causes, and virtually resolved all the changes in the universe into the agency of God. Spinoza, advancing further, deduced all finite existence from the One Absolute Substance. The metaphysic of Leibnitz is fundamentally a theory of the essential activity of the substances or monads of existence, which possess, according to him, a power of spontaneous development. In these unextended forces or monads we obtain, says Leibnitz, the *a priori* idea of substance. Their individuality consists in the series of changes through which each

passes. These changes are termed perceptions. Some perceptions are unconscious, and among these are the elements of which the material world is the issue. There are also the self-conscious souls of men, containing in themselves the seeds of necessary truth, developed through experience. Creation implies the existence of the *Monas Monadum*, or Supreme Substance, whence all that is finite has been derived, and in which it all finds its explanation. The universe is thus a vast collection of unextended spiritual forces, which evolve themselves in a pre-established harmony or cosmical order, and which, in its final issues, constitutes a scheme of optimism. The created universe is a harmonious theocracy which expresses the attributes of the one perfect Being. From his eternal throne its several streams of elementary existence have taken their rise. They have flowed, and they must continue to flow, in the courses into which he sent them in the beginning; and notwithstanding the dark shades in which many of them are enveloped, they are recognized by Omniscience as the only possible, and therefore most glorious illustration by creation of the pure fountain in which they originated. The speculations of Leibnitz, like those of Berkeley, though by a different route, thus conduct to immaterialism.

Eckhart has recorded some particulars regarding the personal appearance and manner of life of this philosopher. He was of middle stature, rather spare in person, and short-sighted. His constitution was vigorous. Like Descartes, Spinoza, Locke, Hume, and Kant, Leibnitz was never married. He had no domestic establishment, and no fixed hours for his meals, which he took when convenient for his studies. These were pursued without intermission, and often for days together he did not leave his chair. In his journeys he often in his carriage carried on mathematical or philosophical investigations, which were afterwards published in the journals. A great part of the '*Nouveaux Essais*' is said to have been written in this manner. In the course of his immense reading it was his habit to make extracts in his commonplace book, and to note, often on fragments of paper, his critical remarks on what he read. His extraordinary memory made it almost unnecessary for him to refer afterwards to what he thus wrote, for Leibnitz was one of those prodigies of memory of whom anecdotes are recorded. He forgot almost nothing that he had once read or heard. In his old age he could recite the most beautiful passages of the ancient classics, and whatever else he had read in his youth. But though he read much he reflected more. He is illustrious, like our own Hamilton, for the mental power which can unite extraordinary reading with a ceaseless energy of thinking. In most parts of knowledge it may well be said that he was self-taught, and he always struggled for deeper insight into things than that attained by other minds. He preferred solitary meditation to conversation, but when once roused in social intercourse he spoke with interest, and even indulged in playful sallies. In accordance with his liberal and tolerant spirit, it was his habit to speak well of others, and to put the best construction on their words and actions. 'When I err in my opinion of men,' he was wont to say, 'I prefer to err on the side of charity, and so too as regards their writings. I seek there for what is

worthy of praise, rather than of blame; and there are few books or persons whence I may not in some form draw wisdom and useful instruction.' Such was the spirit of Leibnitz, and to these comprehensive sympathies we may trace the modern philosophy of the history of man and of human opinion.

A collected edition of the works of Leibnitz was published by Dutens in six vols. 4to, at Geneva, in 1768. His philosophical works were published three years earlier by Raspe, and republished, with many additions, in 1840, in the well-known edition of Erdmann. Since then various monographs and tracts from the Leibnitzian MSS. at Hanover have appeared, and a complete edition of his works has recently been published.

LEICESTER. [LEICESTERSHIRE.]

LEICESTER, ROBERT DUDLEY, EARL OF, was born about 1531. His father, the duke of Northumberland, was executed for his adherence to Lady Jane Grey. The son was imprisoned for a time, but was soon liberated, and afterwards made master of the ordnance by Queen Mary. On the accession of Queen Elizabeth he became a favourite, and received at her hands gifts and titles, the earldom of Leicester being the last and highest. To retain this favour, or, as it has been suggested, in order to marry Elizabeth, Dudley is suspected of having, in 1560, caused the death of his wife, Amy Robsart, whom he had married when very young. He is also accused of having instigated an attempt which was made to poison Lady Sheffield, by whom he had a son; and for this crime, if he committed it, he doubtless had a similar motive. His marriage with the widow of Lord Essex was very nearly depriving him of the queen's favour; but notwithstanding her temporary anger, his influence over her remained undiminished. This marriage, too, involved another case of suspicion: Lord Essex had died in a very unaccountable manner two days before it took place.

Successful as a courtier, Leicester proved his inefficiency as a soldier by his conduct of two separate commands with which he was intrusted in the Low Countries in 1585 and 1587; and it was found necessary in both cases to recall him. The last trust conferred upon him was in 1588, when he was appointed lieutenant-general of the infantry mustered at Tilbury Fort, for the purpose of resisting the Spaniards. This was the year of his death, which took place at Cornbury, in Oxfordshire. It was in the previous year that he advised Elizabeth to put Mary, queen of Scots, privately to death.

LEICESTERSHIRE, a central English county, bounded N. by Nottinghamshire, N.E. by Lincolnshire, E. by Rutlandshire, S.E. by Northamptonshire, S.W. by Warwickshire, and N.W. by Derbyshire. It is included between $52^{\circ} 24'$ and $52^{\circ} 59'$ N. lat., and between $0^{\circ} 39'$ and $1^{\circ} 37'$ W. long. The greatest length, N. by E. to S. by W., is 44 miles; the greatest breadth, at right angles to the length, is 40 miles. The area is about 800 square miles, or 514,164 acres, of which about 480,000 are estimated to be arable, meadow, or pasture. The population in 1861 was 237,412—115,426 males, and 121,986 females—being an increase of 7104, or 3 per cent., since the previous census. There were in 1861 51,894 inhabited houses in the county, 2673 uninhabited, and 211 building.

Surface, Rivers, &c.—The surface of Leicestershire consists almost entirely of gently rising hills. The north-eastern part is occupied by the southern extremity of the Kesteven Cliffe Row. The south-eastern portion is occupied by the hills which separate the basin of the Soar from that of the Welland. The north-western portion constitutes the district which, though now bare of wood, retains its ancient designation of Charnwood Forest. This district is occupied by a group of hills of inconsiderable elevation, but of a rugged character, with distinct and sharp prominences. Bardon Hill, between Leicester and Ashby, 853 feet high, has one of the most extensive prospects in England.

The eastern portions of the county are mostly occupied by the oolite, the lias, and the intermediate formations. The rest of the county, with the exception of Charnwood Forest, the coal-fields near Ashby-de-la-Zouch, and some isolated hills of mountain limestone to the north-west of Charnwood Forest, is occupied by the new red sandstone. The Ashby coal-fields lie one to the north-east, the other to the south-west of the town, and extend into Derbyshire. Isolated beds of mountain limestone are quarried in many places. Charnwood Forest district is occupied by rocks of the transition series, syenite, granite, greenstone, and slate. Coarse slate, gypsum, limestone, freestone, and brick-clay are procured within the county.

Leicestershire is chiefly included in the basin of the Trent, which just touches the county, and for a few miles divides it from Derbyshire. The principal tributary of the Trent belonging to this county is the Soar, which is formed by the junction of several small streams that rise near the south-western border of the county; it flows past Leicester and Loughborough to the Trent, which it joins about 12 miles E.S.E. of Derby. It is navigable for barges from there to Leicester. The Wreak rises in Rutlandshire, and joins the Soar near Mount Sorrel. The Anker skirts the border of the county. Near Atherstone it joins the Tame, a feeder of the Trent, at Tamworth. The Sence joins the Anker. The Mease, the Devon, and the Smyte are small feeders of the Trent. The Avon, a tributary of the Severn, forms the boundary of the county for seven or eight miles on the southern side. The Swift, a small stream which flows by Lutterworth, falls into it. The Welland forms part of the Northamptonshire boundary of the county.

Leicestershire is traversed by the Midland Company's Railway, and is connected by canals with all parts of the kingdom.

Climate and Agriculture.—The climate of Leicestershire is mild and genial, without being so moist as in those counties which lie nearer the Atlantic. There are few high hills to intercept the clouds. The soil is loamy, without the extremes of stiff clay, loose sand, or chalk. The most fertile soils are almost invariably kept in pasture, for which this county is pre-eminent. Out of the entire surface, more than one-half is in permanent grass. The quantity of woods or wastes is very small. Grazing and breeding cattle and sheep are the chief objects of the Leicestershire farmers, and they have succeeded admirably both with oxen and sheep. The manure thus brought upon the fields, and the large culture of turnips and

green crops for the cattle, keep the arable land in good condition. Farms are of all sizes, and generally held by tenants at will. Rents are 30s. per acre per annum, exclusive of tithes and rates, for medium land; but sometimes 4*l.* to 5*l.* is given for good land near the towns. The cheese is generally made from 30 lbs. to 50 lbs. weight, the average yield per cow being from 3 to 3½ cwt. annually.

The natural meadows along the banks of the rivers are considerable, and most of them of excellent quality. The produce in hay is from 1½ to 2 tons per acre.

The county contains many large dairies, and produces excellent cheese, especially the Stilton cheese, most of which is made here. The principal breed of cattle in Leicestershire is the improved long-horn. The Leicestershire sheep are also renowned. They are large, with very long wool, and fatten very readily at an early age. This county is also pre-eminently noted for its breed of horses, hunters and large black cart-horses being reared in large numbers at Melton, &c. The rich pasture favours the rearing of this useful animal. Hogs have been improved in Leicestershire, as well as other animals.

Trade and Manufactures.—Coal and some iron and lead are wrought in Leicestershire, which is also the principal seat of the woollen hosiery manufacture. Hard red granite is quarried at Mount Sorrel.

Divisions and Towns.—Leicestershire is divided into six hundreds and more than 200 parishes. It is in the diocese of Peterborough and province of Canterbury, and in the Midland Circuit, the assizes being held at Leicester. For parliamentary purposes the county is divided into North Leicestershire and South Leicestershire, each of which returns two members to Parliament; besides which, two members are returned for the borough of Leicester: total, six. In 1865 the number of voters on the parliamentary register was—in the northern division, 4767, in the southern, 6283. There are eight polling-places in each division, Leicester being the place of election for the southern, and Loughborough for the northern.

The following are the principal towns, with the population of each in 1861:—

Ashby-de-la-Zouch, a market town, is situated on the Mease, a tributary of the Trent, 17 miles N.W. from Leicester, on the Midland Railway. Originally it was called Ashby; it received the distinctive addition of De-la-Zouch from the Zouches who were formerly lords of it. Ashby contains an ancient and handsome church. On the south side of the town stand the ruins of Ashby Castle, in which Mary, queen of Scots, was imprisoned. Woollen and cotton stockings, hats, and bricks are the chief articles of manufacture. Coal and ironstone are worked in the neighbourhood of the town, and there are some iron smelting works. There is a canal from the Coventry Canal Navigation to the neighbourhood of Ashby. Population of the parish, 6958; of the town proper, 3772. Ashby-de-la-Zouch was made widely known by Scott's brilliant novel of 'Ivanhoe,' as the scene where he laid the famous passage of arms described in that work.

Bosworth (commonly called *Market Bosworth*) is situated on an eminence, 12 miles W. from Leicester. The decisive battle between Richard III. and the earl of Richmond, when the death of the former,

after a bloody struggle of two hours' duration, terminated the long strife between the houses of York and Lancaster, was fought August 22, 1485, on a plain about one mile south of Bosworth. On an eminence called Crown Hill, Lord Stanley placed the crown upon the head of the victor, Henry VII. The population of the parish is 2376, who are partly employed in the knitting of worsted stockings.

Hinckley is on the Chester and Liverpool road, 12½ miles S.W. from Leicester. The church is large and ancient. The staple manufacture of the town is that of coarse stockings. There are also some ale breweries. The town of Hinckley is a polling-place for the southern division of the county. It is a market town, and a small part of the parish extends into Warwickshire. Population of the town proper, 6344; of the entire parish, 7315.

Leicester, a parliamentary and municipal borough, and the county town of Leicestershire, is on the east bank of the Soar, across which there are five bridges. It is 20 miles E.N.E. of Rugby. The 'Jewry' wall, a fragment 70 feet long, and a bank, called Raw Dykes, outside the town, are supposed to be remains of *Ratae* or *Rage*, under which name it was known to the Romans. It is supposed to have been on the line of the Via Devana. It was a populous Saxon city at the time of the Conquest, and was first chartered by King John. In the eighth century it was the seat of a bishopric.

The streets are generally well built, and it is well drained, lighted, and supplied with water. The most ancient church is St. Nicholas. It is chiefly of Norman architecture. St. Mary's Church is a large building, partly of Norman, partly of Early English architecture. The church of St. Martin is an ancient cross church, partly of Early English and partly of Perpendicular architecture. This church is the largest in Leicester. All Saints is a small church, chiefly in the Early English style. St. Margaret's is a handsome church, partly Early English, with a lofty Perpendicular tower. In St. Margaret's parish is a district church, erected in the Perpendicular style. There are two other churches and seventeen chapels in the town.

The borough gaol and house of correction are modern buildings. A new county gaol and house of correction have been built on the south side of the town. The other public buildings are—the assize hall, formerly the castle hall, 178 feet long; the guildhall, or old hall of the Corpus Christi Guild; the corn exchange (in the market-place); county and assembly rooms, a concert hall, mechanics' institute, museum of the Philosophical Society, town library, theatre, five banks, Albion baths, on the New Walk, a promenade one mile in length; Church of England collegiate school, in the Tudor style; Wigston's free grammar-school; Trinity hospital, founded in 1354, by Henry le Bossu, earl of Leicester; county infirmary, union workhouse, and county lunatic asylum. The borough has many valuable charities, including, besides several hospitals, Newton's charity for the support of schools; Johnson's consanguinitarian almshouses; a female asylum; green-coat, national, and British and foreign schools. A cemetery, of 25 acres in extent, was laid out in 1849.

The spring and summer assizes and courts of quarter sessions are held in Leicester. There is

direct communication by railway with Birmingham, Burton, Lichfield, Stamford, Market Harborough, Northampton, Bedford, Rugby, Leamington, and Melton. The distance from London by the Midland line is 97½ miles, or by road, 96 miles.

This town is the principal seat in England for the manufacture of woollen and other hosiery, first introduced in 1680. About 10,000 persons are thus employed. Lace, elastic fabrics, and boots and shoes are also extensively made. It is the centre of a great agricultural and wool-raising district.

Leicester has returned two members to Parliament since the time of Edward I. The municipal borough is divided into seven wards, and is governed by fourteen aldermen and forty-two councillors. The parliamentary and municipal limits are co-extensive, being the same as those of the old borough and liberty. Population 68,056, inhabiting 14,595 houses. The excess of females over males is nearly 5000. In 1851 the population was 60,584. The number of parliamentary electors in 1866 was 4762, including more than 1000 freemen. The borough covers altogether 3960 acres, and includes six whole parishes, with parts of others. The town is built at an altitude of 208 feet.

This place was called *Ledicester* at the making of Domesday survey, which enumerates as many as eight churches here. The castle, rebuilt on a large scale on the site of a fort called Newarks by John of Gaunt, was dismantled in the Civil War. In 1530 Cardinal Wolsey died in Leicester Abbey, now in ruins.

Loughborough, a market town, is 11 miles N. by W. from Leicester. The church is a handsome building in the Perpendicular style. There is also a Burton foundation school, and five schools in connection with it, a union workhouse, barracks, a public library, news room, and theatre. The chief manufactures are hosiery, bobbin-net lace, cotton goods, and shoes. The Leicester Navigation and the Loughborough Canal, communicating with the Trent and the Soar, tend much to the prosperity of the place. There is a branch railway from Leicester to Loughborough. Population of the town, 10,830; of the entire parish, 10,955.

Lutterworth, a market town, is 13 miles S. by W. from Leicester. The church is a large handsome building, containing a portrait of its rector, the reformer Wycliffe (who died here in 1384), and a part of his pulpit. The town is on the Swift, a tributary of the Avon, and on the Midland Railway. The inhabitants are employed in manufactures of hosiery and ribbons. Population of the town and parish, 2289.

Market Harborough, a market town, is 14½ miles S.E. from Leicester. It stands on the north bank of the Welland, and has a Gothic church, a town-hall, a union workhouse, and considerable manufactures of carpets and tanneries. Market Harborough was the head-quarters of Charles I. before his defeat at Naseby. It is in the parish of Bowden Magna, the population of the township being 2302.

Melton Mowbray, a market town, is 15 miles N.E. from Leicester. The town is in a valley, on the river Eye, near its junction with the navigable Wreak, over which are two bridges. The church is large, in the Gothic style. The chief manufacture is bobbin-net lace. Population of the parish, 4936;

of the town proper, 4047. At Melton is a station of the Midland Railway, and stabling for 800 horses, belonging to the members of the subscription fox hunt. Pork pies, for the London market, are extensively made here.

Mount Sorrel, probably *Mount Soar Hill*, is 7 miles N. by W. from Leicester on the road to Loughborough. The town is in a very romantic situation, on the side of a steep hill of red granite, on the left bank of the Soar, and consists chiefly of one street. There is a small market-house. The principal manufacture is of stockings. Population of the chapelry, 1754. It is in the parishes of Rothley and Barrow-on-Soar, and has a station on the Midland Railway.

History, Antiquities, &c.—Leicestershire was anciently comprehended in the territory of the Coritani; and when the Romans had subjugated Britain, and divided it into provinces, it was included in the province of Flavia Cesariensis. A Roman milestone, portions of wall, and numerous coins, urns, household utensils, and tessellated pavements of Roman work, have been met with near Leicester. South of Leicester town are two remarkable parallel embankments, called the Raw Dykes, extending about three furlongs in length, and about sixteen yards apart. They have been commonly regarded as the limits of a race-course, and as of British origin; but neither of these points is ascertained. There are many traces of Roman encampments in the county. The Roman roads named Watling Street, Fossway, Via Devana, and Saltway, cross portions of the county. Venonæ, or High Cross, was the principal Roman station.

During the Heptarchy, Leicestershire was included in the kingdom of Mercia. In the year 680, or according to others 737, Leicester was made the seat of a bishopric, which existed one or two centuries. By the treaty between Alfred and Guthrun the Dane (in 878 or 880), Leicestershire was included in the Danelagh or Danish territory; and Leicester became one of the great Danish burghs. It was recovered by the Saxons during the reign of Edward the Elder.

Upon the Norman Conquest, Leicestershire was divided between the followers and relatives of the Conqueror. Several of these or their descendants, to secure the territory thus acquired, erected castles or repaired older ones at Leicester, Mount Sorrel, Shilton, Whitwick, Groby, Hinckley, Donnington, Melton Mowbray, Ravenston, Thorpe, Sauvey, and Belvoir. There are abbey remains at Leicester and Gracedieu; and ancient castles at Ashby-de-la-Zouch, Donnington, and Bradgate, where Lady Jane Grey was born. The present Belvoir Castle is a more modern edifice.

In the civil war of Charles I. the men of Leicestershire seem generally to have taken the side of the Parliament.

LEIGH. [LANCASHIRE.]

LEIGHTON, ROBERT, D.D., Archbishop of Glasgow, a divine celebrated for his moderation and enlightenment during a time of great excitement. He presided over the University of Edinburgh; but when Charles II. attempted to introduce Episcopacy into Scotland, he was nominated to the bishopric of Dumbane. His conduct won him the affections of even the most rigid Presbyterians. He was afterwards induced to accept the archbishopric of Glasgow, which, however, he resigned, and retired to England, where he died in 1684.

LEIGHTON BUZZARD. [BEDFORDSHIRE.]

LEININGEN, formerly a county situated between the Lower Palatinate and the bishoprics of Spire and Worms, gives title to one of the German princely houses. The principal line obtained in 1779 the dignity of princes of the empire. In 1803 it lost its possessions on the left bank of the Rhine, and obtained, instead, a territory of 545 square miles, 425 of which are in Baden, 110 in Bavaria, and 10 in Hesse-Darmstadt. The principality was mediatised in 1806; but though no longer an independent prince, Prince Leiningen retains his wealth and rank. His possessions are within the territories of Baden, Bavaria, and Hesse. The prince's residence is at Amorbach, in the Bavarian Odenwalde, which has a population of 3400. The religion is Lutheran. There are four other branches of the house of Leiningen, two Lutheran and two Catholic; the head of each branch has the title of count.

LEINSTER, a province of Ireland, containing the counties of Carlow, Dublin, Kildare, Kilkenny, King's County, Longford, Louth, Meath, Queen's County, Westmeath, Wexford, and Wicklow. It lies between 52° 6' and 54° 7' N. lat., and between 6° and 8° 3' W. long. It is bounded E. by the Irish Channel, S. by the Irish Channel and the county of Waterford, W. by Tipperary, Galway, Roscommon, and Leitrim, and N. by Cavan, Monaghan, and Armagh. The greatest length, from the mouth of Waterford Harbour to the head of Carlingford Bay, is about 138 miles; the greatest breadth, from the Shannon, a little below Shannon Harbour, to Dalkey, near Kingstown, is about 80 miles. The entire area is 4,940,319 statute acres, and the population at the last census was 1,457,635, of whom 1,252,553 are Roman Catholics.

Of the four provinces of Ireland, Leinster possesses the greatest advantages in point of soil and surface, being little encumbered with mountains, and having consequently superior facilities for internal communication. The navigable Shannon forms part of its western boundary, and the navigable Barrow intersects its central and southern counties. The Boyne also, the basin of which lies within its north-eastern limits, is partly navigable, and the Royal Canal and Grand Canal traverse it from east to west. The coast is inferior in point of natural harbours to that of the remainder of the island, but it is more sheltered from the prevalent winds.

Upon the coming of the English in 1170, the present province was divided into the two petty kingdoms of Meath and Leinster, and embraced also a part of the then kingdom of Ulster, in the present county of Louth. The first counties elected were those of Dublin, including the present county of Wicklow; Meath, including the present Westmeath and Longford; Louth; Kildare, including the present King's and Queen's counties; Carlow, Kilkenny, and Wexford. Meath was divided into Meath and Westmeath in the reign of Henry VIII.; King's County and Queen's County were separated from Kildare, and erected into separate counties, in that of Mary; Longford was made shire-ground in the time of Elizabeth; and Wicklow was finally separated from Dublin and made a county in the reign of James I.

The ancient kingdom of Leinster, including all the

counties south of Meath, with the exception of Dublin, was inherited by the descendants of Eva, daughter of Dermot MacMurrough, and wife of Earl Strongbow. Meath was bestowed on Hugh de Lacey, and descended to the families of De Verdon and Geneville. Almost all the inheritors having ultimately become absentees, the native Irish of Carlow, King's County, Queen's County, and Westmeath seized on their estates, and obliterated all traces of the English law from the western and some of the midland parts of the province; nor was it till the reign of Elizabeth that the whole was brought again under a regular government. The counties of Louth, Meath, Dublin, Kildare, and Wexford have not shaken off the English law or abjured English manners at any time since the Conquest.

Leinster gives the title of duke to the Fitzgerald family, whose head is the sole duke and premier peer of Ireland.

LEIODON, a genus of fossil reptiles. (Owen.) One species, found in the chalk of Norfolk.

LEIOTRICHANÆ, a sub-family of birds established by Mr. Swainson. Legs large, robust, syndactyle. Hind toe longer than the outer. Wings short and rounded. Bill strong; the gonyes ascending. The only genera are *Leiothrix* and *Pteruthius*. Locality, India.

LEIPOA (*ocellata*), is the name of the Australian native pheasant. It belongs to the gallinaceous family of birds *Megapodidae*. Its habits bear a very close resemblance to those of our own pheasants.

LEIPZIG, one of the four circles of the kingdom of Saxony, is bounded W. and N. by Prussia, E. by the circle of Meissen, and S. by that of the Erzgebirge and the principality of Saxe-Altenburg. Its area is 1342 square miles, and the population in 1861 was 506,492. The country is level, except in the south and south-east, where there are some offsets of the Erzgebirge. The soil is fertile and well cultivated; but the country is deficient in wood, which is procured from the Erzgebirge and the circle of Voigtland. Potter's clay, limestone, marble, porphyry, and jasper are found. The breed of sheep is good, and great numbers are reared. The manufactures consist of woollens, cotton, and linen. The climate is temperate and healthy.

LEIPZIG, the second city in the kingdom of Saxony, and capital of the circle of Leipzig, stands in 51° 20' 16" N. lat., 12° 21' 45" E. long., in an extensive plain watered by the Pleisse, at a distance by railway of 65 miles N.W. from Dresden, and 133 S. by W. from Berlin. The town, including its suburbs, is nearly a mile in length, from N. to S., and three-quarters of a mile in breadth. It was formerly well fortified, but the ramparts have been converted into public walks and gardens. The only remaining part of the fortifications is the castle, called the Pleissenburg, upon which the observatory now stands, in 51° 20' 19" N. lat., 10° 1' 45" E. from Paris. This town is the largest commercial place in East Germany, and is situate on the White Elster, where it is joined by the Pleisse and Parde. The population in 1861 was 78,495, nearly all Protestants.

Leipzig is not regularly built; the streets are generally narrow, though well paved and lighted; but it contains many very handsome parts, numerous

elegant public buildings, private houses resembling palaces, and many seats, with fine gardens, in the suburbs. The most remarkable edifices are—the churches of St. Thomas, St. Nicholas, St. Paul, and St. John; the university buildings; the theatre, and the town-hall, built in 1599; the palace, formerly the residence of the electors and kings of Saxony; the clothmakers' and booksellers' halls, and post-office. The great building called Auerbach's House is, in the time of the fairs, a kind of bazaar, where the finest and most costly articles are exposed for sale. There are numerous excellent schools, academies, and many literary and learned societies; a deaf and dumb institution; orphan and lunatic asylums; an academy of design, painting, and architecture; many museums; a large public library of 80,000 volumes, and 2000 MSS., with a cabinet of 6000 coins and medals, and admirable establishments for the poor. The town has a tribunal of commerce, an exchange, savings bank, a discount bank, &c. There is a considerable trade in American and Russian furs; and the wool fairs, especially that held in June, are very important. Leipzig, though comparatively small, has become one of the most important cities in Europe, owing to its university, its fairs, and its book trade.

The university was founded by the Elector Frederick and his brother William, on the 4th December, 1409, which is the date of the bull of Pope Alexander VI., confirming the foundation. During its whole existence of more than four centuries, it has enjoyed the reputation of being one of the most eminent in Germany. The library consists of 150,000 volumes and above 4000 MSS., and is particularly rich in works on philology, medicine, and divinity. The university has attached to it a museum of natural history and a botanic garden, sixty professors, and seventy private teachers. The average number of students is 800. The *Augusteum* contains a very valuable library.

The origin of Leipzig was a Slavonian village that stood in the fork between the Parde and the Pleisse; this is said to have received its name from the lime-trees growing about it, which are called, in Slavonian, Lip, Lipa, or Lipsk. It is not spoken of as a fortified town till the twelfth century, under Margrave Otho the Rich, who granted it a license to hold two fairs, at Easter and Michaelmas. The first fair at New Year was proclaimed in 1458, and the three fairs were confirmed by the emperor in 1507. These fairs have laid the foundation of the prosperity and wealth of Leipzig. They are attended by a vast concourse of merchants from most countries of Europe and Western Asia, and the value of the manufactured goods of all kinds sold annually is estimated at nearly twenty millions sterling. A wool market is also held here in May. The goods brought to the fairs are chiefly woollen and cotton manufactures, iron and hard-wares, leather, linen, paper, porcelain, silks, hides, furs, glass, drugs, cocoa-nut and palm oils, &c.; large quantities of English soft goods are also sold. There are manufactures of silk and half silken fabrics, hosiery, leather, oil-cloths, playing cards, tobacco, gold and silver articles, snuff, chocolate, starch, soap, liquors, and musical instruments, with numerous engraving, dyeing, and wool-spinning establishments. But the singular concentration of the German book trade in Leipzig has been the main cause of the celebrity and wealth of that city. The first two

booksellers, who were also printers, that settled in Leipzig were Steiger and Boskopf, in 1545. It is now the grand emporium of the book trade of Germany, in which more than 180 houses are engaged, and there are many large type-founding establishments. The importance of the publishing business may be judged from the numbers of orders disposed of at the booksellers' exchange or clearing house. The average of such orders is about 50,000 per diem, or about 15,000,000 a year. The number of works published in Leipzig in 1863 exceeded 10,000. Printing is carried on by thirty-nine firms, employing about 1500 workmen and 350 machines. A natural result of the active printing and bookselling trade is a brisk business in paper, which is valued at not less than 225,000*l.* a year. An annual fair is held for the sale of books, which is attended by purchasers from all parts of Europe. For the transaction of business and settlement of accounts, there is a handsome building called the Booksellers' Common Exchange, which was opened in 1836.

Leipzig communicates by railway with Dresden, Berlin, Magdeburg, Halle, Weimar, and Zwickau. Its elevation is 350 feet above the sea, and the mean temperature of the year 46°·4; winter, 32°; and summer, 60°·3 Fahrenheit.

Leipzig has suffered at different periods from the miseries of war. In September, 1631, the great victory obtained by Gustavus Adolphus over Tilly was fought on its plain; and in 1642 it was besieged by the Swedish general Torstenson. The fearful conflicts of the 16th, 17th, and 18th of October, 1813, in which Napoleon was defeated by the allied armies under Prince Schwartzberg, took place near the town; in the village of Probstheida, which was in the centre of the combat, a colossal cross has been erected to commemorate the terrible battle; and the fiftieth anniversary was commemorated October 19, 1863, by veteran survivors and an immense multitude. In the war between Austria and Prussia, in 1866, Leipzig was occupied by the troops of the latter country.

LEITH, a seaport town and contributory parliamentary borough in Edinburghshire, is situated on the banks of the river Leith (which is crossed by stone and other bridges), at its confluence with the Frith of Forth, about two miles N.E. from the city of Edinburgh, with which it is connected by a broad street called Leith Walk. The omnibuses which pass along this fine road every few minutes, and the accommodation afforded by the Edinburgh and Leith Railway, conduct a great traffic from one town to the other. The houses along the Walk now almost join the two places together. Leith is irregularly built and ill-paved, but contains many handsome houses of recent erection, and the streets have been recently much improved. The principal buildings are—North Leith church, with a spire of 140 feet high, in place of one built in 1496; South Leith church, a fine edifice of the fifteenth century; three other churches; five Free churches; four United Presbyterian churches; two Episcopalian chapels; one Roman Catholic chapel; and three chapels belonging to other denominations; a handsome new court-house; exchange and assembly rooms in the Grecian style, with a large news room; custom-house, built 1812; dock warehouse; baths; public

library of 10,000 volumes; mechanics' subscription library, with 7000 volumes; philharmonic society (1831); barracks at Piershill; nautical school (1853); Dr. Bell's and other schools; Marionville girls' school of industry; Trinity house for shipmasters, founded 1555; Gladstone asylum for incurables (1840) near St. Thomas' church; Hawkfield-house lunatic asylum; Leith hospital, and dispensary; South Leith and North Leith poorhouses. There is also a new corn exchange, a town-hall, a mariners' church, and seven branch banks. Among the charitable institutions not noticed above are—John Watt's hospital, erected in 1862, and a ragged industrial school, built in the same year. Half way to Edinburgh, on Bonnington Road, is the Edinburgh and Leith Cemetery. The port of Leith is superintended by a Board of Commissioners. A tidal harbour has been gradually formed by running out piers of wood and stone across the sands; the E. pier being 3530 feet, and W. 3120 feet long. It has a depth of from 20 to 25 feet at high water. There are six graving docks, one lately finished, 400 feet long, 80 wide, and 25 deep at spring tides. New docks to the eastward of the east pier are also in course of construction, occupying 10½ acres in area; the entrance basin covering over two acres. The length of lock is 350 feet, and the breadth 60 feet. The embankment is 3480 feet long, and incloses an area of 36 acres. The dock will be 1100 feet long by 450 wide, and will have 28½ feet of water at high water of spring tides, or 26½ at low. The amount granted by the Loan Commission for constructing it was 224,000*l.* The contract time ends at the beginning of 1868. Across the Water of Leith and Harbour are a stone bridge, three drawbridges, one of which is for the North British Railway. Leith Fort, ½ mile W. of the Custom-house, is an artillery station. A branch rail unites Leith with the fishing town of Newhaven, and Granton pier, erected by the duke of Buccleuch. The Caledonian Railway Company have also formed a large station at the west end of the old dock on ground reclaimed from the sea. Steamers run from here or Granton to Aberdeen, Alloa, Anstruther, Copenhagen, Danzig, Oporto, Dunkirk, Hamburg, Hull, Kirkwall, London, Newcastle, Pillau, Rotterdam, Stettin, St. Petersburg, Stirling, Thurso, Wick, and Lerwick.

The chief commerce of Leith consists in its colonial and foreign trade, and imports of grain, for which it is the great emporium in Scotland. The other chief imports are wine, oil, flax, and wool. The exports are coal, iron, spirits, ale, paper, linen, &c. It has a considerable shipping trade, and there are also several breweries and distilleries. The manufactures consist principally of glass-making and glass-staining, rope and sail making, artificial manures, candles and soap, sugar, oil-cake, ale, printing ink and printing machinery, preserved provisions, iron shipbuilding, iron founding, and machine making. The Leith flour mills are the most extensive and complete in the country. Fish-curing is an important branch of industry.

The number of vessels which entered and cleared at the port of Leith in 1865 was as follows:—Coastwise, entered, sailing vessels, 708 (43,378 tons); steamers, 475 (198,212 tons); cleared, sailing vessels, 615 (39,326 tons); steamers, 470 (200,361 tons).

From the colonies there arrived 32 vessels (14,639 tons); and cleared for thence, 24 (13,420 tons). From foreign countries the entries were 1792 (360,492 tons), and the clearances 716 (233,127 tons). Total entries from all parts, 3007 (616,721 tons); clearances, 1825 (486,234 tons). The number of vessels registered as belonging to the port in 1866 was 213 (46,674 tons), of which 68 (18,958 tons) were steamers. The customs revenue in 1865 amounted to 429,359*l*.

Leith, in union with Portobello and Musselburgh, returns one member to Parliament. The total registered electors in the district in 1866 was 2672; in the borough of Leith only, within ten of 2000. The population of the parliamentary borough, in 1861, was 33,628. Leith was created a parliamentary borough by the Reform Act of 1832. It is governed by a provost and four bailies, who are also admirals, and other eleven councillors; has a sheriff-substitute court, and is a coast-guard station. It was a port as far back as the eleventh century, and was formerly called Inverleith and Restalrig. In 1838 it was made independent of the city of Edinburgh, to which it had been sold in 1567.

In early times the prosperity of Leith, then considerable, was often checked by warlike conflicts: in 1541 the town was burnt by an English fleet; in 1549 it was taken possession of by the French troops who came to the assistance of Mary of Guise during the contest with the Reformed party. Cromwell repaired its fortifications.

This town was the birthplace of the Rev. George Wishart, and of Hugo Arnot, author of the 'History of Edinburgh.'

LEITRIM, a maritime county of the province of Connaught in Ireland, is bounded N. by the Bay of Donegal and by Donegal county, N.E. by the county of Fermanagh, E. by the county of Cavan, S.E. and S. by the county of Longford, and S.W. and W. by the counties of Roscommon and Sligo, from the former of which it is separated by the river Shannon. It lies between 53° 47' and 54° 27' N. lat., and between 7° 35' and 8° 25' W. long., and extends from N.N.W. to S.S.E. 51¼ miles, varying in breadth from 5½ miles to 21 miles. The area is 613 square miles, or 392,363 acres, of which 249,350 are arable, 115,869 uncultivated, 3396 in plantations, and 23,748 under water. In 1851 the population was 111,915; in 1861 it had decreased to 104,744, of whom 94,006 were Roman Catholics, and 9488 belonged to the Established Church.

The outline of Leitrim is very irregular, being contracted in the centre to little more than the breadth of Lough Allen. The district lying S. and E. of Lough Allen is an irregular parallelogram of about 17 miles by 18. This is to a considerable extent encumbered with narrow and steep ridges of low elevation, and there are many small lakes, of which one of the largest is Lough Rinn, about 2 miles in length by 1½ mile in width. Northward from Lough Rinn extends an open undulating plain, interspersed with numerous lakes and streams as far as the southern extremity of Lough Allen. This district forms part of the great limestone plain of Ireland, and contains some patches of excellent arable land, but is in general more adapted for grazing. The main drainage of the limestone district is S. and W. to the Shannon,

but several considerable streams run E. to the lakes on the border of Cavan. Of the latter the principal is the river Dale. A cluster of lakes, of which the largest are called Lough Scur and St. John's Lough, occupies a tract of about 6 miles in length on the north of this level district, and there are upwards of fifty other lakes, varying in size from a quarter of a mile to a mile in length, scattered throughout the same portion of the county. N.W. from Lough Allen is a low tract, in which the river Bonnet flows. With this exception, the northern part of Leitrim is covered with mountain-groups, of which none of the elevations exceed 2000 feet. Lough Maenean and Lough Melvin extend along the eastern boundary of the county, separating it from Fermanagh, in which they partly lie. They are respectively 3½ and 7½ miles in length, and are pleasingly diversified with wooded islands. The Kilcoo river connects them, and their waters are discharged into the Bay of Donegal, by the Drowes. The river Duff, which separates Leitrim from Sligo, runs into the Bay of Donegal, at the eastern extremity of the coast-line. The shore is for the most part a rocky bluff, with a rough stony beach along the foot of it, and is exposed to the whole swell of the Atlantic.

The climate is raw and damp, particularly in the northern parts of the county, owing to the great extent of moory ground and the vicinity of the Atlantic. In the sheltered valleys, however, particularly in the vicinities of Dromahair and Manorhamilton, where there is a kindly soil (often a deep dark loam, overlying limestone), vegetation is as luxuriant as in most parts of other counties in the same latitude. The surface of Leitrim is now barer of wood than most of the neighbouring counties.

The varieties of surface in Leitrim indicate the internal structure with peculiar precision. The flat-topped mountain groups showing steep escarpments and natural terraces belong to the millstone grit or Lough Allen coal formation. The undulating open country has the floetz limestone for its substratum, and the rough coarse land, when not belonging to the Lough Allen basin, generally consists of sandstone, conglomerate, and wacke. The rocks of the Lough Allen coal district are more analogous to the millstone grit of the north of England than to coal tracts in general. Alternations of shale and sandstone containing beds of coal appear wherever the mountains are of sufficient altitude; for it would seem that such a formation had originally extended over the entire district, and that the absence of those members from the lower mountains has been owing to their removal by some abrading and denuding force. At present they remain only on the summits of Sliev-an-ieran, Lugnaculleagh, Lackagh, and on the highest part of the Munterkenny range; and the occurrence of coal in lumps throughout the sandstone, gravel, and blue-clay hills of the south and south-eastern parts of the county confirms the supposition that a portion of the coal formation has been removed. Where the millstone grit formation terminates, the floetz limestone reappears, and occupies the greater portion of the district watered by the Bonnet and its tributaries. The only primary rock within the county is along the western boundary of the valley of the Lower Bonnet, where the granite and trap formation occurs.

The soil of Leitrim is for the most part stiff, cold, and very retentive of wet, but fertile in the valleys. The best tracts are along the Shannon, the Rinn, and the Bonnet. The crops are corn, potatoes, and flax. Leitrim is, however, more a grazing than an agricultural county. Large quantities of young stock, chiefly horned cattle, are raised on the pasturable plains of the southern district. Agriculture is in a very backward condition. Estates are generally large, tillage farms small, and farmsteads often mere cabins. Average rent of land, 10s. 8d. per acre per annum.

Iron and lead ores are abundant; also coal in Sliev-an-ieran mountain, and on the south side of Lough Allen, where it is raised to some extent.

The county is intersected by a new canal, uniting the Shannon, at Carrick-on-Shannon, with Lough Erne at Ballyconnell.

The extension of the Midland Great Western Railway from Longford to Sligo is open through the southern part of Leitrim, by Newtownforbes, Rooskey, Dromod, Drumsna, and Carrick-on-Shannon, and the railway from Enniskillen to Bundoran and Sligo through the north of this county.

The spinning and weaving of coarse linens for domestic use, is the only branch of manufacture carried on with activity. There are three or four bleach-grounds in the county.

Divisions and Towns.—Leitrim is divided into five baronies and seventeen parishes. It is in the dioceses of Kilmore and Ardagh, and the Connaught Circuit, the assizes being held at Carrick-on-Shannon. The county returns two members to Parliament. The number of parliamentary voters is about 2400. The county is in the Dublin or northern military district, and there are barracks at Carrick-on-Shannon.

Carrick-on-Shannon, the chief town in Leitrim, is 98 miles N.W. from Dublin by the road. It is situated on the west bank of the Shannon, and contains a good court-house, county gaol, church, and Roman Catholic chapel. A small part of the town is in Roscommon, on the opposite bank of the river, across which is a bridge. It was formerly a parliamentary borough, but has been disfranchised. Population, 1587. *Leitrim* is a poor village, 3 miles N. from Carrick-on-Shannon, on the river Shannon, here crossed by a six-arched bridge. Population, 243. *Manorhamilton* is a small market town, about 28 miles N. from Carrick-on-Shannon, situated in a beautiful part of the county, and watered by the Owenmore, a fine mountain stream, which falls into the Bonnet a little below the town. Population, 1167. *Mohill*, a market town, about 10 miles S.E. from Carrick-on-Shannon, is partly in Leitrim and partly in Longford county. The parish covers more than 30,000 acres, having a total population of 10,363. The town has 1123 inhabitants in Leitrim.

History and Antiquities.—Before the coming of the English, Leitrim formed a portion of the territory of Breifne, of which O'Rourke was petty king, and was called Breifne or Brenny O'Rourke, to distinguish it from Brenny O'Reilly, the present county of Cavan. The whole of Brenny O'Rourke is said to have been bestowed by King John de Lacey; the O'Rourkes nevertheless continued to maintain their independence until the reign of Elizabeth, when Leitrim was first reduced to shire ground as a separate county in 1563. There were many disturbances in the county subse-

quently, which were not settled till 1615, when the king's title to the greater part of Leitrim was confirmed, and numerous patents were granted to undertakers by a commission appointed for the purpose of disposing of the estates of the Crown in Leitrim, Longford, and King's county. Again, however, on the breaking out of the rebellion of 1641, the native Irish, headed by Sir Owen O'Rourke, seized all the places of strength in the county, with one or two exceptions. The confiscations which followed on the termination of these wars in 1650 included almost all the lands that had been allowed to remain to the native proprietors under former attainders, and may be said to have extinguished the family of O'Rourke.

The remains of antiquity in Leitrim are not very interesting. There are some ruins of the abbey of Fenagh, celebrated during the early period of Irish church history as a school of divinity. The abbey of Creevelea, near Dromahair, founded by the wife of Owen O'Rourke in 1508, was an extensive pile, of which the principal walls are still standing. The remains of the other religious houses are insignificant. O'Rourke's Hall at Dromahair, Castle Longfield, Cloncarrick Castle, Castle Car, and several others now in ruins, belonged to the O'Rourkes. The strongest and handsomest fortalice, however, in the county is the castle of Manorhamilton, built about 1628 by Sir Frederic Hamilton. It is quoined and corniced with cut stone, and is surrounded by a regular rampart with four bastions.

LEITMERITZ. [BOHEMIA.]

LEIXLIP. [KILDARE.]

LE'LEGES. The Leleges appear, from numerous traditions, to have inhabited the islands of the Ægean Sea and the western coasts of Asia Minor from a very early period. In Homer they are represented as the allies of the Trojans. Strabo informs us that they once inhabited, together with the Carians, the whole of Ionia. But in the numerous traditions respecting them in the north of Greece we find no connection between them and the Carians. According to Aristotle, they inhabited parts of Acarnania, Ætolia, Opuntian Locris, Leucas, and Bœotia.

LELY, SIR PETER (or Peter Vander Faes), was born in 1617, at Soest in Westphalia. He studied under Peter Grebber at Haarlem. He afterwards came to England, and was appointed state-painter to King Charles II. He occasionally painted historical pictures, one of the best of which is a representation of Susannah and the Elders, at Burleigh House. His most celebrated performances are the well-known portraits of the beauties of the Court of King Charles II., preserved at Hampton Court. Lely equally excelled as a crayon painter. He died in England in 1680.

LEMAN, LAKE, *Lemánus Lacus*, *Lake of Geneva*, *Genfersee*, extends in the form of a crescent from east to west between Switzerland and the French department of Haute-Savoie. Its breadth varies greatly, being about 9 miles in the middle, 4 towards the eastern extremity, 3 in its western part opposite Nyon, and 1 mile just before reaching Geneva. This narrow part, which is about 14 miles in length from Nyon to Geneva, is called the Little Lake, and more especially the Lake of Geneva. The greatest length of the lake is about 45 miles. The depth of the Lemán, below the cliffs of Meillerie, on

the coast of Savoy, is nearly 1000 feet; it is 500 feet deep near the castle of Chillon, on the opposite coast, and from 600 to 300 feet in other places. Its surface is 1230 feet above the sea, but in summer it rises sometimes from 6 to 8 feet higher, owing to the melting of the snow in the Alps. The water reflects a bright azure tinge like that of the Mediterranean Sea. The Rhone, coming from the Valais, enters the lake at its south-east extremity, where the waters of the river are muddy-coloured; and it issues out of it again at Geneva at the south-west extremity, where its waters assume a deep blue tinge. The area covered by the lake is about 331 square miles. Its waters are transparent, and contain a great variety of fish; it is never wholly frozen over, and is subject to *seiches*, or risings of from 1 to 4 or 5 feet, which last about twenty-five minutes only. Steamboats introduced in 1823 ply regularly between several points on the shores of the lake, the scenery around which has been always a subject of admiration to travellers.

LEMBERG (*Leopol*), the capital of the kingdom of Galizia, lies in 49° 52' N. lat., 24° 2' E. long., and has a population of over 70,000, about 24,000 of whom are Jews. It is situated in a narrow deep valley, on a small stream called the Peltew, which is dry in summer. The town has greatly improved since it came into the possession of Austria. It contains many handsome buildings, broad straight streets, and lofty houses built of freestone, which, with the cupolas and steeples of the cathedrals and churches, give it an air of grandeur. In 1704 Charles XII. of Sweden took it by storm. It was formerly an important fortress, but the fortifications have been pulled down, and low ramparts erected, which are planted with trees and laid out in public walks. This city is the seat of a Greek and an Armenian archbishop, and has, among its public buildings besides, a Dominican church, council-house, and theatre, a handsome cathedral and eighteen other Roman Catholic churches, an Armenian and a Greek cathedral, a Lutheran chapel, three Jews' synagogues, and nine convents. Besides being the residence of the governor-general, and all the chief military and civil authorities of the kingdom, Lemberg has a university, two gymnasia, two theological seminaries, and numerous charitable institutions. The university was founded in 1784, and has a library of 48,000 volumes; the literary institute has 58,000 volumes, mostly of Slavonic history and literature, 1200 MSS., 15,000 medals, and a collection of paintings and prints. The town has several breweries and distilleries, manufactures of woollens, linens, and jewellery; an important transit trade, and extensive corn and cattle markets. Near it are the baths of Szeκλο and Lubien.

LEMGO. [LIFFE.]

LEMMA (λήμμα, literally 'a thing taken or assumed'), a preparatory proposition borrowed from another subject, or from another part of the same subject, and introduced at the point at which it becomes indispensable.

LEMMING (*Georychus lemmus*), a curious little quadruped, found in the northern regions of Europe and America, and more particularly in Norway, Lapland, and Siberia. It varies in size and colour according to its habitat. In Norway it is nearly as

large as our British water-rat; its colour tawny, streaked with shades of black, and spotted with patches of white all about the under parts, and the sides of the head. In Lapland and Siberia it grows no bigger than a field-mouse, and its different hues are less conspicuously defined. Its head is short, but large, thick, and well furred; eyes and ears small; body thick; limbs, and notably its fore-legs, clumsily thick; on each foot there are five toes, and the fore-claws are strong, compressed, and rather crooked; the tail is very short, thick, cylindrical, and covered with strong hairs disposed like those of a pencil at the tips.

The lemming feeds entirely on vegetable food, and hence in the regions which he haunts man regards him with abhorrence; for in winter these animals assemble in immense numbers, and make long journeys in quest of nourishment, devouring every herb and blade they can discover. At certain epochs, not very well understood, but supposed to be decennial, when they have largely multiplied in their mountain homes, and a consequent scarcity of food obtains, they make the most extraordinary migrations. Descending in troops from the snow-clad heights they collect in the plains, like the divisions of a great army, and then, as if by some understood agreement, march forward in defiance of every obstacle, so that nothing can divert them from their chosen course. They swim across the lakes and rivers that lie in their way, and on arriving at the opposite shore re-form in regular array. In these expeditions myriads are drowned, and myriads fall victims to the attacks of hawks, owls, and weasels; but onward they press, devouring all the vegetation they meet with, until the ground they have passed over looks as if scathed by some destructive conflagration. These migrations invariably foretell very severe weather.

When enraged, the lemmings rise on their hind feet and emit a hoarse barking sound. They breed several times in the year, and produce five or six at a birth. The Hudson's Bay lemming is of an ashen colour, with a tinge of tawny on the back. Its docility is remarkable. It inhabits the regions bordering on the Polar Sea, and is very numerous around Hudson's Bay. Gmelin distinguishes two species, which he names *Mus Hudsonicus* and *Mus aspalax*, or the Siberian lemming. To these Linnæus adds *Mus lemmus*, the Scandinavian lemming. All these species belong to the genus *Rodentia*, and burrow under ground, like the moles, though their fore-feet are better adapted for digging.

Some interesting details respecting their migrations will be found in Forester's and Sir Capel Broke's narratives of travels in Norway and Sweden.

LEMNIAN EARTH is an earthy substance, soft, dull, opaque, yellowish white, and falls to pieces when put into water. It was formerly used in medicine under the name of *Terra Sigillata*. Two-thirds of its weight consist of silica.

LEMNISCATĀ, a curve (first noticed by James Bernoulli) having the form of an 8, but with the upper and lower parts perfectly symmetrical.

LEMNOS, or STALIMENE, one of the northern islands of the Ægean Sea, belonging to Turkey, situated nearly half way between Mount Athos and the entrance of the Dardanelles, and about 22 miles south-west of Imbros. Its area is 160 square miles,

and its population about 10,000, all Greeks, with the exception of the Turkish garrison and governor. The modern Greeks call both the island and the town Stalimene. The surface is mountainous, and there are extinct craters; the western part of the island, which is more fertile than the eastern, produces wine and corn, oil, hemp, and flax, and fruits, but it is deficient in timber trees and in wood for fuel. The principal harbour, called Sant Antonio, in the south-west part of the island, is large and safe. The capital town, Lemnos, is on the western coast, and has a citadel, harbour, and shipbuilding docks, with a population of about 1000.

Lemnos is known, in ancient mythology, as the spot on which Vulcan fell after being hurled down from heaven. The Athenians, led by Miltiades, took Lemnos after their conquest of the Chersonesus. (Herod., vi. 140.) Lemnos had two towns, Hephæstia and Myrina. The present castle is supposed to be on the site of the latter.

LEMOINE, FRANÇOIS, was born at Paris in 1688. He was the pupil of Louis Galloche, and in 1718 he was elected a member of the Royal Academy of Painting. He obtained a great reputation by his painting in oil of the Transfiguration of Christ on the ceiling of the choir of the church of the Jacobins, Rue du Bacq, Paris. In 1724 Lemoine visited Italy, where he remained for a year. After his return to France he was made professor of painting in the Academy, and Louis XV. appointed him in 1736 his principal painter, with a salary of 4100 francs. The first of Lemoine's great works was the cupola of the chapel of the Virgin in St. Sulpice, in fresco, which he commenced in 1729, a work of three years' labour. His masterpiece, however, is the Apotheosis of Hercules, painted in oil on canvas attached to the ceiling of the Salon d'Hercule at Versailles.

After the completion of this great work he was without a rival in France, but he never enjoyed his success. He was naturally of a melancholy temperament, a weakness which the loss of his wife and his constant and intense application aggravated to such a degree that it amounted to a chronic aberration of intellect, and he destroyed himself in one of these nervous fits, June 4, 1737, ten months after the termination of his great work at Versailles, and in the fiftieth year of his age.

LEMON. [CITRUS.]

LEMON ACID. [CITRUS AURANTIUM.]

LEMONADE, a well-known cooling beverage, is made by slicing two lemons, and mixing them with two ounces of white sugar in a quart of boiling water, and allowing the mixture to stand till cold. This is the simplest and commonest form. It is a useful drink for allaying thirst, and is employed as a cooling medicine in some diseases.

LEMON GRASS (*Andropogon schenanthus*), an odoriferous grass, a native of India, Arabia, &c., grows in the West Indies and Australia. Its fragrance is oppressive where the grass abounds, and cattle will not eat it. It grows three or four feet high, and is very coarse. Lemon-grass oil is obtained from it by distillation. This oil is used by perfumers, and as a liniment for rheumatic complaints. Europeans in India make a tonic beverage of the young blades of lemon grass.

LEMONS, ESSENTIAL OIL OF, this well-

known essence is extracted from the little cells visible on the rind of lemons, by submitting raspings of the fruit to pressure. It may also be obtained by distilling the peel with water, but the product is less agreeable, although not so liable to undergo decomposition, owing to the absence of mucilaginous matter. When pure, essential oil of lemons is colourless and limpid; specific gravity, 0·847 at 70° Fahr., boiling point about 145° Fahr.; soluble in all proportions in alcohol or ether. It is used to give an agreeable odour to other medicines, and sometimes taken as a carminative in the dose of two or three drops upon sugar. From its agreeable scent it is often added to lotions and ointments.

LEMURIDÆ, the family of Lemurs (*Les Makis* of the French), constituting the last great group of the *Quadrumanæ*, in Cuvier's 'Règne Animal.'

The characters distinguishing the Lemurs from the Monkeys were founded by Linnæus upon the number of the incisor teeth; but as these characters are negative, their application in a strict sense is impossible. The Lemuridæ resemble the monkeys of the old world in having opposable thumbs on the forehands as well as on the hinder pair; and indeed the thumb of the hinder hands is large, and greatly expanded at the tip. In some species the index finger of the fore hands is abbreviated, and the index finger of the hinder pair is armed with a long, subulate, slightly curved claw (in the *Tarsier* the next also); the other nails are flat. Tail variable. Fur woolly. The molar teeth are tuberculous, the tubercles and depressions of the opposing teeth mutually fitting into each other. Habits arboreal and nocturnal.

Several genera are comprehended under the Lemurine family. Of these the chief are:—

1. *Propithecus* (Bennet). Locality, Madagascar.
2. *Lemur*. Locality, Madagascar.
3. *Lichanotus* (*Indris*). Locality, Madagascar.
4. *Stenops* (*Loris* and *Nycticebus*, Geoff.). Locality, India, Ceylon, Java, Sumatra.
5. *Otolienus* (*Galago*). Locality, Africa.
6. *Cheirogaleus*. Locality, Madagascar.
7. *Microcebus*, or Mouse Lemurs. Locality, Madagascar.
8. *Perodictus* (Bennet). Locality, Sierra Leone.
9. *Tarsius*. Locality, Sumatra.

To these we may add two abnormal genera, viz.—

10. *Cheiromys*. Locality, Madagascar.
11. *Galeopithecus* (Flying Lemurs). Locality, Moluccas.

The genus *Lemur* may be thus described. Head long, muzzle pointed; eyes moderate and oblique; tail long and bushy; mammae two, pectoral; all are natives of Madagascar; arboreal, nocturnal. Their movements are light, sweeping, elegant, and precise. They repose wrapped up in the form of a ball, with the bushy tail twined around them. Their usual voice is a low inward grunt, but they often break forth into an abrupt hoarse roar.

Incisors, 4,	Canines, 1—1,	Molars, 6—6.
4	1—1	6—6.

The first false molar below is stout, and resembles a canine, whence has arisen the idea that it is really a canine, whereas the true canines of the lower jaw

are in close contact with the incisors, and like them are obliquely directed. As examples of this genus we may notice the White-fronted Lemur (*Lemur albifrons*), the Ruffed Lemur (*L. macaco*), the

White-Fronted Lemur (*Lemur albifrons*).

Mongooz Lemur (*L. mongos*). These animals are easily tamed, very gentle, and remarkable for their address and agility.

LENA, River. [SIBERIA.]

LENCLOS, NINON DE, was born in 1616, of a noble family of Touraine. Being remarkably handsome and graceful, she was courted by most of the noblemen and wits about court. She retained her attractions to a very advanced age. Some of her letters to St. Evremont, among the works of that author, and in the 'Letters des Femmes Célèbres,' edited by L. Collin, 1805, are the only authentic memorials of her pen. She died in Paris in 1706.

LENNEP. [DÜSSELDORF.]

LENS (Latin for 'a small bean'), a name given to a glass, or other transparent medium, ground with two spherical surfaces in such manner as is seen in the accompanying Plate. Fig. 2 is plano-convex; fig. 1 is double-convex; when the radii are equal, it is called equi-convex; and when one radius is six times the other it is called a crossed lens; fig. 6 is a meniscus; in every such lens the concave side has the larger radius; fig. 5 is plano-concave; fig. 4 is double concave; fig. 3 is concavo-convex; fig. 7 is a compound lens.

Let the following figure represent the passage of a ray, PQ, of light, parallel to the axis, MF, through a lens, QM: then a number of such rays constituting a cylindrical surface about the same axis will, after refraction, converge to a certain point, as F; and at

a greater distance from the axis a like cylinder of parallel rays will converge to a different point, as A, nearer the lens. If the former cylinder be very near the axis, MF, F is considered as the *focus* of the lens; AF is called the longitudinal aberration of a ray, PQ, and FB its latitudinal aberration.

We shall merely state here the principal formulæ for determining the focal length, MF, of a lens. (Illustrative figures are given in the Plate which accompanies this article.)

To find the focus for parallel rays, let $R = \frac{1}{r}$ = curvature of the surface, there being positive values of r and R . Again, let $D = \frac{1}{QC}$ (fig. 8) =

proximity of the focus of incident rays to the surface, D being regarded as positive when Q lies to the right of C , as in fig. 8, and as negative when to the left, as in fig. 9. Then since $QE = a$, and since a is regarded as positive when Q is to the left of E , we must have (fig. 42) $QE = a$, and $QC = QE + EC = r - a$; so that $D = \frac{1}{r - a}$; $a = \frac{1}{R} - \frac{1}{A}$.

Let also $M = \frac{1}{\mu}$; $F = \frac{1}{CF}$ = power of the surface:

$f = \frac{1}{Cq}$ = proximity of the focus of refracted rays to the surface. The focus for parallel rays on the posterior surface of a sphere falls on that surface, and in any other case (as in figs. 10 and 11) q is given by the proportion, $QE : CE :: EH : Hq$.

Figs. 12 and 13 illustrate the aberration of a system of spherical surfaces. If Q and q (fig. 12) be the *aplanatic foci* of the spherical refracting surface, and if with the centre q and any radius greater than qC when the incident rays diverge from Q , but less if they converge to Q , as we describe a surface, KL or kl , and turn the whole figure about Qq as an axis, the surfaces $CPKL$ or $cpkl$ will generate the aplanatic lens.

To find the foci for oblique rays, let Q and Q' (fig. 14) be the foci of two pencils of convergent rays incident on the spherical surface, CC' , whose centre is E ; draw QEC , $Q'E'C'$, cutting the surface in C and C' , and regarding CEQ as the axis of the pencil, RQ , SQ , TQ , the focus of the refracted rays will be found by taking qQ such as that $\frac{1}{Cq}$ or f shall be equal to $(1 - m)R + mD$, and f' shall be equal to $(1 - m')R + m'D$.

When an oblique pencil of light is incident on any system of spherical surfaces, the focus of refracted rays is found according to fig. 15. Take E' , the centre of the first surface, and let Q' be the focus of incident rays. Join $Q'E'$, and produce it to C' , then will C' be the vertex of the surface corresponding to the pencil whose focus is Q' ; and taking $\frac{1}{C'Q''} =$

$\frac{1 - m'}{C'E'} + \frac{m'}{C'Q'}$, Q will be the focus of the refracted rays. Again, join Q'' and E'' , the centre of the second surface, produce to C'' , and take $\frac{1}{C''Q''} =$

$1 - \frac{m''}{C''E''} + \frac{m''}{C''Q''}$, and Q will be the focus after refraction at the second surface; and so on.

The centre of a lens is a point in its axis where a line joining the extremities of two parallel radii of its two surfaces cuts the axis. Thus, in figs. 16, 17, 18, and 19, $E'A$ and $E''B$ being two parallel

radii, join BA, and produce, if necessary, to x , and x will be the centre.

An inverted image of an object is formed behind a convex lens beyond the focal length, as in fig. 20. Let C be the centre of the lens, Pp, passing through C; the rays cross at C, and the image is inverted subtending the same angle, pCq, at C that the object does before the lens. This is the principle of the common camera obscura (fig. 21), in which the rays from external objects are thrown by an inclined looking-glass downwards, and being received on a convex lens, are brought to their focus on a white horizontal table in a room where no other light is admitted. In fig. 21, P is the object, AB the reflector, BC the lens, and p the image on the table, D. If the lens used to form the image be a concave one, or if a convex reflector be used, as in figs. 22 and 23, the rays, after refraction or reflection, diverge, not from any actual points in which they cross, but from points in which they would cross if produced backwards. There is in this case only a *virtual* image formed, visible to the eye if properly situated.

When two or more lenses are placed close together, in finding the approximate focal distance, uncorrected for the thicknesses, they may be considered as one lens, whose focal distance has a reciprocal equal to the sum of the reciprocals of the focal distances of the component lenses.

LENS, CRYSTALLINE. [EYE.]

LENT (in Latin, *Quadragesima*), a time of mortification, commemorative of the miraculous fasting of our Saviour in the desert; used as a preparation for Easter. The Saxon term was *Lencten*, implying Spring, the season when the day increases in *length*, about the commencement of which this fast usually falls: it is, in fact, the Spring Fast. In the ancient Latin church Lent consisted only of thirty-six days: the four additional days were instituted in the ninth century.

LENTIBULA'CEÆ, a small monopetalous order of exogenous plants, resembling *Scrophulariaceæ*. *Pinguicula* and *Utricularia* are the only genera of this order.

LENTIL. [VICLE.]

LENZINITE, an earthy, soft, whitish, translucent mineral, consisting of silica, alumina, and water. When put into water, it divides into numerous small translucent bits, which, when touched, fall into grains of great hardness.

LEO I., Emperor of Constantinople, born in Thrace of obscure parents, entered the military service, and rose to high rank. At the death of the Emperor Marcianus, in 457, he commanded a body of troops near Selymbria, and was proclaimed emperor by the soldiers. Leo followed the measures of Marcianus against the Eutychians. In concert with Anthemius, emperor of the West, he prepared a numerous fleet for the recovery of Africa, which was occupied by the Vandals. The expedition, however, was defeated. Leo died in January, 474, bequeathing the throne to his grandson Leo, the child of Zeno, the captain of his guards, and Ariadne, Leo's daughter, who died in the following year, aged five years.

LEO III., called Isauricus from the country of his birth, was of humble parentage, and served in the army under Justinian II. Under the reign of Anas-

tasius II. he received the supreme command of the troops of Asia. Anastasius was deposed, but Leo would not acknowledge Theodosius III., who was proclaimed in 716, and marched to Constantinople, when Theodosius resigned the crown to Leo in 717. He defeated the Saracens, who had laid siege to Constantinople; and in 719 Anastasius, who had attempted to resume the crown, was beheaded. It was in this reign that the schism of the Iconoclasts or Image-breakers commenced, by an edict of Leo ordering the immediate removal of all images from churches. This led to great disorders, and in the midst of an unsuccessful struggle both against the Saracens of Asia and against the Italians and the pope, Leo died of the dropsy in the year 741, and was succeeded by his son Constantine.

LEO I. was only a deacon when he was chosen by the clergy and the people of Rome to be their bishop, after the death of Sextus III., in 440, under the reigns of Valentinian III., emperor of the West, and Theodosius II., emperor of the East. Soon after his exaltation he had a controversy with Hilarius, bishop of Arelate, and obtained a rescript from the Emperor Valentinian III. suspending Hilarius from his episcopal office. Leo also induced the emperor to issue, in the year 445, several laws against the Manichæans and other heretics. He assembled a council at Rome in 449, in which he annulled the acts of the council of Ephesus, which had absolved Eutyches. [EUTYCHIANS.] Soon afterwards the Ecumenic council of Chalcedon, in 451, condemned the doctrine of Eutyches, and defined the doctrine concerning the person of Christ. Leo died in 461, and was succeeded by Hilarius I. His writings, especially his Sermons and his Epistles, are useful for the history of the times. Quesnel has given a full account of his life, as well as Maimbourg, 'Histoire du Pontificat de St. Léon le Grand.' The Roman Church numbers him among its saints, and gives him the epithet of Magnus, or 'St. Leo the Great.'

LEO III., a native of Rome, was elected after the death of Adrian I., in 795. The principal event of his pontificate was an attempt made upon his life by a band of armed ruffians (for which the two chief conspirators, Paschal and Campulus, were exiled), and an examination into certain charges brought against him by his enemies, but which they failed in establishing. Leo crowned Charlemagne, who from that time styled himself Augustus, and emperor of the Romans. He died in 816, and was succeeded by Stephen IV.

LEO X., *Giovanni de' Medici*, the second son of Lorenzo the Magnificent, was born in December, 1475. After experiencing some reverses of fortune he was elected pope in March, 1513. He appointed his nephew Lorenzo governor of Florence, which continued during Leo's life to be a dependency of Rome.

Leo found the war renewed in Northern Italy. The French were defeated at Novara, and driven from that country; they then formed an alliance with the Venetians, which he endeavoured to break off.

He reopened the council of the Lateran, which Louis XII. acknowledged. That monarch died in the following year, and his successor, Francis I., among his other titles, assumed that of duke of Milan, which proved the signal for a new Italian war.

The French took possession of Milan, and the contending parties subsequently came to terms. A concordat was agreed upon regulating the appointment to the sees and livings in the French kingdom, which remained in force till the revolution of 1789. A marriage was also agreed upon between Lorenzo, the pope's nephew, and Madeleine de Boulogne, niece of Francis de Bourbon, duke of Vendôme.

In 1516 Leo, under some frivolous pretences, deprived Della Rovere, the nephew of Julius II., of his duchy of Urbino, Pesaro, and Sinigaglia, which he gave to his nephew Lorenzo de' Medici. Soon afterwards a conspiracy to murder the pope was discovered at Rome, and Cardinal Petrucci, who was at the head of it, was hanged. In 1517 the council of the Lateran was finally closed, and in the same year Leo authorized the sale of indulgences in Germany, which was the immediate cause of the Reformation. [LUTHER.]

In 1518 a league of five years was proclaimed by Leo among the Christian princes, to oppose the advance of the Turks, who were threatening Italy.

The alliance of Leo with Francis I. was a hollow one, and the former concluded a secret treaty, offensive and defensive, with Charles V., July 8, 1521, by which it was stipulated that the duchy of Milan was to be taken from the French and given to Francesco Maria Sforza, and Parma and Piacenza to be restored to the pope. These changes were soon effected; but in the midst of the public rejoicings thereupon, Leo fell ill, and died December 1, 1521.

For other popes of this name, see article POPE.

LEO (the Lion), a constellation of the Zodiac, which commemorates the Nemean lion killed by Hercules in the mythology of the Greeks. It is surrounded by Ursa Major, Leo Minor, Cancer, Hydra, Sextans, Virgo, and Coma Berenices. A line drawn through the pole star and the lowest of the four in the Great Bear (or γ) passes through Deneb (or β Leonis); and a line drawn through the bright star Regulus (or α Leonis) of the first magnitude and Deneb passes nearly through Arcturus.

LEO, ALLATIUS. [ALLATIUS.]

LEOCEPH'ALUS (Gr. 'smooth-headed'), a genus of Saurian reptiles, of the family *Aganidae*.

LEO MINOR, a constellation of Hevelius, surrounded by Ursa Major, Lynx, Cancer, and Leo.

LEOMINSTER. [HEREFORDSHIRE.]

LEO'N, the name of a kingdom in Spain, which grew out of the conquests of the Christians from the Moors. The immediate successors of Pelayo were kings of Asturias, and resided at Oviedo. Alfonso the Catholic, from 739 to 757, conquered the towns of Leon, Astorga, Simancas, Zamora, Salamanca, and Ledesma, as well as part of Galicia, all of which were added to the dominions of the Asturian kings. Garcia, son and successor of Alfonso III., about 910 transferred the seat of sovereignty from Oviedo to Leon. Henceforth the Christian kingdom in Northern Spain was called the Kingdom of Leon and Asturias. The male line of the kings of Leon became extinct with Bermudo III. in the year 1037. His sister had married Fernando, king of Castile, who thus united both crowns. But upon Fernando's death, Sancho, one of his sons, had Castile, and Alfonso had Leon and Asturias. The two kingdoms remained distinct, although their crowns were sometimes worn by the

same person, for nearly two centuries, until Fernando III., in 1230, permanently united them, assuming the title of king of Leon and Castilla, which his successors retained.

The territory of the kingdom of Leon is comprised in the basin of the Duoro, between the Asturian mountains on the north, the Sierra de Gata and Sierra de Gredos on the south, which divide the basin of the Duoro from that of the Tagus, Old Castile on the east, and Portugal and Galicia on the west.

LEON, a city of Central America. [NICARAGUA.]

LEO'N, THE PROVINCE OF, is bounded N. by the Asturias, S. by Zamora, E. by Palencia, and W. by Galicia. It is 130 miles in length from E. to W., and about 50 wide from N. to S. The area is 5869 square miles, and the population at the last census was 348,756. The province belongs mainly to the basin of the Duoro, being crossed from N. to S. by the Esla, which rises in the mountains of Valdeburon, on the borders of Asturias, and flows southwards into the province of Zamora, where it enters the Duoro. There is a small part of the province of Leon, west of Astorga, which belongs to the basin of the Miño, being watered by the Sil, a tributary of that river. The surface of Leon is mountainous in the north of the province, where it rises towards the Asturian chain, but it slopes to the south, where it sinks into the plain of the Duoro. The country produces corn, fruit, vegetables, hemp, flax, and wine. Large herds of cattle and flocks of sheep, as well as horses and mules, are reared in this province. The inhabitants are for the most part uneducated and lazy; agriculture is in a very backward state; and everywhere the means of communication are defective. The manufactures are unimportant.

Leon, the capital, an old and somewhat decayed city, is said to have been built by the Roman soldiers of the seventh legion, in the time of Vespasian; it was for more than two centuries the residence of the kings of Christian Spain. Its cathedral, built in the thirteenth century, is one of the finest in Spain, and contains the tombs of the old kings. There are two collegiate churches, San-Marco and San-Ysidro, twelve other churches, and four hospitals. The Plaza Mayor, or principal square, is handsome, and there are other squares adorned with fountains. Leon contains 5720 inhabitants. It is 60 miles S.E. of Oviedo, and 174 miles W.N.W. of Madrid. Linen weaving, stocking knitting, and glove making are the principal branches of industry.

LEONARDO OF PISA, or LEONARDO BONACCI, an Italian mathematician who lived at the commencement of the thirteenth century, was the first person who brought to Europe the knowledge of algebra. His work was never printed, but is preserved at Rome, and is described in Cossali's 'History of Algebra.' He was author of a treatise preserved in the Magliabecchi library at Florence, entitled 'Practica Geographia.'

LEONARD, ST. [VIENNE, HAUTE.]

LEONARD'S ST. [SUSSEX.]

LEO'NIDAS, King of Sparta, commanded the Grecian troops sent to maintain the pass of Thermopylae against the invading army of the Persians under Xerxes, B.C. 480. The force under his command amounted to 4200 men, besides the Opuntian Locri and a thousand Phocians. With these, during

two days' fight, he defended the narrow defile which was the usual passage from Thessaly to the southern parts of Greece. But some renegades discovered a circuitous and unfrequented pass by which a body of the invaders crossed Mount Eta. On receiving intelligence that his position was thus turned, Leonidas dismissed all his soldiers except 300 Spartans, the Thebans, whose fidelity to the common cause was suspected, and the Thespians, 700 in number, who resolved to share the fate and the glory of the Spartans—for the laws of Sparta forbade her citizens to turn their backs upon any odds. Being surrounded and attacked in front and rear, the Spartans and Thespians fell to a man after making vast slaughter: the Thebans asked and received quarter. The corpse of Leonidas was mutilated, and exposed on a cross by Xerxes. A stone lion was afterwards raised on the spot where he fell. The slain were buried where they fell, and their memory was honoured by monumental pillars. Two of the inscriptions ran thus:—'Here four thousand men from Peloponnesus once fought three millions.' 'Stranger, tell the Lacedæmonians that we lie here, obeying their laws.'

This is the account of Herodotus (vii. 202, &c.). Diodorus and Plutarch tell the story somewhat differently.

LEONINE VERSES, a kind of measure much in fashion during the middle ages, which rhymed at the middle and end. It consists properly of the Latin hexameter, or hexameter and pentameter rhymed. The most common structure of the verse is that in which the cæsura on the fifth syllable rhymes with the end of the line: as,

'En Rex Edvardus, debacchans ut Leopardus.'

There is an example of a modern attempt at Leonine verses in Parnell's translation of a passage in the 'Rape of the Lock,' beginning,

'Et nunc dilectum speculum pro more reiectum.'

The classical metre is not essential. We find in the ancient hymns of the Roman Catholic Church the rhythm of modern versification; and in the famous song of Walter de Mapes, archdeacon of Oxford in the time of Henry II.:

'Mibi est propositum in taberna mori,
Vinum sit appositum morientis ori,
Ut dicant, cum venerint Angelorum chori,
Deus sit propitius huic potatori.'

Leonine verses were so named after Leoninus, a canon of the church of St. Victor, in Paris, about the middle of the twelfth century; or, as others say, after Pope Leo II., who was a lover and improver of music.

LEONTODON TARAXACUM (*Dandelion*), a perennial herbaceous plant of frequent occurrence. The root, leaves, and flower-stem (scape) contain much milky juice; but the root only is employed in medicine. The leaves by blanching can be rendered fit for use as a salad, as they then retain only a moderate degree of bitterness.

LEONURUS (from *λέων*, 'a lion,' and *οὐρά*, 'a tail'), a genus of plants belonging to the natural order *Labiatae*. *L. cardiaca*, Motherwort, is a bitter herb with a pungent unpleasant smell. It is found in hedges and waste places in Great Britain, all over Europe, and in the middle of Asia. There are eight species of *Leonurus* described by botanists as growing

chiefly in Europe and in the north of Asia. None of them are very ornamental, and being biennial plants, the seeds only require to be sown in the open ground.

LEOPARD'S BANE. [ARNICA.]

LEOPARDS, a name by which the greater spotted feline animals are popularly known. These animals, though less in size than the lion and tiger, are larger than the lynxes and tiger-cats; they are very formidable, active, and daring, and ascend trees with the utmost facility. The group is principally confined to the old world, one species only being American.

1. The Panther and Leopard (*Felis Pardus* and *Felis Leopardus*).—It is difficult to say what positive distinctions exist between the panther and leopard. In both we observe rosettes, or even simple spots on a fine yellow ground; but in the size and minor arrangement of the open rosettes there is the greatest variation. The leopard has been described as differing from the panther in being of a paler yellowish colour, of rather smaller size, and with the rosettes made up of several dots partially united into a circular figure in some instances, and into a quadrangular, triangular, or less determinate form in others. But on these very grounds, if there be two species, there must be several more. Once or twice black leopards or panthers (whichever they be) will be found, in which the ground colour is dull black, with spots of a rich glossy black; and Pennant ('Hist. Quad.') figures a black leopard in the Tower of London, brought from Bengal by Warren Hastings. Some consider this animal to be a distinct species, and describe it under the title of *Felis melas*. In certain parts of Java, according to Péron, the black leopard is common.

Mr. Bennet says, 'Whether the leopard and the panther are in reality distinct species, and if so, on what particular characters the specific distinction depends, are questions that have been so variously solved by writers of the highest eminence, that we cannot, without better opportunities for comparison of specimens than we at present possess, adopt the

Leopard (*Felis leopardus*).

conclusions to which any one of them has come upon the subject.' The fact is this: Suppose it be proved that there are several species of old world *Felidae* entitled to the names of panther or leopard, how can we tell to which the specific title of *Pardus* and *Leopardus* is applicable? On this point we might waste pages by references to writers whose conclusions end in nothing. The leopard or panther is found in Africa, India, and the Indian Islands, as Ceylon, Sumatra, Java, &c.

2. The Rimau Dahau (*Felis macrocelis*, Temm.).—a beautiful species, with bold square or angular markings; a native of Sumatra, and discovered there by Sir Stamford Raffles. This form leads the way to the tiger-cats, with marbled markings.

3. The Ounce (*Felis uncia*).—Till recently the Ounce (*Ounce*, Buffon) was confounded either with the leopard or the panther, but it is a decidedly distinct species. Buffon has figured it, and Bewick has copied the figure.

In 1837 Dr. Gray brought before the notice of a meeting of the Zoological Society of London some mammalia which he had lately purchased for the British Museum from a collection made by the late Colonel Cobb in India, among which was an adult specimen of the *Ounce* of Buffon ('Hist. Nat.'). on which Schreber formed his *Felis uncia*, which has been regarded by Cuvier, Temminck, and most succeeding authors, as a leopard, but which, continued Dr. Gray, 'is a distinct species, easily known by the thickness of its fur, the paleness of its colour, the irregular form of the spots, and especially by the great length and thickness of the tail.' Dr. Gray observed that a more detailed description of this animal was unnecessary, as it agreed in all particulars with the specimen described by Buffon.

4. The Cheetah, or Hunting Leopard (*Felis jubata*, Schreber, *Cynailurus jubatus*, Wagler).—The Cheetah, or Chetah, is a slender but tall animal, with wiry limbs, and with claws but slightly retractile. It is extensively spread through Africa and the warmer parts of Asia, and in India and Persia it is domesticated and trained to the chase or rather the surprisal of the antelope, towards which it creeps stealthily until within range of its spring. The general colour of the cheetah is fawn yellow, variegated with round black spots; a distinct black stripe passes from the inner angle of the eye to the angle of the mouth; the tip of the nose is black. The profile of the forehead and face is convex; the eye is peculiarly large, fine, and expressive; the pupils are circular. The tail is long and curled up at its extremity, which is white. The fur is rather crisp, and on the neck and shoulders is longer than elsewhere, and forms a sort of mane.

5. The Jaguar or American Panther (*Felis onca* of Linnæus).—This formidable animal is larger, and more robust and stoutly made, than the leopard. The head is larger and rather shorter, and the profile of the forehead more prominent; the limbs are more thick and muscular, and the tail shorter. Specimens of this savage beast have been confounded with the leopard; but the Jaguar, besides differing in other points, always displays a bold streak or two of black extending across the chest from shoulder to shoulder. The rosettes on the body are very large, open, and somewhat angular, with a central spot or two of black in each; a chain of black dashes extends along the spine.

Of all the American *Felidæ* the jaguar is the most formidable. It prefers the wooded and marshy districts of the warmer regions, and is common in Paraguay and Brazil. According to Humboldt 4000 of these beasts are annually killed in the Spanish territories, and 2000 skins are exported every year from Buenos Ayres only. The jaguar climbs with the utmost ease, and chases the monkeys among the

branches. It also swims well, crossing broad rivers with ease. Birds, fish, turtles, peccaries, capybaras, monkeys, and domestic quadrupeds are its prey, but it seldom voluntarily attacks man: when hard pressed, however, it makes a resolute defence.

There is a black variety of the jaguar, *Le Jaguar Noir* of the French, *Felis nigra* of Erxleben, and probably the *Jaguarete* of Marcgrave.

The *Chati*, the *Ocelots*, and other *Tiger-cats*, are noticed under the article **TIGERS**. The *Puma* is described under the article **LION**.

LEOPOLD I., Emperor of Germany, of the house of Austria, son of Ferdinand III. and of Mary Anne of Spain, born in 1640, was proclaimed king of Hungary in 1655, king of Bohemia in 1657, and emperor of Germany in 1659. The Turks, who were then overrunning Hungary, were joined by a large portion of the Hungarians under Emeric Tekeli, and gained several victories over the emperor. Louis XIV., who had encouraged the Turks in their invasion, now formed a plot, by means of his diplomatic agent at Cracow, to dethrone Sobieski, who had promised to assist Leopold. The plot, however, was discovered by means of an intercepted letter written by the French ambassador. Sobieski laid the matter before the Polish diet, expressing at the same time his conviction, whether real or politically assumed, that the whole was a fabrication. 'But,' added he, 'let us convince the world also that it is an imposture; let us declare war against the infidels.' The declaration was voted almost unanimously. On September 11, 1683, the allied army reached the summit of the Calenberg, which commanded a view of the Austrian capital, then invested by the Turks. On the 12th the battle was fought, the Turks were defeated, and Vienna and perhaps all eastern Europe were saved.

At the diet of Presburg of 1687 the crown of Hungary was declared to be no longer elective, but hereditary in the Austrian male line. Transylvania likewise submitted to Leopold. The Turkish war was at length concluded by a great victory gained by Prince Eugene, in September 1697, near Zenta in Hungary, which was followed by the peace of Carlowitz.

Leopold sustained three wars commenced by Louis XIV. The first was ended by the treaty of Nymuegen in 1679, and the second by the peace of Ryswick, in 1697. The third was that of the Spanish Succession, to which Leopold's son, the Archduke Charles, had undoubted claims. Leopold, however, did not live to see the termination of it; he died in 1705.

The principal internal events in Germany during the reign of Leopold are—1. The establishment of a ninth electorate in favour of Ernest Augustus, duke of Brunswick Lüneburg, who in 1692 became the first elector of Hanover. 2. The assumption of the regal title by Frederic, elector of Brandenburg and duke of Prussia, in 1701. 3. The establishment of a permanent Diet, attended, not by the electors in person, but by their representatives. Leopold's private character was estimable, and his disposition was good and well-meaning, but he was weak, irresolute, and inclined to bigotry. He was succeeded by his eldest son, Joseph I.

LEOPOLD II. of Germany, and I. of Tuscany, was the second son of Maria Theresa of Austria and Francis of Lorraine. He succeeded to the Grand

Duchy of Tuscany in 1765, and fixed his residence at Florence. During the five-and-twenty years of his administration he greatly improved the condition of Tuscany. By his own absolute act, in 1786, he promulgated a new criminal code, abolished torture and the punishment of death, and established penitentiaries to reclaim offenders. He finally abolished the Inquisition in Tuscany in July, 1782, and placed the monks and nuns of his dominions under the jurisdiction of the respective bishops. This he effected through the agency of Ricci, bishop of Pistoia. A curious controversy followed with the court of Rome. In his civil administration Leopold effected many important reforms.

By the death of his brother Joseph II., February 20, 1790, Leopold succeeded to his dominions, and was elected emperor of Germany, whilst his son Ferdinand succeeded him as grand duke of Tuscany. On assuming the administration of the hereditary dominions of the house of Austria, Leopold showed an earnest desire to please his subjects, and he succeeded; he abolished the more obnoxious innovations of his brother; he concluded a peace with the Porte; he pacified Hungary; and having done this, his next step was to endeavour to pacify the revolted states of the Netherlands, by offering to re-establish their ancient constitutions. The insurgents having obstinately refused to listen to his offers, he sent troops against them, and recovered without much difficulty those fine provinces. Then came anxieties concerning the fate of his sister Antoinette, queen of France, and her husband; the convention of Reichenbach, and that of Pilnitz, in August, 1791, between Austria and Prussia, for the purpose of checking the progress of French revolutionary proselytism. But the intentions of Leopold were essentially pacific. In the midst of all these cares Leopold died, March 1st, 1792, aged forty-four. He was succeeded by his eldest son, Francis II.

LEOPOLD I., GEORGE CHRISTIAN FRIEDRICH, King of the Belgians, was born on December 16, 1790. He was the youngest son of the late Duke Francis of Saxe-Coburg, and brother of the late Duke Ernest, and also of the duchess of Kent. He was consequently uncle both of the late Prince Consort and Queen Victoria. He was most carefully educated, having the reputation of being one of the best informed princes of Europe. His sister having married the Grand Duke Constantine, he entered the Russian military service with the rank of general, and in that capacity accompanied the Emperor Alexander to Erfurt. The menaces of Napoleon forced him to resign his commission for a time, but he afterwards re-entered the service, and distinguished himself at the battles of Lutzen, Bautzen, Leipzig, and Culm. He visited London in 1815, and out-rivalled the prince of Orange as suitor for the Princess Charlotte, daughter of George IV., and heirress to the throne. A settlement of 50,000*l.* per annum was made upon him, and he was naturalized and created Duke of Kendal and a field-marshal. The marriage was celebrated on the 2nd of May, 1816, and on the 5th of November in the following year the princess died in childbirth. For many years after this melancholy event Prince Leopold lived a very quiet and retired life, residing principally at London and Claremont. In 1830 he was offered the crown

of Greece, but finally declined it in consequence of the dissatisfaction which the Greeks felt at the arrangements which had been made on their behalf by the three great powers—England, France, and Russia. About this time Belgium threw off the yoke of Holland, and in June, 1831, he was elected king of that country by a national congress. Both externally and internally the new monarch had great difficulties to confront, as Holland refused to accept the settlement of Belgium acknowledged by the other European powers, and Leopold once more took the field at the head of a portion of the Belgian army. In 1832 he married Louise, the daughter of Louis Philippe, king of the French, and thus secured an alliance with his most powerful neighbour; but it was not until 1838 that the differences between Holland and Belgium, as to certain territories, were finally and amicably settled. The treaty of separation was signed April 19, 1839. For many years it required all his majesty's great ability to deal with the internal affairs of his kingdom, more especially with the 'religious difficulty,' he being himself the Protestant sovereign of a Catholic country, and there being endless controversies between the liberals and the extreme church party. But whatever his private feelings might have been, Leopold always acted as a thoroughly constitutional king, and endeavoured to govern according to the wishes of the parliamentary majority, of whatever political or religious sect. In the revolutionary year of 1848 he assembled the leaders of the chief political parties, and reminding them that as he had accepted the crown solely at the desire of the Belgian people, so he was equally ready to relinquish it if it was their general wish that their country should become a republic. This dignified offer was declined, and the revolutionary bands who appeared on the Belgian frontier from France were quickly repulsed. His queen died in 1850. She had borne him three children, Leopold II., the present king, and another son and a daughter. On many occasions subsequent to the death of his wife King Leopold had attacks of severe and painful illness, and underwent more than one medical operation. His death finally took place at his palace of Lacken, December 10, 1865. During his reign he effected much for the internal prosperity of his kingdom, especially in the establishment of an extensive system of railways, and a national bank. His commercial policy with foreign countries was also exceedingly liberal; and in fact he always conducted himself with prudence, firmness, and moderation, with continual regard to the principles of the Belgian constitution, and with an evident desire to do everything in his power to promote the welfare and happiness of his people, by whom he was very much beloved. During the latter years of his life he was the confidential adviser of several European sovereigns, but more especially of her majesty Queen Victoria. On accepting the throne of Belgium he surrendered his pension from England, on the sole condition that the British government should undertake the expense of keeping up Claremont.

LEPADITES (Gr. *λαπάς*, 'a limpet'), the Goose Barnacles, of the family *Cirripedes*, of which *Lepas* (Barnacle) is one of the genera.

LEPANTO, GULF OF, the ancient Corinthian Gulf, is a narrow sea above 70 miles in length from

west to east, extending between the northern coast of the Peloponnesus and the mainland of Greece. It is entered from the Gulf of Patras on the western side by the Strait of Lepanto, not quite two miles wide, which is defended by two castles. A few miles inside of the straits, on the northern coast, is the town of *Lepanto*, the ancient *Naupactos*, built on a hill, and commanded by a castle, with a good harbour and between 2000 and 3000 inhabitants. The gulf widens towards the middle to the breadth of 12 or 13 miles, exclusive of several deep bays which indent its northern coast, especially the Bay of Salona, the ancient Crissæan Gulf, which stretches about 8 miles to the north. The eastern extremity of the Gulf of Lepanto terminates in two bays; that of Corinth to the south-east, where the Lechaum or western harbour of Corinth once was; and the other, which extends to the north-east, bordering on the territory of Mégaris and stretching to the foot of Mount Cithæron. This last bay is now called Livadostro.

Lepanto has given its name to a celebrated naval battle fought on the 7th October, 1571, in which the Christian allied fleet, amounting to 210 ships in all, commanded by John of Austria, utterly defeated the Turkish fleet of 300 sail under Ali Pasha, who lost his life in the engagement. Cervantes fought in this battle, and received a wound which deprived him of the use of his left hand for the rest of his life. The battle of Lepanto is called by some Italian writers the battle of Curzolari, from the group of islets so called at the mouth of the Achelous, where the battle commenced.

LEPEDOLITE, *Lilac Mica*, occurs massive, and is usually composed of small flexible thin scales. The colour varies. Before the blow-pipe it melts into a spongy semi-transparent white globule. It consists mainly of silica and alumina.

LEPER, a person affected with leprosy, a scaly cutaneous disease very general in the East. Lepers are frequently mentioned in the Old Testament. By the Jewish law they were excluded from all society, and driven into uninhabited places. Even kings, when afflicted with the disease, were shut out of their palaces, and deprived of their sovereign power. When a leper was cured he appeared at the city gate; but was not allowed to enter until examined by the priest, and had undergone certain ceremonies and ablutions. The disease is supposed to have originated from the poor living so much on fish, and wearing dirty under-garments. It seems to have disappeared, as it is supposed, with the use of tea, and the wearing of linen next the skin.

LEPIDIUM (from *lepis*, 'a scale,' in allusion to the form of the pods, which resemble little scales), a genus of plants belonging to the natural order *Cruciferae*. *L. sativum* is the common Garden Cress. It is a native of Persia and the island of Cyprus in corn-fields. There are three varieties of the species; the broad-leaved cress, which is cultivated chiefly for rearing young turkeys; the curled variety, which is sometimes used as a salad, but is considered preferable as a garnish; and the common plain-leaved cress, which forms one of our earliest spring salads, and has a peculiarly warm and grateful relish. All the varieties are raised from seed, of which one ounce will serve for a bed four feet square.

L. latifolium is a native of Europe, also of Algiers,

and of several parts of England, generally near the sea. It has a very hot biting taste, and has been used instead of horse-radish. Poor people are in the habit of eating it as a condiment to their food, hence it has acquired the name of Poor Man's Pepper.

LEPIDODENDRON, an important genus of fossil plants, in the examination of which Sternberg, Brongniart, and Lindley have signalized their abilities, not without success, though some uncertainty yet attaches to the botanical relations of these singular specimens of the flora of earlier nature. M. Brongniart referred the *Lepidodendra* to the natural group of *Lycopodiaceæ*, pointing out, however, their analogies to *Cycadææ* and *Coniferæ*.

Dr. Lindley, in the first volume of the 'Fossil Flora of Great Britain,' after discussing the botanical relations of *Lepidodendra*, remarks, 'On the whole, we are led to conclude that the *Lepidodendron* genus was not exactly like either *Coniferæ* or *Lycopodiaceæ*, but that it occupied an intermediate station between these two orders, approaching more nearly to the latter than the former.' These views have since been confirmed by later discoveries. The species are numerous, and confined to the older strata, and specially abundant in the coal formation. [COAL PLANTS.]

LEPIDOPHYLLUM. Fossil leaves which occur in the coal formation are thus named by M. Brongniart. Some of these belong to *Lepidodendron*, others to *Stigmara*.

LEPIDOPTERA, one of the orders into which insects are divided, called *Glossata* by Fabricius.

This order is composed of those insects which are commonly known by the names of Butterflies and Moths, and which possess four wings, usually of large size, and covered with a multitude of minute scales, which to the naked eye appear like powder. The nervures of the wings are not very numerous, and are disposed chiefly in a longitudinal direction; a small tippet-like appendage is situated on each side of the thorax at the base of the wings, which appendages are called by Latreille *pterygoda*. The antennæ are almost always distinct, and are composed of numerous minute joints. The parts of the mouth are formed into a proboscis fitted for extracting the nectar from flowers, or conveying other juices to the oesophagus. This proboscis, when not in use, lies spirally folded beneath the head and between two palpi covered with hair, which are usually directed forwards and upwards, and which represent the labia palpi. The proboscis is called, in these insects, *anthia* by Messrs. Kirby and Spence, *spitrontrape* by Latreille, and *lingua* according to the nomenclature of Fabricius, and is composed of two subcylindrical tubes, which vary greatly in length in the different species of lepidopterous insects, and between which there is an intermediate one, formed by their junction, which is effected by means of a series of hooks inosculating one with another like the laminae of a feather. It is through this central tube that the juices are conveyed, the lateral tubes being intended, as it is supposed, for the reception of air; they are called by Messrs. Kirby and Spence *solenaria*, a name, however, which is not wanted, since the two tubes in question represent the maxillæ, and are furnished with minute maxillary palpi at their base. The mandibles and labrum in these insects are

reduced to mere rudiments. The head, thorax, and abdomen are always more or less covered with hair; the former, besides the ordinary compound eyes, is sometimes furnished with simple eyes or stemmata; these, however, are generally hidden by the hair of the head, and do not exist in the diurnal lepidoptera.

The food of the larvæ almost always consists of vegetable substances, generally the leaves of plants. Some live in rotten or rather dead wood, upon which they feed; others feed upon animal substances, and are very destructive to furs, woollen goods, feathers, &c.; and the larva of a species of moth (the Honeycomb moth, *Galleria cereana*) subsists upon wax, living in bee-hives. This larva forms galleries in the honeycomb, which are invariably inclosed by a strong silken web, serving to protect it from the bees; and as the moths increase rapidly in number, the hive is of necessity soon deserted by its proper inhabitants.

The pupæ, or chrysalises, are incapable of eating or locomotion, and are termed obtected; they usually approach somewhat to an oval form, but are pointed more or less at the posterior extremity. The shape of the pupæ, however, varies much according to the species; and those of butterflies often present numerous angular projections, and sometimes exhibit brilliant metallic colours. The parts of the perfect insect, such as the head, thorax, segments of the abdomen, wings, and legs, can be distinctly traced.

Latreille divides this order into three principal groups, according with the three Linnæan genera *Papilio*, *Sphinx*, and *Phalæna*. To this first group he applies the name *Diurna*; *Crepuscularia* is used to designate the second; and the third group, or that corresponding to *Phalæna* of Linnæus, is called by Latreille *Nocturna*.

In the accompanying Plate various species of Lepidoptera and Hemiptera are figured. Figs. 1, 2, 3, and 4, belong to the *Heliconidæ*, a family of Lepidopterous insects belonging to tropical regions; the other figures represent varieties of the HEMIPTERA, which see.

LEPIDOSIREN, or Mud Eel, a genus of animals, two species of which have been met with, namely, *Lepidosiren paradoxa* and *L. annectans*. There was for a considerable time much controversy among naturalists as to the true place of this form in the zoological scale. Should it be ranged with the class fishes, or with amphibious reptiles? Professor Owen has ever held that its true place is among the fishes, and Dr. Gray has as earnestly pleaded for its classification among the *Amphibia*. It is now regarded by most zoologists as having its proper place among fishes. There are, however, many characteristic features which make it look almost like a transitional link between fishes and amphibia. The leading features of its organization are these: the body is round, compressed posteriorly, and surrounded by dorsal and anal fins; the skeleton is partly of cartilage and partly of bone; the pectoral and ventral fins resemble flexible cirrhi; the body is covered with cycloid scales invested with an epidermis. It has two small conical teeth which are movable in the intermaxillary bone, and two large ones folded longitudinally in the margin of each jaw. The internal structure likewise presents many points intermediate between fish and reptile.

LEPIDO'STROBUS. M. Brongniart gave this name to the Fossil Fruits, supposed to be those of the *Lepidodendra*, which frequently occur in the coal formation.

LEPIDUS, MARCUS ÆMILIUS, a celebrated Roman triumvir, was elected ædile of Rome B.C. 52, and prætor B.C. 49, in which year Cæsar came to an open rupture with the senatorian party. [CÆSAR; ANTONIUS.] From his entrance into public life he opposed the senatorian party; and his great riches and family connections made him an important accession to the popular cause. On the first expedition of Cæsar into Spain, Lepidus was left in charge of the city. During Cæsar's absence, Lepidus proposed the law by which that great general was created Dictator.

After the death of Cæsar, Lepidus was courted by both parties. Lepidus promised to assist the Senate, but at the same time carried on a secret negotiation with Antonius; and when ordered by the Senate to join Decimus Brutus, instead of obeying, he united his forces with those of Cæsar's successor.

In the autumn of this year, B.C. 43, the celebrated triumvirate was established between Antonius, Lepidus, and Octavianus (Augustus); and in the division of the provinces, Lepidus received Spain and Gallia Narbonensis. The conduct of the war against Brutus and Cassius was assigned to Antonius and Augustus; while the charge of the city was intrusted to Lepidus, who was again elected consul (B.C. 43). After the defeat of Brutus and Cassius, in the new division of the provinces which was made after the battle of Philippi, Spain and Gallia Narbonensis were taken from Lepidus, and Africa given to him instead. Lepidus had now lost all authority; but he was again included in the triumvirate, when it was renewed B.C. 37. In the following year he was summoned from Africa to assist Augustus in Sicily against Sextus Pompeius; and he landed with a large army, by means of which he endeavoured to regain his lost power. But being deserted by his own troops, he was obliged to implore the mercy of Augustus, who spared his life, and allowed him to retain his private property and the dignity of pontifex maximus, though he banished him, according to Suetonius, to Circæi ('Octav.' c. 16). Lepidus died B.C. 12.

LEPONTIAN ALPS. [ALPS.]

LEPORIDÆ, a family of Rodents, the type of which may be considered as existing in the common Hare.

Cuvier characterizes the Hares as having the upper incisor teeth double, that is to say, each of them has, behind, another smaller one. Their molars, to the number of five, are formed each of two vertical laminæ soldered together. In the upper jaw there is a sixth, which is simple and very small. They have five toes before and four behind, an enormous *cæcum* five or six times larger than the stomach, and furnished within with a spiral lamina, which runs throughout its length. The interior of their mouth and the bottom of their feet are furnished with hair, like the rest of their body. He divides the group into—

1. The Hares, properly so called, which have long ears, a short tail, the hind-feet much longer than the fore-feet, imperfect clavicles, and the suborbital space in the skeleton pierced like net-work. The species

are, he observes, rather numerous, and so much alike that it is difficult to define them.

The common Hare, *Lepus timidus*, which is generally considered as the type, is too well known to need description, and it will suffice to state that it is the *Lagos* (*Lagus*) of the Greeks; *Lepus* of the ancient Italians; *Lepre* and *Lievora* of the modern Italians; *Liebre* and *Lebratillo* of the Spaniards; *Lièvre* of the French; *Has*, *Haas*, and *Hase* of the Germans; *Maukin* of the Scotch.

We must here notice the Irish Hare, *Lepus Hibernicus*, which Mr. Jenyns considers a variety of *Lepus timidus*; but Mr. Bell ('British Quadrupeds') states that a careful examination of several specimens has assured him that it is not merely a variety of the common Hare of England, but that it is specifically distinct. It further appears that *Lepus Hibernicus* is the only Hare found in Ireland, which may account for its remaining so long unnoticed; for opportunities of comparison could not have been very frequent. Its fur is considered valueless.

The Varying Hare, or Alpine Hare, *Lepus variabilis* of Pallas, which changes the colour of its coat with the seasons, requires a short notice. The fur, which is full and soft, is in summer gray, intermixed with silky hair of a yellowish brown; the ears are tipped with black, and the under parts are light gray. The tail is white beneath and gray above. As the winter approaches, the fur gradually becomes white, except that on the lips and the tips of the ears, which remains black.

The Rabbit, or Coney, *Lepus cuniculus*, Linn., *Coniglio*, of the Italians, *Conejo* of the Spanish, *Kaninchin* of the German, is known to every one.

2. *Lagomys*. The species composing this division have the ears moderate, the legs not much differing from each other, nearly perfect clavicles, and no tail: they have hitherto, he adds, been only found recent in Siberia, and fossil remains of an unknown species have been detected in the osseous breccia of Corsica.

In the genus *Lagomys* the muzzle is acute; the ears short and somewhat rounded; the soles of the feet hairy; the claws falcular; no tail. Locality, Northern Asia.

• Example.—*Lagomys pusillus*. This species

Calling Hare (*Lagomys pusillus*).

(*Lepus pusillus* of Pallas; Calling Hare of Pennant) has the head longer than is usual with Hares, and thickly covered with fur, even to the tip of the nose; numerous hairs in the whiskers; ears large and rounded; legs very short; soles furred beneath; its

whole coat very soft, long, and smooth, with a thick long fine down beneath, of a brownish lead colour; the hairs of the same colour, towards the ends of a light gray, and tipped with black; the lower part of the body hoary; the sides and ends of the fur yellowish. Length about six inches; weight from $3\frac{1}{4}$ to $4\frac{1}{2}$ ounces; in winter scarcely $2\frac{1}{2}$ ounces.

Localities.—The south-east parts of Russia, and about all the ridge spreading from the Ural chain to the south, about the Irish, and in the west part of the Altaic chain, but nowhere in the East beyond the Oby.

Habits.—Delighting in the most sunny valleys and hills, where the herbage is plentiful and delicate, the Calling Hares choose those localities, when in the vicinity of a wood, which will afford them a ready refuge in the case of danger or alarm. Their burrows, especially those belonging to the old ones and to females, are curious and intricate, so well concealed amid the shrubs of some dry spot that detection is very difficult; and to increase the difficulty, the animal is said to drop its excrements under some bush, that they may not betray its abode, which would almost defy search, were it not for their peculiar cry or call; this is described as being like the piping of a quail, but deeper, and so loud as to be heard at the distance of half a German mile. It is repeated at just intervals, thrice, four times, and even six, at night and morning, but seldom in the day, unless the weather be cloudy. Both the male and female emit this note, but the latter is silent for some time after she has given birth (in May) to her young, which are born naked and blind, and are carefully attended to by the mother, who covers them up warm with the cosy materials of her nest.

LEPRA (the Greek word *λεπρα*, 'scaliness'), an affection of the skin. It is characterized by an eruption of circular spots of inflamed skin covered with scales, varying from the size of a pin's head to that of a shilling or even a half-crown piece, occasionally mixed with large irregular patches formed by the coalescing of the borders of several contiguous spots. The whole is surrounded by a slight aureola of redness. In the early stage of the disease, and in the small spots, the inflamed skin, which is slightly raised above the surrounding parts, possesses only a thin scaly covering; and in the larger patches, formed by the coalescence of several spots, the characteristic appearances become somewhat confused; still, on careful examination, the elevated margin, circular outline, and central free spot may more or less be recognized.

It is generally tedious of cure, recurring periodically in some constitutions, whilst in others it will continue for two or three years. Most frequently it arises without any assignable cause; but occasionally it has appeared to be dependent upon suddenly suppressed cutaneous transpiration in consequence of drinking cold water when over-heated. For a careful examination of the various forms of leprosy mentioned in the Bible, see *Biblical Natural Science*, by Dr. Duns. (Mackenzie.)

LEPROSY. [LEPRA.]

LEPTACANTHUS, a genus of fossil placoid fishes, occurring in the carboniferous and oolitic strata. (Agassiz.)

LEPTÆNA, a subdivision of the great family of

fossil *Brachiopoda*, proposed by Dalman to include species which Mr. Sowerby named *Producta*. Its use is at present more restricted, and has become rather indefinite. *Leptæna lata* of the Silurian system may be regarded as a frequent type. The species are extinct, and are confined to palæozoic strata.

LEPTIDES, a sub-family of dipterous insects of the family *Brachystoma* (Macquart). The family of insects to which the present section belongs is distinguished by the proboscis being short and membranous; the lips terminal and thick; third joint of the antennæ simple, often spatulate; stylet often dorsal; abdomen usually with five distinct segments. The wings have commonly one submarginal and three posterior cells. The family *Brachystoma* is divided by Macquart into four tribes or sub-families—*Xylotomæ*, *Leptides*, *Dolichopoda* and *Syrphidæ*. The first, or the *Xylotomæ*, are distinguished by the third joint of the antennæ being conical, by the wing having two submarginal cells, and by the tarsi being furnished with two small cushions. In the sub-family *Leptides* the antennæ are inserted near the base of the head, and have generally a terminal stylet; the tarsi are furnished with three small cushions; the femora are elongated; the wings have two submarginal and generally five posterior cells. The Leptides are remarkable for the habits of their larvæ, which excavate funnel-shaped cavities in the sand, and, secreting themselves at the bottom, lie in wait for their prey. When an insect falls into the pit, the larva of the *Leptis* suddenly rising seizes it, and clapping the body sucks out the juices, after which it flings away the carcass. The sub-family *Dolichopoda* is distinguished by the second joint of the palpi being membranous, depressed, and covering the base of the proboscis. The stylet of the antennæ is sometimes dorsal and sometimes apical; the eyes are generally separated in both sexes; the abdomen is somewhat cylindrical, or approaches a conical form; wings decumbent, without any discoidal cell, and generally possessing four posterior cells. The sub-family *Syrphidæ* is a very extensive group, and although given by Macquart as a division of his family *Brachystoma*, certainly constitutes a section of higher value than a sub-family. [SYRPHIDÆ.]

LEPTOCEPHALUS, a remarkable fish of the Eel tribe, discovered on the British coast in Pennant's time, and since observed in the Mediterranean. The *Leptocephalus Morrisii* is a small, slender, and compressed animal, as thin as a piece of tape, and at first sight resembling a marine worm. The head is extremely small and short, the eyes large, the jaws furnished with numerous minute teeth, the pectoral fins and gill-openings very small, and the anal and dorsal fins connected with the tail. The outline of the body resembles that of the Lancelet (*Branchiostoma*); but the organization of the *Leptocephalus* is that of a perfect fish. Mr. Yarrell describes the vertebrae as having no spinous processes. It lives among sea-weed.

LEPTOCOCHUS, Dr. Rüppell's name for a genus of pectinibranchiated gastropodous Molluscs, remarkable for their subglobular, delicate, fragile, translucent shell. Example, *Leptocochnus striatus*, Rüppell. Locality, the Red Sea, where it is found in coral (*Meandrina Phrygia*), having no communication with the water except by a moderate opening.

LEPTOPHINA, Mr. Bell's name for a sub-family of snakes belonging to the family *Colubridæ*. All the species are arboreal in their habits, entwining themselves among the branches of trees, and gliding from one to another with great rapidity. They are extremely elongated and slender in form, and glitter with metallic hues. Their food consists of young birds, large insects, &c. Two genera are described, *Dryinus* and *Leptophis*.

LEPTOSOMUS, a genus of birds established by Vieillot, and belonging to the family *Cuculidæ*. Example, *Leptosomus afer*; *Cuculus afer*, Gmel.; Edolian Cuckoo of Shaw, found between Calcutta and Benares, and in the Vindhyan mountains.

LEPUS. [LEPORIDÆ.]

LEPUS (the Hare), one of the old constellations, said by Hyginus to be in the act of running from Orion's dog, which is the greater dog according to some, and the lesser according to others. It is situated directly under Orion.

LERIDA. [CATALUNA.]

LERISTA, a genus of reptiles belonging to the family *Scincidæ*, established by Mr. Bell, and thus characterized by him:—Head scutated; no eyelids; the ears hidden under the skin; the body slender; the scales smooth and equal; feet four; the anterior little, very short, and didactylous; the posterior longer, and tridactylous; vent simple, semicircular. Example, *Lerista lineata*, which is bronze green, paler beneath, with two dorsal and two lateral black lines. Locality, Australia.

LERNEA, the *Lernæans*, which M. de Blainville collected into a family with that name, are parasitic animals adhering to fishes, and have presented some difficulty to zoologists as to their natural position. Cuvier placed them at the end of his *Intestinaux Cavitaires*, Cavitary Intestinal Worms, *Entozoa Nematoidea* of Rudolphi, but as a very different family, and requiring to be divided into many genera when their economy is better known. The better opinion seems to be that they are crustaceans, and Milne-Edwards so considered them.

LESAGE, ALAIN RÉNÉ, the author of 'Gil Blas,' was born 8th May, 1668, at the village of Sarzeau, near Vannes in Brittany, and was educated at the Jesuit college of Vannes. He went to Paris in 1692, and qualified himself as an *avocat*; marrying in 1695 the daughter of a citizen whose face was her only fortune, but with whom he enjoyed for many years complete domestic happiness. He supported himself entirely by literature till the Abbé de Lyonne gave him a pension of 600 livres. He wrote upwards of a hundred dramas, the principal being 'Turcaret,' 'Don César Ursin,' and 'Crispin,' which attained great popularity. His comic novels won for him a still higher place in literature, and have never been excelled by anything of the same kind. 'Le Diable Boiteux,' or 'Devil on Two Sticks,' had a prodigious success, and Sir Walter Scott declared the principal character, Asmodeus, to be as much a creation of genius as Ariel or Caliban. In 1715 he published the first two volumes of the work on which his fame mainly rests. Completed by the publication of a fourth volume in 1735, 'Gil Blas de Santillane' occupies in French fiction the same place as 'Don Quixote' in that of Spain, and 'Tom Jones' and 'Roderick Random' in that of Britain. There exists

little doubt, however, that Lesage based his fiction on the work of some obscure Spanish writer; nor does this detract from his admirable merits. He took the dry bones and made them live; clothed them with flesh, as Shakspeare did the legends and stories on which he founded his dramas. Lesage died at Boulogne on the 17th of November, 1747.

LESLIE, SIR JOHN, was born April 16, 1766, at Largo, a village on the coast of Fifeshire. He studied at the University of St. Andrews, and afterwards travelled in America as a private tutor. He eventually became a contributor to the *Monthly Review*, in London, and furnished notes for a new edition of the Bible. After spending some years on the Continent, he was elected to the Professorship of Mathematics in the University of Edinburgh. At this period his only production relative to pure mathematics was an essay on 'The Resolution of Intermediate Equations.' In 1809 Mr. Leslie was called to the chair of Natural Philosophy. He was knighted June 27, 1832, and died November 3 in the same year, at his residence in Fifeshire.

Besides some other works, Sir John Leslie has left—'Elements of Geometry, Geometrical Analysis, and Plane Trigonometry,' 'Geometry of Curve Lines,' 'Philosophy of Arithmetic,' 'Account of Experiments and Instruments depending on the relations of Air to Heat and Moisture,' 'Elements of Natural Philosophy' (containing Mechanics and Hydrostatics). Sir John Leslie also furnished several important papers to the 'Edinburgh Philosophical Transactions,' the 'Encyclopædia Britannica,' the *Edinburgh Review*, and to *Nicholson's Philosophical Journal*. Some papers on physical subjects were also read before the Royal Society of London, though not printed in their 'Transactions.'

LESPARRE. [GIRONDE.]

L'ESPINASSE, MADEMOISELLE, the name of a lady much celebrated in the Parisian literary circles soon after the middle of last century, was born in 1732. She is supposed to have been the illegitimate daughter of people of rank. She was employed to read to and converse with Madame du Defand in her blindness; but being ambitious, well-informed, and eloquent, she attracted the interest of the circle surrounding Madame du Defand to herself. She died in 1776. Three volumes of her love-letters, conspicuous for very ardent eloquence, were published in 1809.

LESSINES. [HAINAUT.]

LESSING, GOTTHOLD EPHRAIM, was born at Kametz in Upper Lusatia, of which place his father was pastor, January 22, 1729. His attachment to reading displayed itself from his earliest childhood. From a school at Meissen he was sent to the University at Leipzig. His first literary productions were one or two minor dramatic pieces, which were printed in a journal entitled *Ermunterungen zum Vernügen*.

In conjunction with his friend Mylius he began a quarterly publication at Berlin, *Beiträge zur Historie des Theaters*, which, however, was not carried on beyond its fourth number. After some minor speculations, he formed a close intimacy with Moses Mendelssohn and Nicolai, which had a highly beneficial influence upon each of them. One of the first results of their joint studies was the dissertation,

'Pope als Metaphysiker' (1754), the object of which was to show that the English poet had no fixed philosophical system. His next work was his 'Miss Sara Sampson,' the first specimen of domestic tragedy in German literature.

In 1757 he and his friends undertook the *Bibliothek der Schönen Wissenschaften*, which may fairly be said to have been the best literary journal Germany could then boast of. To this period, from 1753 to 1760, during which he resided at Berlin, belong his 'Fables' and his 'Litteraturbriefe,' or 'Letters on Literature' (1759), a life of Sophocles, after the manner of Bayle, and a translation of Diderot's dramatic pieces. From 1760 to 1765 Breslau was his residence, he having accepted the appointment of government secretary to General Von Tauenzien. Here he seems to have injured his health by the excitement of the faro-table; but eventually giving up both play and his appointment, he returned to Berlin, and published his celebrated 'Laocoon.' The following year was marked by another triumph, namely, his 'Minna von Barnhelm,' and the succeeding one by his 'Dramaturgie' and the 'Antiquarische Briefe.' His 'Emilie Galotti' was published in 1772. His last drama, 'Nathan,' was also almost the last of all his literary productions. He had entered only into his fifty-third year when he died, February 15, 1781.

His brother, Karl Gotthelf Lessing (born 10th July, 1740), who published his biography and some posthumous pieces, in 1793, wrote several comedies, which exhibited considerable dramatic talent.

L'ESTRANGE, SIR ROGER, was born in Norfolk in 1616. Like his father, he was a royalist, and accompanied Charles I. to Scotland in 1639. He was arrested by the emissaries of the Parliament in 1644, and sentenced to be shot as a spy, but escaped in 1648, and attempted to raise an insurrection in Kent. This having failed, he fled the country, but returned in 1653, hoping to take advantage of the general act of amnesty. Cromwell having taken his part, his hopes were realized. After the Restoration he was appointed censor of the press, and in 1665 he brought out a paper called the *Public Intelligencer*. He was devoted to the court, and on the approach of the Revolution of 1688 lost all his appointments. He died in 1704. His works consist of a vast number of political pamphlets, besides indifferent translations of Josephus, Cicero's 'Offices,' Seneca's 'Morals,' Erasmus' 'Colloquies,' Æsop's 'Fables,' Quevedo's 'Visions,' &c.

LE SUEUR, JEAN-FRANÇOIS, Knight of the Légion d'Honneur, and director of the music of the Emperor Napoleon, was born in 1776. After having been maître de chapelle of several cathedrals in France, for which he composed a great number of masses, motets, &c., his reputation called him to Paris, where he produced his five grand operas:—'La Caverne,' 'Paul et Virginie,' 'Télémaque,' 'Les Bardes,' and 'La Mort d'Adam.' His work on music, adapted to sacred solemnities, is highly esteemed.

LETHARGY, a state of unnaturally deep and prolonged sleep, a condition intermediate between the sleep of health and complete coma. If not the result of unusual fatigue, it is often an alarming symptom, indicating congestion of the brain, and a disposition to apoplexy, or even an impending attack of that disease.

LETHE. In Greek mythology, the river of oblivion. Its waters possessed the quality of causing those who drank them to forget the whole of their former existence.

LETTER OF CREDIT, [CREDIT, LETTER OF.]

LETTER or POWER OF ATTORNEY is an instrument by which one person authorizes another to do some act for him: it may be used in any lawful transaction, as to execute a deed, to collect rents or debts, to sell estates, and other like matters. The authority must be strictly followed. The power which authorizes an attorney or agent to do some particular act impliedly includes an authority to do whatever is incident to that act. But the authority never goes beyond that which is given in terms, or is absolutely necessary for carrying the authority into effect.

The authority must be executed during the life of the person who gives it.

Powers of attorney are generally executed by deed, and where they contain an authority to bind the principal by deed, it is essential that they should be so executed. When the agent signs any instrument which is to bind his principal, he must sign it in the name of the principal, and not in his own name.

A power of attorney, unless it be given as a security, is revocable, either directly, or indirectly by the principal granting a new power to another person. But if the power has been given as a security, it is not revocable by the principal.

A letter of attorney is also in general revoked by the bankruptcy of the principal, unless it is coupled with an interest.

The person having the power cannot delegate his authority.

LETTERKENNY. [DONEGAL.]

LETTERS OF MARQUE were abolished among European nations at the treaty of Paris in 1856. Before that time, all vessels making war upon, or seizing the property of another nation, without carrying a commission called letter of marque, granted by the lords of the Admiralty, were treated as pirates. This referred principally to privateers.

LETTERS PATENT, the king's letters, sealed with the great seal. These grants, says Blackstone, ('Comment.' b. ii. ch. 21), whether of lands, honours, liberties, franchises, or anything else that can be granted, are contained in charters or letters patent, that is, open letters, *littere patentes*. They are so called because they are not sealed up, but open to view, with the great seal pendent at the bottom, and are usually directed or addressed by the king to all his subjects at large. They are now frequently granted under the royal authority as the reward of ingenuity, and are in some cases the only means by which a man can secure any compensation for a discovery, or for the labour and expense which he may have employed in perfecting an invention. The consideration of the legal rights of patentees, and of the modes in which they may be acquired and secured, properly belong to the head of **PATENT**. Many letters patent have been granted by the king to the founders of schools and other charitable endowments, empowering the donor to make rules and ordinances for the government of his charity, and constituting into a body corporate those persons and their successors whom the founder should choose to nominate.

LETTERS, THREATENING. [THREATS.]

LETTER-WOOD is the heart of a tree found in the forests of British Guiana, and belongs to the bread-fruit family *ARTOCARPACEÆ*. It is called letter-wood on account of the beautiful black marks on its rich dark-brown wood, which bear some slight resemblance to the old black-letter printing. The outer layers of the tree are white, and only the central portion or heart is of this dark colour; it is also extremely hard and heavy. It is scarce and valuable, and used for fine veneers and inlaying.

LETTRES DE CACHET. [CACHET, LETTRES DE.]

LETTUCE (the *Lactuca sativa*, or Garden Lettuce) is one of the principal kinds of vegetables used for salads, and it also forms an ingredient in some kinds of soup. It has been introduced and cultivated in this country for nearly three centuries, but, like many other domesticated plants, its origin is unknown. The excellence of lettuces consists in their being crisp and tender; their growth should therefore sustain no check or interruption.

The ground intended for the seed should be fresh dug, rich, and mellow. The principal summer crop should be sown in March and April, and the seed lightly covered. If the plants are intended to attain their full perfection where sown, they must be thinned out to distances of nine inches square in the case of the small cabbage varieties, and the larger sorts should be allowed at least a foot each way. Water should be given, but not at any one time to excess, not merely at the root of each plant, but over the whole of the ground.

The Cos Lettuces require to have their leaves tied together moderately close with a strip of matting, for the purpose of assisting their blanching and rendering them more crisp and delicate. This should be done about a week previous to their attaining full perfection.

LEUCADIA. [SANTA MAURA.]

LEUCHTENBERG is a lordship in the kingdom of Bavaria, which has an area of 84 square miles. In 1817, Maximilian Joseph, king of Bavaria, gave it, with the principality of EICHSTADT, to his son-in-law, Eugene Beauharnois, who assumed the title of Duke of Leuchtenberg. The title of royal highness was conferred on the duke and his successors, who were also declared capable of succeeding to the throne, in case the royal line of Bavaria should become extinct.

LEUCIN, a name given by Braconnot to a substance obtained by the action of dilute sulphuric acid upon fibrin. Leucin is white, pulverulent, very soluble in water, and crystallizable. The crystals, when heated to above 212°, fuse and suffer partial decomposition, and exhale an odour of roast meat.

LEUCISCUS, a genus of fishes of the family *Cyprinidæ*, distinguished by having short and soft anal and dorsal fins, and a mouth unfurnished with barbules. There are many species, well-known inhabitants of the rivers of Europe. Those best known in Britain are the Roach (*Leuciscus rutilus*), the Dace (*Leuciscus vulgaris*), the Chub (*Leuciscus cephalus*), the Rudd (*Leuciscus erythrophthalmus*), the Bleak (*Leuciscus alburnus*), and the Minnow (*Leuciscus phoxinus*). More rare are the Graining (*Leuciscus Lancastriensis*), and Azurine (*Leuciscus*

caruleus), formerly supposed to be peculiar to the north of England, but stated by Agassiz to inhabit certain Swiss lakes. The Dobule (*Leuciscus dobula*), a native of the rivers of Western Germany, has been taken by Mr. Yarrell in the Thames, and the Ide (*Leuciscus idus*) is doubtfully recorded as a native of Scotland. Most of these fishes are sought after by anglers, either for the sport they afford or to be used as bait for pike. None of them are very excellent as food. The roach and chub have been known to attain a weight of five pounds.

LEUCITE, *Amphigene*, occurs imbedded in lava in trapezoidal crystals, and massive; the colour is yellowish white, and the lustre vitreous. The crystals have various degrees of translucency. The massive varieties are granular. It consists chiefly of silica, alumina, and potash.

LEUCOMA, a white opacity of the cornea. [EYE.] It is the result of acute inflammation producing a deposition of lymph on the surface and in the layers of the cornea, either with or without ulceration of its substance.

LEUCTRA. [EPAMINONDAS.]

LEUWENHOEK, or LEEUWENHOEK, ANTHONY VAN, was born at Delft, in Holland, in 1632. He does not seem to have had the advantage of a learned education. Dr. De Graaf introduced him to the notice of the Royal Society of London, and the greater number of his discoveries and researches were published in the 'Philosophical Transactions' of that body. In 1680 he was chosen a fellow of the Royal Society, and he was made a corresponding member of the Academy of Sciences at Paris in 1697. He appears to have passed the whole of his life at his native place, devoting his time to microscopic researches, chiefly relating to anatomy; and the

success which attended his observations is said to have principally arisen from his having paid the most minute attention to the grinding and polishing of single lenses, which he always used in preference to the compound microscope.

Leuwenhoek died at Delft in 1723. Besides his contributions to the 'Philosophical Transactions,' he published about twenty-six papers in the 'Memoirs of the Academy of Sciences.'

LEUZE. [HAINAULT.]

LEVA'NT, or LEVANTE, an Italian word which means the East, and which is also commonly used, especially among seafaring and commercial people of the countries bordering on the Mediterranean, to designate the eastern or Asiatic shores of that sea, namely, those of Syria and Asia Minor, the harbours of which are styled 'Scale di Levante,' in French 'Echelles du Levant' ('stairs of the East'). Smyrna, Alexandretta, Beyrout, Acre, the harbours of Cyprus, and other islands near the coast of Asia, are included within this denomination.

LEVANTER, the name given to an easterly wind blowing up the Mediterranean.

LEVEE, the state ceremonial of the sovereign receiving at court those subjects who are entitled to that honour. A levee differs from a drawing-room in that it is exclusively for gentlemen.

LEVELLING is the art of determining the heights or depressions of points on the ground with respect to a spherical or spheroidal surface coinciding nearly with that of the earth, or, when the extent of ground is inconsiderable, with respect to a horizontal plane passing through some given point on the ground.

The relative heights of a series of points on the ground are obtained by means of their vertical distances from others which, on the supposition of the

earth being a sphere, are equally distant from its centre; and these, which are called level-points, must be found by an instrument constructed for the purpose. [SPIRIT LEVEL; THEODOLITE.] In general, a choice is made of any convenient stations, A, B, &c., on the line of operation, and the distances between them are determined by actual admeasurement. The instrument is then set up at or near the middle of the interval between every two such points in succession. When the telescope thus placed, as at *a*, has been rendered horizontal by means of the adjusting screws, an assistant at each of the stations A and B, holding what is called a station staff in a vertical position, moves a vane or index along the staff, upwards or downwards, according to the directions of the observer at the telescope, till it appears to coincide with the intersection of two wires in the telescope.

The points thus determined on the staves are represented by *m* and *n*; and these are level-points, or points equally distant from the centre of the earth. Therefore the heights *Am* and *Bn* being read on the graduated staves, the difference between them will

give the relative heights of the ground at A and B. A similar process is repeated with respect to the points, B and C, the instrument being placed at *b*, midway between them; and the operation is to be continued to the end of the line on which the profile is required. It is customary to insert the heights, *Bn*, *Cq*, &c., in a column headed *Fore Sights*, in a sort of field-book, and the heights, *Am*, *Bp*, &c., in a collateral column headed *Back Sights*. The difference between the sums of the numbers in these two columns will be equal to the height of one extremity of the line above the other.

It is, however, very frequently the practice to execute a sort of double-levelling; which consists in placing the instrument successively at each of the stations, A and B, a staff being held up vertically at the other, when the axis of the telescope being at equal heights from the ground at both stations, half the difference between the heights read on the staves will express the height of A above B. This is strictly correct, however, only on the supposition that the visual rays at both stations are parallel to one another, and it must be evident that in very extensive sur-

veys some allowance must be made for the earth's curvature.

On ascending or descending a steep hill, no other method can be adopted than that of placing the instrument at one extremity of the station-line and the staff at the other; but as these lines are then necessarily very short, the deviation above mentioned need not be regarded.

The profile of the ground is usually expressed on paper, in portions of any convenient length, for the purpose of enabling the engineer to determine the depths of his excavations, or the heights of the masses of earth to be raised, when it is proposed to execute a railway or road. A right line being drawn to represent one parallel to the horizon, and passing through the highest or the lowest point of the natural ground, the heights or depressions of the remarkable points, as A, B, &c., with respect to such line, are obtained by additions or subtractions from the numbers in the field-book, and are, by a proper scale, set out from that line on others drawn perpendicularly to it at intervals equal to the horizontal distances between the same points. The series of points thus obtained, being joined by hand or otherwise, give the figure of the required vertical section of the ground.

LEVEN, LOCH. [KINROSS-SHIRE.]

LEVER (*levare*, 'to lift up'), the name of a common mechanical instrument, consisting of a simple bar of wood or metal, by fixing one point of which, called the fulcrum, a pressure at the end more distant from the fulcrum is made to counterbalance a larger pressure at the nearer end; or if both ends be equally distant from the fulcrum, equal pressures are made to balance each other.

The first explanation of the lever was given by Archimedes, and that in so simple a manner, that while his method has always been the best for a popular view of the subject, it has never been surpassed, or even equalled, in rigour or purity, considered as a foundation for the science of Statics.

It assumes two principles; firstly, that when a system is in equilibrium, the state of rest will not be disturbed if additional pressures, such as compensate each other, and would by themselves produce no motion, be introduced or removed; secondly, that when a weight is made to rest by being attached to an immovable point (say it is suspended by a string), the point or pivot of suspension undergoes a pressure equal to the weight of the system, whatever may be the form of that system, or the dispositions of its parts. Thus, a cylindrical or prismatic bar of uniform material will necessarily rest if a pivot be passed through a section in the middle of its length, since there is no reason why it should preponderate on either side; now, divide the bar into any two parts, and from their middle points suspend weights equal to the weights of the parts; also apply counterpoises of equal weights at the same points, by means of strings passing over pulleys; the equilibrium will then be undisturbed; take away from the system the parts of the bar and the counterpoises (which are equal and opposite to one another), and the equilibrium will subsist between the remaining weights, which are those first suspended. The points of suspension being in the middle of the lengths of the two parts, are at distances from the pivot (at the middle

of the whole length of the bar), which are inversely proportional to the suspended weights.

The most simple way in which the preceding result can be stated is as follows: when a weight, V, placed at K balances a weight, W, placed at L, about the pivot, A, the number of pounds in V multiplied by the number of feet in KA gives the same product as the number of pounds in W multiplied by the number of feet in AL. (Any other units of weight and length will do equally well, if only the same be used in both.) The product of a pressure and the perpendicular let fall upon its direction from a fixed pivot or fulcrum is sometimes called the moment, sometimes the leverage, of the weight.

In English treatises on mechanics it is customary to call one of the pressures which balance on a lever, the power, and the other the weight. Levers are thus distinguished as of the first, second, or third kind, according as the fulcrum, the weight, or the power, is in the middle.

LEVERIDGE, RICHARD, a celebrated singer towards the end of the seventeenth and beginning of the eighteenth centuries, for whom Purcell wrote most of his bass songs. He is best known by his music to Gay's 'Black-Eyed Susan.' During his life, Leveridge published several of his songs, in two 8vo volumes. He died in 1758.

LEVITES, among the ancient Jews, descendants of the tribe of Levi, who were usually employed in the inferior offices of the temple, in which they were distinguished from the superior priests who were of the same race, and from those who were of the family of Aaron. The Levites applied themselves to the study of the law, sang, and played upon instruments in the temple. They were also the inferior judges of the country. They were divided into three classes; the first for preparing the offerings for sacrifice; the second for the performance of the vocal and instrumental music; and the third for taking charge of the gates of the temple, and preventing the entry of intruders in the sacred ground. For their sustenance they had the tithes of forty-eight cities allotted them, with fields, gardens, and pastures for their habitations.

The tribe of Levi is the only one which is supposed to have maintained its lineage pure to this day, and certain signs of distinction are still bestowed upon its members, more especially in the case of the presumed descendants of Aaron.

The name Levite is also given to certain sacerdotal assistants in the Roman Catholic Church.

LEVITICUS, a canonical book of the Old Testament, being the third of the Pentateuch, supposed to be written by Moses; and so called from its containing the regulations relative to the priests, Levites, and sacrifices.

LEVY, the act of a compulsory raising of a body of troops for the defence of a country or for the purposes of war. The mode of making a levy varies with the purpose for which it is raised. If only for recruiting the army, the district selected may draw them by lot from the males of the required age. In other cases, it is restricted to a class, as for instance, all men between the ages of twenty and twenty-five.

In very urgent cases, a general levy is made of all persons capable of bearing arms. In Britain the army is well sustained, and its vacancies filled by volunteers; in France by conscription; but in America, during the late civil war, large levies were raised at various times. In some instances, those on whom the lot falls can only escape serving by providing an able-bodied and healthy substitute.

LEVYNE occurs crystallized; primary form, an acute rhomboid. It is whitish, translucent, and has a vitreous lustre. Its elements are silica, alumina, lime, soda, potash, magnesia, and water, of which the first occupies about one-half the whole weight.

LEWES. [SUSSEX.]

LEWIS, an island of Scotland. [Ross and Cromarty.]

LEWIS, MATTHEW GREGORY, a writer of novels, poems, and dramatic pieces, was born at London on the 9th of July, 1775. Lewis studied at Christ Church, Oxford, and afterwards lived for some time in Germany. There he became acquainted with Goethe and his followers, and imbibed the mysterious and tragic spirit of which his writings are full. Previously to his residence in Germany, when only sixteen years old, he wrote a successful comedy, called 'The East Indian.' The novel by which he is chiefly known, 'The Monk,' was published in 1794, when he was in his twentieth year. In 1812 he introduced to the stage the drama of 'Timour the Tartar,' which is said to have had much influence in creating a taste for gorgeous pageants. His best dramatic work is 'The Castle Spectre.' Lewis died at sea, on the 14th May, 1818.

LEWIS, SIR GEORGE CORNEWALL, BART., English statesman and author, was born in London in 1806. He was the eldest son of Sir Thomas Frankland Lewis, who from 1821 to 1839 filled several important public offices—among them the vice-presidency of the Board of Trade and the chairmanship of the Poor Law Board. Sir George was educated at Eton and Christ Church, Oxford, where he graduated B.A., in 1828, as first-class in classics and second in mathematics. Three years afterwards he was called to the bar at the Middle Temple, and after acting on various commissions of inquiry, he was appointed a poor-law commissioner, an office which he retained till 1847. Meanwhile he found time for the composition of several works, political and literary. In 1836 he published a disquisition on 'Local Disturbances in Ireland, and the Irish Church Question;' and in 1839 two philological works, entitled 'Glossary of Herefordshire Provincial Words,' and an 'Essay on the Origin and Formation of the Romance Languages.' In 1841 he published a political 'Essay on the Government of Dependencies.' Entering Parliament as member for Herefordshire, in 1847, he became successively secretary to the Board of Control, under-secretary for the Home Department, and financial secretary to the Treasury, going out of office with the Whigs on the accession of Lord Derby to power in 1852. Before this time he had published two elaborate and argumentative works—one in 1849, 'An Essay on the Influence of Authority in Matters of Opinion,' and the other 'A Treatise on the Methods of Observation and Reasoning in Politics.' From July, 1852, to February, 1855, Sir G. C. Lewis was not only out of office, but

VOL. VIII.

out of Parliament, having been defeated as a candidate for the representation of Herefordshire in the former month, and for that of Peterborough in the November following. In the meantime he became editor of the *Edinburgh Review*, and wrote his great work, 'An Inquiry into the Credibility of the early Roman History,' in which, impugning the reconstructive system of Niebuhr, he sought to disprove the credibility of the Roman history for the first 473 years of the city. Re-entering Parliament in March, 1855, as member for the Radnor burghs, which he represented until his death, he resigned the editorship of the *Edinburgh Review*, and held the post of chancellor of the exchequer till the dissolution of Lord Palmerston's government in 1858. On the return of the Whigs to power in 1859, Sir George was appointed Home Secretary, an office which, to the surprise of the nation, he exchanged in 1861, on the death of Lord Herbert, for that of Secretary of State for War. In the same year he published a work of much research, entitled the 'Astronomy of the Ancients.' His latest work was a 'Dialogue on the Best Form of Government.' Sir G. C. Lewis married, in 1844, Lady Maria Theresa Villiers, sister to the earl of Clarendon; succeeded to the baronetcy on the death of his father in 1855; and died, from congestion of the lungs, on April 13, 1863. A statue has been erected to his memory at Hereford, and his bust placed in Westminster Abbey.

LEWISHAM. [KENT.]

LEX MERCATORIA, or LAW-MERCHANT, in a general sense, denotes the usages and customs of merchants, which, having been adopted as part of the law of most countries, and particularly of maritime states, for the protection and encouragement of trade, have been termed a branch of the Law of Nations. (Blackstone's 'Commentaries.')

The term Lex Mercatoria, when used with reference to English law, like the Lex et Consuetudo Parliamenti, merely describes a general head or division of the system. What customs or rules are comprehended under that division must always be matter of law for the consideration of the judges; and it was said by Chief Justice Hobart, that, if they doubt about it, they may 'send for the merchants to know their custom, as they may send for the civilians to know their law.' The principle seems to be as alluded to by Lord Hale in a case in Hardres' 'Reports,' p. 486, that the courts are bound to take notice of the general law of merchants; but that, as they cannot know all the customs which form part of that law, they may inform themselves by directing an issue or making inquiry in some less formal manner. The latter mode has frequently been adopted in modern times, and evidence of mercantile customs has often been given before juries. When the custom is ascertained, the court may declare it to be legal or not, according to their judgment; for the expression, that the court is bound to take notice of the general law of merchants, does not mean, or should not mean, that the custom, simply as such, must be recognized as law by the judges. The recognition of the custom by the judges makes it law.

LEXICON. [DICTIONARY.]

LEXINGTON. [KENTUCKY; MASSACHUSETTS.]

LEYCESTERIA, a genus of plants of the natural

family of *Rubiaceæ*. The genus consists of only a single species, *L. formosa*, a native of the Himalaya mountains, at elevations of from 6000 to 7000 and 8000 feet, in Nepal and Sirmore, where it grows among oaks and pines, and is therefore well suited to the climate of England, where indeed it may be seen growing in great luxuriance, as well as in the south and west of Scotland.

LEYDEN, a city of the Netherlands, the capital of a canton, 22 miles S.W. of Amsterdam, and 17 N. from Rotterdam (with both of which it is connected by canals and railways), is situated in 52° 9' 30" N. lat., 4° 29' 13" E. long., on a branch of the Rhine, and had, in 1862, 37,339 inhabitants. The town is traversed by many broad canals, which are bordered with trees, and which, intersecting each other, divide it into fifty small islands, connected together by 145 bridges. It is surrounded with a rampart, on which are fine shady walks; and outside there is a deep and broad moat, crossed by eight bridges leading to as many gates. The city is well built, and the principal streets are broad and well paved. The street in which the town-hall is situated extends nearly across the city from east to west; it is almost 2 miles in length, and is reckoned one of the handsomest in Europe. The houses are mostly of brick, with the gable-ends to the streets. Among the public buildings the most worthy of notice are—the town-hall; St. Peter's Church, the finest of the seventeen in the city; the great hospital; the arsenal, custom-house, and chamber of commerce. An ancient castle or fort, ascribed by tradition to the Romans, stands in the middle of the city, and commands an extensive prospect of the town and the surrounding country. The manufactures of linen and woollens have declined considerably, but are still the most important in Holland. In the middle of the seventeenth century, Leyden had 100,000 inhabitants. Its principal trade is in grain, butter, and cheese. The most remarkable event in the history of Leyden is its successful resistance to the Spaniards in 1573, when it sustained a severe siege; it was ravaged by the plague in 1655, and was greatly injured by an explosion of gunpowder in 1807. The university, which was founded in 1575, and was once the most celebrated in Europe, has an extensive library of books, and rare Oriental manuscripts, a valuable botanical garden, an observatory, a museum particularly rich in Japanese, Egyptian, and Etruscan antiquities, and a cabinet of natural history. The attendance of students is about 420. There are, besides, several private museums, and many learned societies.

LEYDEN JAR, a vessel employed in electrical experiments, so called from M. Vanleigh, of Leyden, the inventor. The preparation of this jar consists in a coating of tin-foil, inside and out, to within one-third of the top, in order that it may be readily charged and discharged by means of a metallic rod, which is in communication with the interior coating. [CHEMISTRY.]

LEYDEN, LUCAS VAN, a very celebrated old Dutch painter and engraver, was born at Leyden in 1494. He distinguished himself even as a boy by his engravings, and was a famous painter as early as his twelfth year. He painted in distemper a picture of St. Hubert, in 1506, for a citizen of Leyden

of the name of Lokhorst, who was so gratified at the excellence of the work, that he paid him twelve gold pieces for it, one for each year of his age. Some of Lucas' early engravings are highly prized by print-collectors, and accounted among the greatest rarities of their class. He died in 1533, aged only 39.

L'HOPITAL. [HÔPITAL.]

LIAS, in Geology, the name of a series of argillaceous and calcareous strata, forming the basis of the oolitic system. The name is supposed to be derived from the appearance of the bed in layers in the quarries where it is worked, in the middle of England. It overlies the new red sandstone series, and is everywhere remarkable for its fossils. Among these are included the *Ichthyosaurus*, *Plesiosaurus*, *Pterodactyle*, and other giants of the primeval world. [GEOLOGY.]

LIBANUS. [SYRIA.]

LIBATION (Lat. *libo*, 'I pour'), an essential part of sacrifice among the Greeks and Romans. It consisted in the offering up of any liquid to the gods, usually of wine, water or milk. Libations were also made at funerals, and at banquets.

LIBAU. [COURLAND.]

LIBEL (from the Latin *libellus*, 'a little book') is a malicious defamation, expressed either in writing, or by signs, pictures, &c., tending either to blacken the memory of one who is dead, or the representation of one who is alive, and thereby exposing him to public hatred, contempt, or ridicule. (Hawkins, 'P. C.')

This species of Defamation is usually termed *written scandal*, and it is generally treated as a more serious mode of defamation than Slander. [SLANDER.]

Whatever written words tend to render a man ridiculous or to lower him in the estimation of the world amount to a libel, although the very same expressions, if spoken, would not have been slander or defamation in the legal sense of those words. To complete the offence, publication is necessary, that is, the communication of the libel to some person, either the person himself who is libelled, or any other. The mere writing of defamatory matter without publication is not an offence punishable by law; but if a libel in a man's handwriting is found, the proof is thrown upon him to show that he did not also publish it.

Libellers may be punished by indictment or criminal information and by action.

Indictment or criminal information is for the public offence (as it is termed), for every libel has a tendency to a breach of the peace by provoking the person libelled; the civil action, which is on the case, is to recover damages by the party for the injury caused to him by the libel.

The truth of a libel was formerly no justification in a criminal prosecution; yet it was so far considered an extenuation of the offence, that the Court of King's Bench would not grant a criminal information unless the prosecutor by affidavit distinctly and clearly denied the truth of the matters imputed to him, except in those cases where the prosecutor resided abroad, or where the imputations were so general and indefinite that they could not be expressly contradicted, or where the libel was a charge against the prosecutor for language held by him in Parliament.

A fair report of judicial proceedings does not

amount to a libel, but a publication of *ex parte* proceedings before a magistrate may be punished as such.

A petition containing scandalous matter, presented to Parliament or to a committee of either House, and legal proceedings of any kind, however scandalous the words used may be, do not amount to a libel. But if the petition were delivered to any one not being a member of Parliament, or the legal proceedings were commenced in a court not having jurisdiction of the cause, they would not be privileged. Confidential communication reasonably called for by the occasion, as charges made by a master in giving the character of his servant to a party inquiring after it, or a warning by a person to another with whom he is connected in business, as to the credit or character of a third party about to deal with him, are considered as privileged communications, and are not deemed to be libels unless malice be proved, or the circumstances be such that malice may be inferred by the jury.

It was settled by an Act of Parliament that the jury must find not only the fact of publishing, but whether the matter in question be a libel or not (32 Geo. III. c. 60, extended to Ireland by 33 Geo. III. c. 43). In a civil action the question whether the publication is or is not a libel is decided by the judge or court.

The punishment in a criminal prosecution may be fine and imprisonment; and upon a second conviction for publishing a blasphemous and seditious libel, the court might sentence the offender to banishment for any term it might think fit. (1 Geo. IV. c. 8.) But this was repealed by 11 Geo. IV. & 1 Will. IV. c. 73.

The printer of a libel is liable to prosecution as well as the writer, and so is the person who sells it, even though he is ignorant of its contents.

By the 28th section of 38 Geo. III. c. 78, a bill of discovery may be supported against the editor of a newspaper, or other person concerned in the publication, or interested in the property thereof, to compel a disclosure of the name of the author of the libel, or of the name of any person connected with the publication against whom the party libelled may think proper to bring an action; and such a bill may also be obtained against any person suspected of being the author, which would compel him to discover on oath whether he did or did not write the libel in question. (Holt, 'On Libel.')

The Act of 6 & 7 Vict. c. 96, entitled 'An Act to amend the law respecting Defamatory Words and Libel,' has made some alterations in the law of defamation and libel. It enacts—Sec. 1, That in any action for defamation it shall be lawful for the defendant, subject to a certain notice in writing therein described, to give in evidence, in mitigation of damages, that he made or offered an apology to the plaintiff for such defamation at such time as in the said section is more particularly described.

Sec. 6 makes an important change: it enacts, That, on the trial of any indictment or information for a defamatory libel, the defendant, having pleaded such plea as in this section is afterwards mentioned, the truth of the matters charged may be inquired into, but shall not amount to a defence, unless it was for the public benefit that the said matters charged should be published. The defendant must in his plea to such indictment or information allege the

truth of the matters charged in the manner that is required in pleading a justification to an action for defamation.

Sec. 7 enacts, That when on the trial of any indictment or information for the publication of a libel, under the plea of Not Guilty, evidence shall have been given which shall establish a presumptive case of publication against the defendant by the act of any other person by his authority, it shall be competent to the defendant to prove that such publication was made without his authority, consent, or knowledge, and that the said publication did not arise from want of due care or caution on his part.

This Act does not extend to Scotland (s. 10). As it was doubted whether or not it appertained to Ireland, this Act was extended to Ireland by 8 & 9 Vict. c. 75.

Defamation and libel were punished among the Romans. The various rules of Roman law on this subject are stated in Rein, 'Das Criminalrecht der Römer.'

In Scotland a libellous or defamatory attack upon a person's character or reputation may be the foundation of a criminal prosecution at the instance of the public prosecutor, or for a civil action for damages and reparation, which may now proceed before a jury. The amount of injury or loss suffered, actual or probable, and the insult or offence to the individual, are both to be considered in an action for damages on the ground of libel. Malice need not in general be averred, but it must be stated and proved in the case of actions of libel against persons who, from their position or duties, are privileged in interfering with the conduct and character of others. Members of Parliament, judges and counsel in courts of justice, and members of corporations, in inquiries relating to which the body has cognizance, have this privilege; but this is not extended to members of the General Assembly of the Church of Scotland, except when sitting as a court of justice. The press is free: but it is not entitled to animadvert upon the conduct and character of individuals, except in their public capacities. *Veritas conviciū*, or the truth of the statement complained of, is a good defence to a civil action of damages for libel, as tending to disprove the *implied* malice which is always presumed in such cases. The term *libel* is also used in Scotch law to denote the form of complaint, or ground of charge, on which either a civil or a criminal action proceeds. (Bell's 'Dict.,' art. *Libel*).

LIBELLULA, the genus of insects which includes the well-known Dragon-flies. It belongs to the order *Neuroptera* and to the section *Subulicornes* in the arrangement of Latreille. The dragon-flies have horny strong mandibles and maxillæ, covered by the labrum and labium; their tarsi are three-pointed; their wings are equal; the posterior extremity of the abdomen is furnished with hooks or peculiar appendages. The size, beauty, and habits of these insects have rendered them favourite objects of study with the entomologist. In the larva state they live entirely in the water, engaged in unceasing war with other insects, which by singular devices they entrap and devour. Their pupa state is also passed in water, and contrary to the usual habits of insects, is a period of activity and locomotion. They are then furnished with an extraordinary mask formed out of

that part of the head which replaces the lower lip, and by which they cover the jaws and the whole under part of the head. They use it to alarm and seize their prey, projecting it at will. When perfect insects, they become inhabitants of air, and are endowed with extraordinary power of flight and precision of movement, performing astonishing evolutions. Their habits continue as ferocious as they were before. Several valuable monographs have been published on these interesting insects, but one of the most important is that of the distinguished Belgian zoologist, M. de Selis Longchamps, entitled 'Monographie des Libellulidées d'Europe.' In this work sixty-one species are described, arranged under the genera *Libellula*, *Cordulia*, *Lindenia*, *Gomphus*, *Cordulegaster*, *Æstha*, *Anax*, *Calepteryx*, *Lestes*, *Sympecma*, and *Agriion*.

In the arrangement of Westwood ('Introduction to the modern Classification of Insects') the genera of *Libellulidæ* inhabiting Britain are grouped under two sub-families, *Libellulidæ* and *Agriionidæ*. The following are the British genera: Sub-family 1, *Libellulidæ*.—*Anax*, 1 species. *Æstha*, 7 species. *Cordulegaster*, 1 species. *Gomphus*, 2 species. *Cordulia*, 3 species. *Libellula*, 15 species. Sub-family 2, *Agriionidæ*.—*Agriion*, 13 species. *Lestes*, 3 species. *Calepteryx*, 4 species.

LIBER, the inner bark of a plant, is a layer consisting of woody tissue, cellular substance, and vessels of the latex, forming a compact zone immediately applied to the wood. The woody tissue of which it is composed quickly becomes thick-sided, by the addition of internal ligneous strata, the consequence of which is, that such tissue in this part is more tough than elsewhere. Hence it is usually from the liber that are extracted the fibres employed in making cordage or linen-thread: this at least is its source in hemp, flax, the lime-tree, the lace-bark, and the many other exogens which furnish thread; but in endogens, which have no liber, as the cocoa-nut, it is the ordinary woody bundles of the leaves, stem, and husks of the fruit from which the fibre used for ropes is procured. It is said that certain exogens, such as *Menispermaceæ*, have no liber. In many plants a new layer of liber is formed annually, contemporaneously with a new layer of wood; but this is by no means universal; on the contrary, the oak and the elm increase their liber slowly and irregularly.

LIBER REGIS, another term for the *Valor Ecclesiasticus* of the 26th Henry VIII., is the book which contains an account of the valuation of the whole ecclesiastical property of England and Wales, on the eve of the Reformation. By an act of the 23rd of Henry VIII., the payment of annates, or the first-fruits of bishoprics and archbishoprics, with all sums paid for palls, bulls, and the like, at the consecration of every new prelate, was restrained. This was followed by an Act in the 26th Henry VIII., for the payment, not only of 'first-fruits of all dignities, benefices, and promotions spiritual,' but also of an 'annual pension of the tenth part of all the possessions of the church, spiritual and temporal, to the king and his heirs,' as supreme heads of the Church of England. The *Valor Ecclesiasticus* is the return which the commissioners under this Act made into the exchequer. This record, in full, except certain portions which have been lost, was published under

the orders of the commissioners upon the records of the realm, in six vols. folio, London, 1810-34. An abridgment of it is preserved in the Office of First-Fruits, entitled '*Liber Valorum*,' and was the foundation of the '*Liber Regis*, vel *Thesaurus Rerum Ecclesiasticarum*,' by John Bacon, Esq., receiver of the first-fruits, with an appendix, &c., 4to, London, 1786. This latter work also contains an account of such benefices as have been since discharged from any payment to the above revenues, on account of the smallness of their income. Queen Anne, in the second year of her reign, gave up first-fruits and tenths to trustees who were empowered to administer them for the benefit of the poorer clergy. This gift of the queen was confirmed by Act of Parliament, 2 & 3 Anne, c. ii.

LIBERIA is the name of an independent negro republic of Western Africa, established in 1822, which extends along the coast of Guinea, between lat. 4° 50' and 7° N.; long. 6° 50' and 12° 39' W. Its sea-board extends 600 miles, including the colony of Cape Palmas, with an average breadth of 100 miles. The area is about 23,000 square miles. The inhabitants belong to all nationalities of Africa, and were computed, in 1863, to number altogether 422,000, of whom 16,000 were born in the United States, and 6000 were rescued from slave-ships. The establishment of Liberia is due to the Americans. In 1816 the American Colonization Society was established at Washington for the purpose of founding a colony of emancipated negroes. The first attempt to carry out their idea proved unsuccessful, in consequence of the unhealthiness of the site chosen; but in 1822 they purchased Cape Mesurado, upon which Monrovia, the capital (so called from President Monroe), now stands. Purchases of other territory were subsequently made, and in 1839 the several settlements were united as a commonwealth. In 1847 this gave place, with the desire of the settlers, and with the consent of the Colonization Society, to the present republic of Liberia. The state was first acknowledged by England (whose government made it a present of a corvette of war with four guns, its only navy), afterwards by France (who supplied its 1500 militia with muskets), Belgium, Prussia, Brazil, Denmark, and Portugal, and, in 1861, by the United States. The republic has the facility of almost indefinite extension into the interior. It is stated that the natives everywhere manifest the greatest desire that treaties should be formed with them, so that the limits of the republic may be extended over all the neighbouring districts. The Liberian territory has been acquired by more than twenty treaties, and in all cases the natives have freely parted with their titles for a satisfactory price. The chief solicitude has been to purchase the line of sea-coast, so as to connect the different settlements under one government, and to exclude the slave trade, which formerly was most extensively carried on at Cape Mesurado, Tradetown, Little Bassa, Digby, New Sesters, Gallinas, and other places at present within the republic. Many of the natives have become useful citizens, serve on juries, act as magistrates, and one of them has been elected and serves creditably as a member of the Liberian House of Representatives.

The constitution of the republic of Liberia is on the model of that of the United States of America. The

executive is vested in a president and a non-active vice-president, and the legislative power is exercised by a Parliament of two houses, called the Senate and the House of Representatives. The president and vice-president are elected for two years; the House of Representatives also for two years, and the Senate for four years. There are thirteen members of the Lower House, and eight of the Upper House; each county sending two members to the Senate. Every man above twenty-one years of age, who possesses a real estate of the value of 30 dollars, has a vote; and it is provided that, on the increase of the population, each 10,000 persons will be entitled to an additional representative. Both the president and the vice-president must be at least thirty-five years of age, and possess real property to the value of 600 dollars, or 120*l*. In case of the absence or death of the president, his post is filled by the vice-president.

For political and judicial purposes, the republic is divided into four counties, called Montserrado, Grand Bassa, Sinoe, and Maryland, which are further subdivided into townships. The townships are commonly about eight miles in extent. Each town is a corporation, its affairs being managed by officers chosen by the inhabitants. Courts of monthly and quarter sessions are held in each county, whose civil business is administered by four superintendents appointed by the president with the consent of the Senate. The county system of government is capable of indefinite extension over new districts of territory that may be acquired, giving to the inhabitants all the advantages which local self-government affords. The government of Liberia is entirely in the hands of the African race.

English is the official language, and is spoken by the negroes from the United States. All are Protestants, Popery being proscribed. There is a good supply of churches, and a system of common-school instruction is provided by the government. Several institutions of a more advanced character are supported by the benevolence of the American people. A college, erected at a cost of 20,000 dollars, is open at Monrovia, having a faculty of three (coloured) professors, and about twenty-five students. Newspapers are published, and there is a regular postal system. The number of immigrants from the United States, from 1820 to 1856, was 9562, of whom 3676 were free-born. In general, those who migrate from America are despatched into the interior, where the soil is better, and the climate more healthy than on the coast. Carysburg, White Plains, and other stations, have been thus established. In the year 1862 the public revenue amounted to 30,190*l*., and the expenditure to 29,973*l*. The Liberians have built and manned thirty coast traders, and they have a number of large vessels engaged in commerce with Great Britain and the United States. Systematic drainage and clearing the woods have greatly improved the climate.

Palm-oil, camphor, ivory, gold-dust, coffee, indigo, ginger, arrow-root, and hides, are exported. Cocoa and sugar thrive, and recently cotton has been grown. Mandingo horses and native cattle are used for draught, but much of the camwood exported is brought 200 miles from the interior on men's backs. It is estimated that 2,000,000 of the inhabitants of the interior now obtain supplies of European goods from the

republic and Cape Palmas; and that the Liberians exercise Christian influence over 480,000 natives. The church of Liberia was reorganized in 1862.

The seaport is *Monrovia*. The other chief settlements are Bexley, Edina, and Cresson—the latter situated on a fine bay, and affording abundant supplies of wood and water. *Edina* is named after Edinburgh, from which city considerable pecuniary aid was sent to Liberia in 1834. The increasing usefulness and universally admitted success of Liberia are adduced by the friends of the negroes as proofs that they are thoroughly capable of self-government under fair and proper conditions.

(*Statesman's Year Book*, 1866; *Malte Brun*; Parliamentary Papers; Private Information.)

LIBERTINUS. In the Roman polity persons were divided, with respect to status or condition, into freemen (*liberi*) or slaves (*servi*). Freemen, again, were divided into persons who were born in a state of freedom (*ingenui*), and libertini, or those who had been manumitted. A manumitted slave was called *libertus*, that is, *liberatus*, 'freed,' with reference to the act of manumission, and to his master, who, by manumitting him, became his patron (*patronus*): he was called 'libertinus' with reference to the class to which, by the act of manumission, he belonged.

A manumitted slave might either become a full Roman citizen or a *Latinus*, or he might obtain no higher privileges than the class called *Dediticii*. The grounds and conditions of this triple distinction are fully explained by Gaius (i. 12, &c.)

LIBERTY. This word is the Latin *libertas*. The corresponding Teutonic word is *freiheit*, or as it appears in English, *freedom*. [Law.]

LIBERTY. The general nature of a liberty, as a portion of the royal prerogative in the hands of a subject, has been already shown under **FRANCHISE**.

The fines paid to the Crown for grants or confirmations of liberties are shown by Madox to have formed no inconsiderable part of the royal revenue.

The form in which the Crown granted views of frankpledge [LEET] and other franchises may be seen in the charters granted by King Henry VI. to Eton College, and King's College, Cambridge.

A person exercising a franchise to which he has not a legal title may be called upon to show cause by what authority he does so, by a writ of *Quo warranto*, or an information in the nature of a *Quo warranto*; and parties disturbed in the lawful exercise of a franchise may recover damages against the disturber in an action on the case.

LIBOURNE. [GIRONDE.]

LIBRA (the Balance). In the older Greek writers the Scorpion occupies two constellations of the *ZODIAC*, or rather the body of the animal occupies one, and the claws, *chelæ* (*χελαι*), another. We say this, because, though the *chelæ* were certainly a part of the Scorpion, yet they are often mentioned (as by Aratus for instance) by themselves, as if they formed a distinct constellation. The word *chela* had several significations; so that it may have been by simple mistranslation that the Romans (according to Hyginus, Virgil, &c.) gave the name of *Libra* to the part of the heavens in question, and drew back the claws of the Scorpion to make room for the scales.

Libra is surrounded by Scorpio, Ophiuchus, Virgo, Centaurus, and Lupus.

LIBRA, among the Romans, a pound weight, equivalent to the *as*, or twelve ounces. It was also the name of a coin consisting of twelve ounces of silver, or ninety-six drachmæ, worth about 3*l*. of our money.

LIBRARIES. The word library signifies a collection of books arranged for use, and also the building or apartment in which such a collection may be kept. The term is sometimes applied to a series of works uniformly printed on a single or on several subjects, such as the 'Library of Old Authors,' &c.

In ancient times it is easy to suppose that when books began to be multiplied libraries would be founded, not only for purposes of study, but for the preservation of archives and other documents, which a barbarous system of warfare rendered it desirable should be kept in places of great security. The origin of libraries may thus be carried back to the Hebrews (Ezra vi. 1), whose care in preserving their sacred books became an example to other nations, particularly to the Egyptians. According to Diodorus Siculus (i. 58) Osymandyas, king of Egypt, had a library built in his palace with this inscription above the door, *Ψυχῆς Ιατρείον* ('the dispensary of the mind'), and sculptures on the walls representing 'a judge with the image of truth hanging from his neck, and many books lying before him.' What adds to the interest of this statement of Diodorus is the circumstance, that by recent discoveries in Egypt this building has been identified as the *Memnonium*—a palace temple near Thebes, believed to have been built in the fourteenth century B.C. In describing the apartments of this building, Osburn, in his 'Monumental History of Egypt,' says: 'The last of these halls was a library, and the approach to it was through a gilded doorway, according to the inscription that still remains upon it.'

The most famous library of Egypt, perhaps of the ancient world, was founded at Alexandria by Ptolemy Soter, about 290 years B.C. No expense was spared on the collection, which at length amounted to 500,000 volumes. After subsisting for 244 years, it was burned during the expedition of Cæsar to Egypt. Another collection existed at Alexandria till 642, when it shared the same fate.

Among the Greeks libraries were numerous. Pisistratus founded a library at Athens, which, after undergoing many vicissitudes, subsisted till the time of Hadrian. Polycrates founded one at Samos, and large collections of books were made by Euclid, Euripides, and especially by Aristotle, whose library was purchased by Ptolemy and incorporated with the Alexandrine. There was also a famous library at Pergamus, founded by Eumenes, which, according to Plutarch, contained 200,000 volumes.

The first library at Rome was that of Paulus Æmilius (167 B.C.), the contents of which had been carried off from Macedonia. The most celebrated were the Octavian and Palatine public libraries, established by Augustus, the latter of which continued until the time of Pope Gregory I.; the Ulpian library, erected in Trajan's Forum by the Emperor Ulpian Trajanus; besides others in the principal cities and colonies of the empire. In the fourth century there were twenty-eight public libraries in Rome; and the number of calcined volumes found at Herculaneum and Pompeii prove that collections of books were common in those cities.

Constantine erected at Byzantium, or Constantinople, a magnificent library, which under his successors reached the number of 200,000 volumes. It remained till the seventh century, when it was burnt by command of the Emperor Leo III.

During the Middle Ages the Moslems had an important library of Arabic books in Alexandria, and one at Bagdad, which included Greek MSS. In Spain they had seventy public libraries in the twelfth century, and that at Cordova contained 250,000 volumes. In the West, libraries were attached to nearly every large church, while the Benedictine, Franciscan, and other monks collected in their religious houses many volumes, which at the Reformation were dispersed, and found their way into the libraries of universities, cities, and princes.

The invention of printing brought about a new era in the history of libraries, the number of books being greatly increased. Shortly after this may be dated the foundation of several of the more famous libraries of Europe, a list of which is subjoined.

The taste for forming libraries has perhaps been more developed in England than in any other country. This may be accounted for partly by the wealth of the collectors and the laws of the country, which favour the preservation of property of every kind in the same family for a long time. Thus England possesses many ancient private libraries, while on the Continent, with the exception of Austria, there remain few or none.

Among the more important private libraries in England may be mentioned those of Earl Spencer, at Althorp; the earl of Ellesmere, at Bridgewater house; the duke of Devonshire, at Chatsworth; the duke of Marlborough, at Blenheim; Sir Thomas Phillipps, at Middlehill, Worcestershire; the earl of Leicester, at Holkham; and Lord Ashburnham, whose library contains a fine collection of MSS. Among the Scottish private libraries may be mentioned those of the duke of Hamilton, at Hamilton; the duke of Buccleuch, at Dalkeith and Bowhill; the marquis of Lothian, at Newbottle; the earl of Dalhousie, at Brechin castle; Mr. Hope Scott, at Abbotsford; J. T. Gibson Craig, Esq., J. W. Mackenzie, Esq., D. Laing, Esq., at Edinburgh; and W. Euing, Esq., and J. Smith, Esq., of Jordanhill, at Glasgow.

At the present time libraries are found so indispensable for the sustenance of learning, that they are still more attracting the attention of the public. In 1855 Mr. Ewart's Act (18 & 19 Vict., c. 70) was passed, for the establishment of libraries and museums in country towns in England. It extends to all boroughs whose population exceeds 10,000; but before it can be carried into effect, a public meeting of ratepayers must be called, and the consent of two-thirds of those present obtained. In England free rate-supported libraries have been already established in Manchester, Liverpool, Salford, Boston, Warrington, Oxford, Cambridge, Westminster, Norwich, Winchester, Sheffield, Lichfield, Kidderminster, Leamington, and Birkenhead. Preliminary steps have been taken in other towns for this purpose.

In Scotland and Ireland the Acts 17 & 18 Vict., c. 64, and 18 & 19 Vict., c. 40, make similar provision for the establishment of libraries. In Scotland, however, a poll for the purpose may be demanded by any five qualified voters, which poll must be taken

within two days after the meeting at which it shall have been demanded. As yet only the preliminary steps have been taken for the purpose of establishing free libraries in Edinburgh, Glasgow, and Aberdeen. In Ireland the towns of Ennis and Dundalk alone have taken advantage of the Libraries' Act.

The following tables show the extent of the principal libraries of Great Britain, Europe, and America:

Library Economy.—This subject embraces all matters relating to the construction and management of libraries designed for the use of the public.

That a collection of books may deserve the name of a public library, it must be classed according to some system, and arranged for easy reference. A library, whether public or private, whether it contains a million or only a few hundred volumes, will only be useful so long as it is arranged and managed according to a plan in harmony with its purposes.

The more important matters pertaining to this subject may be shortly treated of as follows:—

1. *The Construction of Library Buildings.*—The essential conditions are preservation from fire and water, and a situation remote from a noisy or dangerous neighbourhood, but at the same time at the command of the public resorting to them; in their

Fig. 1.

Fig. 2.

internal distribution to have respect to economy of space and the possibility of enlargement; and by a proper system of heating and ventilation, to seek the

preservation of the books from injurious influences, such as insects, dust, &c.

The design most suitable and convenient for a library hall is that of a long and large gallery lighted from above, or from the two sides, and intersected by cases placed back to back, thus forming recesses communicating with a passage in the middle (fig. 1); or this gallery may be divided lengthwise by a range of bookcases similarly back to back, which thus form parallel (fig. 2) rows of cases. Besides the hall intended to contain the library itself, there must be in addition a reading room and several smaller apartments for the general business of the library.

2. *Furniture*.—The most suitable height for library bookcases is from 8 to 10 feet, and if the apartment be lofty a light gallery of perforated iron, accessible by a small spiral staircase, may be continued above the first row of cases, with a light balcony in which a second set of cases may be placed. The shelves in these cases should commence about three or four inches from the floor, and may be placed at the following distances from each other:—Folios, 16 to 18 inches; 4tos, 10 to 11 do.; 8vos, 8 do.; 12mos, 7 do. Their depth should be about 15 inches, to allow the circulation of air. It is also necessary to know the sizes suitable for the reception of various classes of works. For instance, the fathers of the Church, Bibles, the councils, and schoolmen require more space for folios than for 4tos or 8vos; the belles-lettres, again, require in general only shelves of the height for 8vos or 12mos; natural history, geography, travels, antiquities, architecture, furnish 4tos and 8vos in equal proportions, but require a special place for the atlases ordinarily accompanying such works.

Ladders should be substantial, but light enough to facilitate their continual shifting. Oak is preferable to all other wood for library furniture, as it is less liable to the attacks of worms, and is easily kept clean.

3. *The Classification of the Books*.—Many systems of classification have been proposed. The most convenient, however, is that of Mr. Hartwell Horne, modified from the one originally proposed in France by Father Garnier, in 1678. It is as follows:—I. Theology; II. Jurisprudence; III. Philosophy; IV. Arts and Trades; V. History; VI. Literature.

Under these comprehensive divisions books of every kind may be classified, and the numbering and marking of the volumes may be made in accordance with them. The six divisions may be denoted by the letters A, B, C, D, E, F; each of these may have twenty-six subdivisions, Ea, Eb, Ec, to Ez; these again may have twenty-six subdivisions, Ea +, Ea Δ, Ea ±, and so on to almost any extent: for example, the first volume of 'The History of Europe,' by Sir A. Alison, 20 vols., 8vo, Edinburgh, 1847, would bear the mark—

Eh.	{E. Class <i>History</i> .
+	{h. Division <i>Modern History</i> .
9514	+ Subdivision <i>History of Europe</i> .
	9514. No., of Books in 8°.
1	1. No. of Volume.
8°	8° Size.

In the British Museum, and some other large

libraries, a system of arrangement called the *expansive* has been adopted. The library is divided into presses, each of which has a number; the shelves of each press are distinguished by a letter of the alphabet, and the place of each book on a shelf is indicated by a number; thus 573 c 13, means the thirteenth book on the third or c shelf of press 573. The numbers of the presses, however, are not in immediate sequence,—thus, supposing the first press to be numbered 1, and the works under the class Theology to occupy two presses, twenty numbers would nevertheless be allotted to this class. The first three numbers of the presses would then be 1, 2, 20. When a third press should come to be required for theological works, instead of placing them in another part of the library the books in the press marked 20, together with its number, would be moved on to the next press, and the press occupied by No. 20 would be called No. 3. By this process all the works belonging to one class are kept together for a longer period than under other systems. This arrangement, however, involves two indispensable conditions, viz., sufficient space, and that all the presses should be exactly of the same size.

4. *Catalogues*.—The catalogue of a large library should contain the transcription of the titles of the books in the following order:—The name of the author; the exact title, with the name of the editor or annotator; the number of volumes; the size; the name of the town where published, with the name of the publisher and printer; and the date. In addition, each entry in the catalogue should have the distinctive letters of the class and division to which the work described belongs, and also the running number in the library arrangement.

Besides the general catalogue, which should be constructed according to the authors' names in alphabetical order, there should also be shelf catalogues, or lists of the contents of a library shelf by shelf. These last are useful, when the books themselves are carefully classified, as furnishing to some extent a *catalogue raisonné* of a library.

5. *Stamping, Binding, &c.*—In every large library the stamping or marking of the books is an important matter. This should be applied at the beginning and end, and also on a certain leaf on the middle of each volume (in the Royal Library of Paris it is the 101st). Each plate and map should also be stamped, but in such a way as not to be injured. The binding of the books [BOOKBINDING] should in every case be made suitable to the importance and value of the books.

6. *Classification of Manuscripts, Prints, and Coins*.—Many libraries contain, besides books, collections of manuscripts, prints, and coins. The first may be arranged according to the six divisions indicated above, s. 3. For the classification of prints the twelve following heads may be adopted:—

1. Sculpture, architecture.
2. Religion, morals, sacred emblems, and devices.
3. Fiction, Greek and Roman antiquities, &c.
4. Genealogy, chronology, heraldry, coins, numismatics.
5. Public festivals, cavalcades, tournaments, and carousals.
6. Geometry, machines, mathematics, military art, music, arts and trades.

7. Romances, facetiæ, buffooneries, caricatures.
8. Natural history, anatomy.
9. Geographical and historical maps.
10. Ancient and modern monuments, and topography.
11. Portraits.
12. Fashions, costumes, manners.

Each class is divided into schools, and each school into its masters.

For coins, the following is the classification adopted in the principal cabinets of Europe:—

1. Ancient coins of—1, kings; 2, cities; 3, of Roman families (consular); 4, emperors; 5, deities, heroes, and illustrious men.

2. Modern coins of—1, Europe; 2, other parts of the world; 3, tokens.

Each series may be divided into gold, silver, bronze.

For full details of the matters which fall to be treated of with regard to libraries in general, see Edwards' 'Memoirs of Libraries,' 2 vols., 8vo, published in 1859, which is the best work on this interesting subject.

LIBRARIES, MILITARY. For several years past a sum of four or five thousand pounds has annually figured in the army estimates of Great Britain for supplying and maintaining our troops with libraries. The charge for 1865 was 4560*l*. Military libraries are of two kinds, *garrison* and *regimental*. The former comprises a large collection of books, with newspapers, games, and a commodious reading and lecture-room; and the latter merely collections of books which accompany regiments in their various movements. The introduction of these libraries has been found to improve the *morale*, without injuring the efficiency of our soldiers.

LIBRATION, (Latin *libratio*, from *libra*, 'a balance') a balancing motion, in which there is a position on one side and the other of which a body vibrates, being in fact the same in meaning as oscillation. This term is, however, particularly applied to a small irregularity, compounded of the moon's rotation round her axis, and her orbital motion, by means of which her visible hemisphere is not always quite the same.

The mean revolution of the moon round her axis is the same period of time as her mean revolution in her orbit. If both motions were equable, the moon would always present the same face to a spectator placed at the centre of the earth, on condition that the plane of her equator passed through the centre of the earth. None of these conditions being exactly fulfilled, and the variation being small and periodic, the consequence is that a small portion of the moon's surface in the eastern and western edges, and also in the northern and southern, is alternately visible and invisible.

LIBYA. [AFRICA.]

LIBYAN DESERT. [DESERT.]

LICENSES are grants of permission by the state, allowing subjects to vend or deal in exciseable articles, and to exercise various callings from which the country derives a revenue. Most of these will be found fully described in the various articles to which they refer, as **ALCOHOLE**, **AUCTIONEER**, **GAME**, **MARRIAGE**, &c.

The subjoined table enumerates all the different kinds of licenses now granted in the United Kingdom, the number issued, and the amount of duty

accruing to the exchequer therefrom in the year ending March 31, 1865:—

Description of License.	Number issued in				Amount of Duty.

LICENTIATE IN MEDICINE is a physician who has a license to practise granted by the College of Physicians. There are two classes: licentiates who are authorized to practise in London and within seven miles thereof; and extra-licentiates, who are only privileged to practise in the country at a greater distance from the metropolis. The former class are authorized exclusively by the College of Physicians, but medical graduates of Cambridge or Oxford may practise in the provinces independently of the college license.

LICHANOTUS, Illiger's name for a genus of Cheilopeds or Quadrumanes (*Indris* of Lacépède, Geoffroy, and others) belonging to the *Lemurida*.

The *Indris* are inhabitants of Madagascar, and two species only seem generally recognized, namely,

Indri brevicaudatus of Geoffroy, *Lemur Indri* of Gmelin; and *Indri longicaudatus* of Geoffroy, *Lemur laniger* of Gmelin, *Indri laniger* of Fischer.

A specimen of the Short-tailed Indri, in the Paris Museum, presented the following particulars. Anterior part of face nearly naked; forehead, temples, and throat, white; ears, occiput, shoulders, arms, and hands, black; lower part of back brown, dividing on the haunch into two lines, which run down the buttocks and spread on the thighs, leaving the croup, the tail, and the posterior part of the thighs, white; feet and anterior part of thighs deepened into black; heels white, with an anklet of grayish white; chest brown; abdomen white, as is also the inside of the arms; the thumbs, especially those of the hind paws, very large and powerful; fore toe small, and tied to the next, almost to the last, joint; nails small, flat, sub-keeled and pointed; first toenail long, flat, and sharp; fur beautifully soft and woolly. Length of head and body, $24\frac{1}{2}$ inches; of tail, 3 inches; of hind foot, $7\frac{1}{2}$ inches.

A Lemurine animal termed *Envahis laniger*, would seem to be identical with the *Indri longicaudatus* of Geoffroy, and *Lemur laniger* of Gmelin. Its characteristics are—Hind limbs extremely long, and hind thumbs of extraordinary size; fur peculiarly soft, delicate, and curly, finer than wool; ears small, round, and buried in the fur; colour, rusty brown gray, the hairs of a leaden tint at the base; face, brighter red brown; on the knees and forearms a decided tinge of red brown; throat, chest, abdomen, gray; a spot on the haunches over the hip joint, and the back of the thighs white; tail round, bright rufous or chestnut red. Length of head and body of the most perfect specimen, 15 inches; of tail, 14 inches; of hind foot, $4\frac{1}{2}$ inches. Fore hands long and slender; thumb, thin and feeble. [LEMURIDÆ.]

LICHENIN, a peculiar vegetable product, sometimes called Lichen Starch. It is obtained from the *Cetraria islandica*, or Liverwort. When pure, it is white, and it retains water; but on drying it becomes yellowish. In thin plates it is transparent. It is tough, tasteless, nearly inodorous, swells up when put into cold water, but dissolves sparingly in it. It is composed of nearly equal equivalents of oxygen, hydrogen, and carbon.

LICHENS (Gr. *leichen*), a large and important natural order of imperfectly organized plants, containing numerous species employed in the arts as pigments, and as articles of food. It is principally in the former respect that they are of economical interest, in consequence of the great consumption of orchal, or archil [ARCHIL], Cudbear (*Lecidea tartarea*), and others by the dyer.

Lichens are perennial plants, requiring free access to light and air, of the most simple organization, forming irregular patches upon the surface of stones, trees, the earth, and other bodies. They are distributed over all parts of the world, forming in the polar and similar regions a food for animals and man. *Cladonia rangiferina* supports the reindeer, *Cetraria islandica* furnishes the nutritious Iceland moss of the druggists' shops; and various species of *Gyrophora*, under the name of Tripe de Roché, form a part of the supply of food scantily furnished by nature for the Canadian hunter. In warmer countries they acquire a firmer consistence, and appear

to form secretions of a peculiar kind in much greater abundance than in the northern parts of the world. (See Plates.)

Lichens are directly opposed to Fungi, as they are perennial, and consist of a lobe and leaf-like thallus. They are usually found in those northern regions where more delicately-formed plants cannot exist. The annexed is the representation of a lichen, called the *Jungermannia*, the fructification of which is here represented.

Fructification of the *Jungermannia*.

A is a very young spore-case, still covered by the calyptra; B, the same quite developed in the hyaline, ripe and bursting, and presenting to view the inclosed spores.

The *Promelia perforata* is a beautiful variety of lichen with projecting shields.

Promelia perforata.

Dr. Lindley, in his 'Natural System of Plants,' places the *Lichenales* among the Asexual or Flowerless plants (Class I., *Thallogens*), and describes them as 'Cellular flowerless plants, nourished through their whole surface by the medium in which they vegetate; living in air; propagated by spores usually inclosed in asci; and always having green gonidia in their thallus.' He estimates the number of genera at 58, and the species at 2400. He also classifies the family under the natural orders, *Graphidaceæ*, or Letter lichens; the *Collema*ceæ, or Jelly lichens; and the *Parmellaceæ*, or Leaf lichens.

LICHFIELD. [STAFFORDSHIRE.]

LICHTENBERG, a principality of 220 square miles, with 38,000 inhabitants, formerly called the lordship of Baumholder, and now included in the Prussian Rhein-Provinz. It was ceded in 1816 by Prussia to the duke of Saxe-Coburg, who gave it the rank of a principality, and who held it till 1834, when it was again given up to Prussia for an equivalent of 80,000 dollars a year.

LICHTENSTEIN, a sovereign principality, the smallest of all the states composing the German con-

federation, is situated between the Rhine, Switzerland, and the Tyrol, on the northern slope of the Rhetian Alps, the highest summits of which rise to an elevation of 5610 feet. Its area is 63 square miles, or about one-third of the county of Rutland; its population is little over 7000, of the Roman Catholic religion. The country is very mountainous; but it produces corn, flax, wine, fruit, and timber, sufficient for the consumption of the inhabitants, who have also a good breed of horned cattle.

The capital, *Vaduz* or *Lichtenstein*, is a market town on the right bank of the Rhine, with a population of 1700. A new constitution was given to the principality on October 15, 1862, in consequence of some popular agitation. By the terms of the new fundamental law, the whole legislative power is vested in one House of Representatives, comprising fifteen members, three to be chosen by the reigning prince, and the other twelve by the people in public election. A vote is given to all inhabitants who can read and write; but to become a deputy a small property qualification is required. The chamber assembles every year in regular session, without being summoned by the prince. The latter is bound by the constitution to reside in the country for part of the year, and to appoint a governor in his absence.

There exists no public budget, all taxation being of a local kind. The total revenue for 1862 amounted to 55,000 florins, or 5500*l.*, and the expenditure to very nearly the same. Lichtenstein has no public debt. To the army of the confederation the principality has to contribute 91 foot soldiers; but no troops are kept under arms.

The princely family of Lichtenstein is said to derive its origin—together with the reigning houses of Great Britain, Hanover, and Brunswick—from the Longobard marquis d'Este, who married Cunizza, a Suabian heiress, at the commencement of the eleventh century. Partly on account of this antiquity of the family, and partly because of its immense wealth, the congress of Vienna, which sequestrated or 'mediatized' territories of much larger extent, left the principality of Lichtenstein a sovereign state, governed by its hereditary rulers. This diplomatic verdict, however, has not been ratified by the royal families of Europe, from whose circle the princes of Lichtenstein have hitherto been excluded. There are no blood alliances between any German or other reigning houses and the sovereign family of Lichtenstein. The members of the latter, all of them strict Roman Catholics, have allied themselves almost exclusively with the upper nobility of Austria, in which empire, and chiefly in the province of Moravia, the immense private estates of the family are situated. They embrace an area of over 2200 English square miles, with 350,000 inhabitants—or thirty-four times the extent, and forty-eight times the population of the principality of Lichtenstein—and yield an annual revenue of two millions and a half of Austrian florins, or 250,000*l.* From the principality itself the prince derives no income, but has been frequently under the necessity of advancing money to his subjects; the last time in 1847, when he made the state a loan of 36,000 florins. Formerly, the reigning prince resided entirely at Vienna, or at his castle of Eisgrub in Moravia; but the present

ruler has consented to reside part of the year at Vaduz, the capital of Lichtenstein.

LICINUS (Latreille), a genus of coleopterous insects included in the great group *Carabus* of the older authors. The genus *Licinus* is placed by Dejean in his section *Patellimanes*, and together with the genera *Dicalus*, *Rembus*, and *Badister*, constitutes a little section or sub-family, distinguished from other *Patellimanes* by the want of the tooth-like process in the emargination of the mentum. Three species of *Licinus* are British, and about twelve are known, most of which inhabit Europe.

LICTOR, a public officer who attended on the principal Roman magistrates. The kings, and afterwards the consuls, were attended by twelve lictors, the dictator by twenty-four, and the master of the horse by six. The duty of the lictor was to see that proper respect was paid to the magistrates, and to inflict punishment on those who were condemned. The lictors carried on their shoulders rods bound in the form of a bundle, with an axe in the middle.

LICUALA, a genus of Palms of the tribe *Coryphineæ* of Von Martius. A species, *L. peltata*, is described by Dr. Roxburgh as a native of the mountainous and woody parts near Chittagong. He mentions the narrow leaves of this tree as being formed into pipes for smoking tobacco, while the broader ones are employed for wrapping up fruit, and for other domestic uses.

LIÈGE, a province of Belgium, is bounded N. by Limburg, E. by Prussia, S. by Luxembourg, and W. by Namur and South Brabant. Its area is 1120 square miles, and the population in 1861 was 537,218, most of whom are Wallons. The southern portion of the province is hilly and undulating. The Ardennes mountains cover a great part of the south. The soil differs much in quality. On the west side of the Meuse, and on the east side towards Limburg, the plains, valleys, and low hills are fertile, well cultivated, and afford rich pasturage; on the east side of the Meuse, where it is joined by the Ourthe, especially towards Luxembourg, the ground is rocky and stony. In this part of the province there are extensive forests. The principal river is the Meuse, which comes from Namur, and forms at first the boundary between the two provinces. After receiving the Ourthe, it flows between high, steep, and often perpendicular rocks to the city of Liège, where it becomes broader; below this it flows N. by E. into the province of Limburg. The climate is healthy. The country produces hops, corn, and a little wine; the pastures maintain great numbers of horned cattle and sheep. The mineral wealth of the country is considerable; there are valuable mines of lead, zinc, and iron; but more important than all these together are the numerous coal mines of the provinces. Of the mineral waters those of Spa are the most celebrated. The manufactures, which are very important, consist of all kinds of steam machinery for railroads and factories, mill-castings, fine woollens, merinoes, linen, cotton stuffs, cutlery and surgical instruments, fire-arms, glass, hardware, &c. The province is crossed by the Liège-Namur Railroad, and by the line from Ostend to Cologne.

The capital is LIÈGE. *Glons*, a small place of 2000 inhabitants, 7 miles N. of Liège, is the centre of a great straw-hat manufacture. *Herstal*, or *Heristal*, on the left bank of the Meuse, has important

iron and coal mines, iron and steel works, iron-foundries, and 6000 inhabitants. Pepin-le-Gros took the name of de Heristal from having resided here. *Herve*, a few miles E. of Liège, has 3600 inhabitants, who manufacture woollen cloth, stockings, and shoes, and trade in cattle, cheese, and butter. *Huy*. [HUY.] *Limburg*, a small fortified town, which has nearly 2000 inhabitants, stands 16 miles N.E. from Liège, on the railway to Aix-la-Chapelle, and has manufactures of fine linen and woollen cloth. *Seraing* is 3 miles S.W. of Liège, on the right bank of the Meuse, and on the railway to Cologne. It is celebrated for its extensive iron and coal works, and for the manufactures of steam machinery, locomotives, and spindles, instituted by John Cockerill, an Englishman, in 1816, employing upwards of 5000 persons. This place has an ancient episcopal palace, and a suspension bridge, near which is the steam-packet station. Population (in 1864), 20,084. *Spa*, a well-built little town, famous for its mineral springs and baths, is situated in a pretty valley among the Ardennes mountains, in the south-east of the province, 17 miles S.E. of Liège. The heights around it are covered with plantations, and laid out in delightful walks, which present at several points prospects of great beauty. The principal spring, called Pouhon (over which Peter the Great of Russia built the pump-room in 1717), is situated in the town; six others are in the environs. The ordinary population is about 5000, who live chiefly by the profits derived from visitors to the waters. In 1860 it had 10,895 visitors, of whom 5334 were Belgians. The bath-buildings, the several pump-rooms, and the Redoute, a handsome building which includes a café, theatre, gambling-rooms, &c., are the most interesting structures in Spa. The Spa springs are chalybeate; they are chiefly recommended in cases of relaxation of the bowels and obstruction of the liver. About 150,000 bottles are annually exported from the Pouhon spring, which is the strongest. Spa is famous also for the manufacture of elegant wooden toys, workboxes, writing-desks, &c. The mountains near the town contain many beautiful and extensive grottoes. *Theux*, S.E. of Liège, on the railway to Aachen, has black marble quarries, woollen-yarn factories, iron-works, and 3000 inhabitants. *Verviers*, a flourishing manufacturing town of 29,000 inhabitants, is situated on the Vesdre, about 20 miles by railway E. from Liège. It is irregularly built; but some of the suburbs are pretty. The town-house, theatre, the new church, and the college, are the most remarkable public structures of the town. Verviers is famous for the manufacture of fine and ordinary woollen cloths, cassimirs, and yarn, giving employment to 40,000 hands in the town and neighbourhood; the Belgian army is clothed principally from the looms here, the total produce of which is estimated at 350,000 pieces, value 80,000,000 francs annually. For these, steam and water mills are employed. Flannels, serges, tickings, coverlets, mousselines de laine, merino, &c., are also manufactured. The dyes of Verviers are said not to be surpassed in Europe. There are also establishments for the manufacture of steam machinery, ironmongery, soap, beer, &c.

LIÈGE (*Lüttich*, *Luik*), the capital of the Belgian province of Liège, is situated in a valley at the junc-

tion of the Ourthe with the Meuse, in 50° 39' N. lat., 5° 31' E. long.; population, 97,500. It is the seat of a bishop, and of the supreme court of justice for Liège, Limburg, Namur, and Luxembourg. The Meuse, on entering the city, divides into several branches which form islands, bordered by handsome quays and connected by seventeen bridges. Liège is divided into the old and the new town, and has besides ten suburbs. Most of the streets are very narrow, dark in consequence of the height of the houses, and not clean. There are, however, a few broad streets, some good squares, and promenades. The city was formerly fortified, but at present it is defended only by a citadel, erected on St. Walbuge's Mount on the north side of the town, and by a great outwork on the west side. The most remarkable buildings are—the cathedral, built in the eighth century; the palace of justice, formerly the palace of the episcopal prince; the theatre; the church of St. Jacques; and the university, which was founded in 1817. There are a gymnasium, a bank, and numerous learned and charitable institutions. Amongst the latter are schools for the blind and for deaf mutes. The extensive coal mines near the town, which employ upwards of 10,000 miners; its numerous iron-works, royal cannon-foundry, and establishments for the manufacture of fire-arms, hardware, broad-cloth, glass, paper, watches, jewellery, and leather; its engine-factories, zinc-rolling mills, and naileries; its linen and cotton factories, steel-works, breweries, distilleries, and sugar refineries; together with a flourishing commerce in colonial produce and manufactured goods—render it one of the most important towns in Belgium, and one of the most industrial in Europe. It supplies fire-arms to nearly all the governments in the world, the exports of these only having doubled since 1859. It has a chamber of commerce and manufactures, cabinets of chemistry and natural history, a botanic garden, and a school of mines. It was the capital of the French department *Ourthe* from 1793 to 1814. In 1702 it was besieged and taken by the duke of Marlborough.

LIEGNITZ, one of the three governments into which SILESIA is divided, comprises the most north-westerly part of that province, and that part of Upper Lausitz which now belongs to Prussia. Its area is 4000 square miles, and the population in 1862 was 956,813.

Görlitz, a well-built fortified town, is situated on the left bank of the Neisse, 60 miles by railway E. from Dresden, and has a population of 26,534 civil, and 1449 military (1861). It contains thriving and extensive manufactures of linen and woollen cloths, bell foundries, steel and iron factories, lithographic-printing, and bleaching establishments. The town has also a considerable transit trade. It contains several churches, a citadel, a town-hall, high school, libraries, an orphan asylum, hospitals, a house of correction, a Protestant college, and a philosophical society, with a library and several MSS. *Görlitz* is walled, entered by eleven gates, and has three suburbs.

Glogau, a strong fortress on the left bank of the Oder, is situated in 51° 38' N. lat., 16° 7' E. long., 50 miles by railway E. from the Hansdorf station on the Frankfort-Breslau line, and has 16,000 inhabitants, including the garrison. An island in the Oder is strongly fortified, and connected with the town by

a wooden bridge. There are in Glogau many Roman Catholic and some Protestant churches, a synagogue, a citadel, and a garrison, Roman Catholic and Protestant colleges, &c. The principal articles manufactured are beet-root sugar, tobacco, paper, woollen and cotton fabrics, and straw hats. There is also a considerable corn market.

Liegnitz, the capital of the government, stands at the junction of the Schwartzwasser and the Katzbach, in 51° 12' N. lat., 16° 12' E. long., 180 miles by railway S.E. from Berlin, and has 18,600 inhabitants. The inner and older part of the town is surrounded with a moat and rampart of earth, which is laid out in gardens and planted with trees; it is entered by four gates. The chief buildings of the town are—two Lutheran and three Roman Catholic churches, a ducal chapel, an ancient council-house, an academy, an orphan asylum, and a workhouse. The manufactures are cotton and woollen stuffs, silk, linen, leather, and tobacco; and its vicinity is famous for horticulture. Formerly it was fortified; and here, on the 16th August, 1760, the Prussians, under Frederick the Great, totally defeated the Austrians.

Goldberg, situated on an eminence on the banks of the Katzbach, has double walls and gates: it is 11 miles S.W. of Liegnitz, and has 7500 inhabitants, most of whom are engaged in manufactures of woollen cloth, hosiery, and gloves. About six miles to the east is the hamlet of Wahlstadt, where the Prussians defeated the French, August 26, 1813. *Grünberg*, a walled town, with gates, has 10,700 inhabitants, and flourishing manufactures of woollen cloths and straw hats. The vine is extensively cultivated. *Herschberg*, S.W. of Goldberg, is the centre of a great linen manufacture, and has 7080 inhabitants. *Jauer*, or *Jauerbach*, stands 10 miles S. of Liegnitz on the Neisse. It is a well-built town, surrounded by a double wall and a ditch, and has 8000 inhabitants, who manufacture broad-cloth, linen, hosiery, and leather, and trade in corn and flax. *Lauban*, on the Queis, a walled town, with four gates, has 6800 inhabitants, who manufacture calico, tobacco, and linen. *Sagan*, on the Bober, is a strongly fortified town, with three gates, a very fine ducal palace with a beautiful park, one Lutheran and five Roman Catholic churches, hospitals, and manufactures of woollen cloth, linen, stockings, lace, sealing-wax, looking-glasses, &c. The population is a little over 8000. The railway from Glogau to Berlin runs through the town. The Prussians were defeated here by the Russians in 1759.

LIEN (from the French *lien*, 'a tie,' or 'band.') The following definition is perhaps as correct as any that has proceeded from the judges:—A lien is a right in one man to retain that which is in his possession belonging to another till certain demands of the person in possession are satisfied. (Grose, J., in 'Hammond v. Barclay,' 2 East, 227.) The definition therefore includes possession (in some sense) by the party claiming the lien; and an unsatisfied demand by him against the owner of the property.

It has been said that 'liens only exist in three ways; either by express contract, by usage of trade, or where there is some legal relation.' (Bayley, J., 1 Ba. and Ald., 582.)

When lien arises by express contract, it is simply mortgage, pawn, or pledge, which are then the more

appropriate terms; or it is an agreement (such as may exist in the case of principal and factor) that goods intrusted by one person to another for the purpose of sale, or for some other purpose than pledge, may be retained by the party intrusted with them as a security for any debt or balance due to him from the other; or it is an agreement that he may retain the proceeds of things intrusted to him to sell, for the same purpose.

Where two parties have so dealt with one another that one has claimed and the other has allowed the right of lien in respect of any their mutual dealings, lien may exist in all cases of like dealings between them, if there be no verbal or written agreement to the contrary. The acts of the parties are here the evidence of the contract.

The 'lien by usage,' and that 'where there is some legal relation between the parties,' belong to one class, and are not distinguishable. They are both included under liens which arise from implied contract. The 'usage of trade' is merely evidence from which contract is to be implied: parties who mutually act in conformity to a custom, have in effect, though not in form, made a contract. The term 'legal relation' is only another mode of expressing the mutual rights and duties of the same parties, who by their acts have brought themselves within the limits of a custom, and so given evidence of an intention to make a contract. Thus an innkeeper has a lien upon the horse of his guest which he takes into his stable to feed.

Lien, unless there be an express contract, or a custom to the contrary, must from its nature be *particular*, that is, must have reference to a particular transaction and to a particular thing. When it is *general*, that is, where the right to retain a particular thing is not limited to a particular transaction, but exists with respect to other transactions also, there must be express contract, or the dealings of the parties must be such as to create that implied contract which arises from acts done in conformity to well-known usage.

Lien may be lost by voluntarily parting with the thing, by express agreement, or by agreement to be implied from acts. In general, when a person has a lien for a debt, he waives it by taking security for the debt.

In Equity, the vendor of an estate, though he has executed a conveyance and parted with the possession without being paid, still has his estate as a security for such part of the purchase-money as is unpaid. This security is generally, though not with strict propriety, called the vendor's lien. The ground of this so-called lien lies in the nature of the contract: one party contracts to give land for money, and the other contracts to give money for land; and both parties must perform their engagement.

The practical questions which arise under the general doctrine of lien are numerous, and sometimes not easy of solution; many of them are of the greatest importance to the mercantile community. The chief cases in which lien exists may be referred to the law of Agent, Attorney, Bailment, Carrier, and Factor. Montagu's work 'On Lien' contains a collection of a considerable number of particular instances. The law of lien is known in Scotch law under the name of *Retention*; and the practical results of the doctrine are almost the same in both countries.

LIERRE. [ANTWERP.]

LIESTALL. [BASEL.]

LIEUTENANT, any officer who discharges the duties of a superior in his name and during his absence, and who acts immediately in subordination to him when he is present.

Thus, in military affairs, the lieutenant-general and the lieutenant-colonel respectively superintend the economy and the movements of the army and the battalion under those who hold the chief command. For many years past, however, the lieutenant-colonel has been the officer actually in command of a regiment—the colonelcy having gradually become a sinecure appointment. The lieutenant of a company is also immediately subordinate to the captain, in whose absence he has the same powers. In the British service the lieutenants of the three regiments of foot-guards have the rank of captain: in the royal regiment of artillery, the royal corps of engineers and marines, there being no ensigns, the subaltern officers were formerly distinguished as first and second lieutenants; but they are now all styled lieutenants—the juniors receiving only the pay of a second lieutenant. The pay of a lieutenant in the army varies from 10s. 4d. a day in the Life Guards to 6s. 6d. in the line.

A lieutenant in the royal navy takes rank as a captain in the army, and the number appointed to ships of war varies with their rate. Their full pay is 10s. per day, and their half-pay ranges from 4s. to 7s., according to their length of service. At least six years' service are required before a lieutenancy can be obtained in the navy.

LIEUTENANT-GENERAL. [GENERAL.]

LIEUTENANT, LORD. [LORD LIEUTENANT.]

LIEUVIN. [CALVADOS; EURE.]

LIFE. Organic matter, in which alone the phenomena of life are cognizable to our senses, is distinguished from common or inorganic matter by several peculiarities of composition and structure. Twenty elementary substances occur in organic matter, viz., oxygen, hydrogen, nitrogen, carbon, phosphorus, sulphur, iodine, bromine, chlorine, fluorine, potassium, sodium, calcium, magnesium, silicon, aluminum, iron, manganese, copper, and lead. Of these the first four, on account of their universal presence in organic matter, have been called organic elements. But although the elementary substances of which organic matter is composed are the same as those of common matter, their mode of combination is peculiar. In minerals, the elements are generally united in pairs, or according to a binary mode of combination; but in organic matter, three at least, and usually four elementary principles, are combined in each simplest substance or proximate principle. In organic compounds again, the elements are not generally united in any simple ratio one to another, as 1 atom of one to 1, 2, or 3 of another, as in inorganic bodies, but several (as 10 or 12 of one) are united with several of each of the others to form one compound atom.

In respect of structure, it is observed that all organic bodies, plants as well as animals, have a more or less rounded and cylindrical, branched or membered form, bounded by curved lines, and by convex or concave surfaces very distinct from the crystalline, the only regular form of inorganic matter.

All the parts of an organic body are, both in their origin and in their continuance, more or less dependent upon one another. In their original formation, the production of one part induced that of another; and, when formed, the action of one influences the actions of all.

The maintenance of the living being, during a certain length of time, by the mutual changes which take place between it and the external world, is the most general phenomenon observed in organic bodies during life. It is a compound process, consisting—1st, Of the reception of materials from the external world as nutriment, which is taken up by absorption and carried on by a peculiar motion in vessels, or through the interstices of the tissues; 2nd, Attraction of aeriform substances from without, and separation of other aeriform substances from within, constituting respiration; 3rd, Conversion of the nutriment and aeriform substances imbibed into the peculiar fluids of the body—assimilation; 4th, The motion of these fluids through the body by a circulation or other means; 5th, Conversion of the fluids into a solid form, or the combination of them with the solids, so as to maintain the peculiar properties of the latter, constituting nutrition properly so called; 6th, The preparation and separation of fluids of peculiar kinds from the assimilated fluids, or the formation of secretions. These processes, which are called the nutritive functions, occur in a more or less distinct manner in all living bodies, plants, as well as animals, and are essentially characteristics of Life, to which nothing analogous is ever observed in inorganic bodies.

LIFE ANNUITY. [ANNUITY.]

LIFE, DURATION OF. [MORTALITY, LAW OF.]

LIFE-BOAT; LIFE-BUOY; LIFE-PRESERVER. Many ingenious plans, more or less practicable, have been proposed for saving from drowning those who may be in peril by shipwreck or otherwise. These contrivances may be classed as *Life-Boats* and *Life-Buoys*, or *Life-Preservers*.

Life-Boats.—A life-boat is a boat constructed with great strength to resist violent shocks, and at the same time possessing sufficient buoyancy to enable it to float, though loaded with men and filled with water. Such boats are maintained at most of the ports of this kingdom, always ready to put to sea when vessels are seen in danger of shipwreck, and provided with means for being conveyed to the shore, and launched as rapidly as possible. As early as the year 1785, a patent was granted to Mr. Lukin for a life-boat with projecting gunwales and hollow cases or double sides under them, as well as air-tight lockers or inclosures under the thwarts: these contrivances increased the buoyancy of the boat, and the air-tight cases under the gunwales, by their weight when raised above the surface of the sea, and their resistance, when depressed beneath, greatly prevented rolling. Mr. Lukin's boat was strong and buoyant, but it was liable to be disabled by having the sides staved in. This defect was obviated in Mr. Greathead's boat, which was invented soon after; its prevailing feature was that of being lined inside and outside with cork. His boat was instrumental in saving the lives of 300 persons in five years, near Tynemouth.

From time to time other inventors came forward with improvements and plans. Boats of various powers and dimensions were constructed, but some

were found to fail in the moment of trial. In 1850 the late duke of Northumberland offered a prize of 100 guineas for the best model of a life-boat. The

Fig. 1.—Sheer Plan.

committee appointed to adjudicate upon the merits of the designs sent in laid down the following among the requisite qualities:—A life-boat must be good in

rowing, good in sailing, good in launching through a surf; it must have small internal capacity for water, and easy means of riddance of any it may receive;

Fig. 2.—Deck Plan

it must be buoyant, and possess self-righting power; it must be adapted for beaching, light for transport along the shore, roomy for passengers, and possess good access to stem or stern, &c. The model which was found to possess the greatest number of these good qualities was one sent in by Mr. Beeching, of Yarmouth, to whom the prize was consequently awarded. Mr. Peake, the master shipwright at Portsmouth, who was one of the committee, designed a boat which comprised many of the features of the competitive boats, and added others suggested by his experience. This boat, gradually improved in later years, is the one which now constitutes the recognized English model, and is adopted, to the exclusion of all others, by that highly useful society, 'The National Life-boat Institution.' Many boats of the same kind have also been sent to foreign countries.

In the annexed cuts we give plans and sections, showing the construction of the life-boats of the Institution. The boats are each 33 feet in length, and 8 feet in breadth. In fig. 1 the general exterior form of the boat is shown. The dotted lines indicate the position and dimensions of the air-chambers; the relieving tubes, with self-acting valves, for allowing the water which may enter to escape; and ballast. The festooned lines represent exterior life-lines attached round the entire length of the boat, to which persons in the water, by stepping on them, may climb into the boat; the two central lines are festooned lower than the others, to be used as stirrups, so that a person in the water, by stepping on them, may climb into the boat. In fig. 2, A represents the deck, B the relieving tubes (six inches in diameter), C the side air-cases, D the end air-chambers, E ballast, F ventilators to admit of a free current of air

under the water-tight deck, G ventilator to receive pump. In fig. 3 the exterior form of transverse sections, at different distances from stem to stern, is shown.

Fig. 4 represents a midship transverse section, A being sections of the side air-cases, B the relieving-tubes, of the same depth as the space between the deck and the boat's floor; C, C, C, are spaces beneath the deck, 9 feet in length, placed longitudinally, at the midship part of the boat, with solid chocks of light wood, or cases

Fig. 3.—Body Plan.

Fig. 4.—Midship Section.

packed with cork, forming a portion of the ballast; D is a ventilator, having a pump fixed in it, by which any leakage can be pumped out by one of the crew whilst afloat.

The chief peculiarities of the boats of the 'National Life-boat Institution' are (1), that they are rendered unsubmergeable by attaching to them, chiefly within board, water-tight air-cases, or fixed water-tight compartments under the deck; (2) the capability of self-discharging in a few seconds any water which may be shipped by the breaking over of a sea, or by a boat being suddenly thrown on her beam ends. This is accomplished by tubes fitted with self-acting valves, which open downwards only, so that they

will allow any water shipped to pass out; whilst none besides a trifling leakage can pass upwards through them. The greater the quantity of water within, the faster it will run out. (3) The power of self-righting—which is accomplished chiefly by attaching an iron keel, weighing from 4 cwt. to 8 cwt. When the boat is upset, she is floated unsteadily on the two air-chambers at the bow and stern, whilst the heavy iron keel and other ballast being then carried above the centre of gravity, an unstable equilibrium is at once effected, and the weight of the iron keel falling over on one side, immediately restores the boat to her proper position.

Most of the life-boats in the United Kingdom now belong to, or are under the superintendence of, the National Life-boat Institution, a society well deserving generous support. It was incorporated by royal charter in 1824, and from that time to the end of 1865 it had been the means of saving several hundred vessels and no less than 14,992 lives. It has now 153 boats stationed at those parts of the coast where experience has proved they will be most useful. The following extracts from the rules will give a good idea of the plan of operations pursued by the society:—

‘Each life-boat to have a coxswain superintendent, with a fixed annual salary of 8*l*., and an assistant coxswain with a yearly salary of 2*l*.

‘The life-boat to be regularly taken afloat for exercise once every quarter, fully manned and equipped, so that the crew may be familiar with her qualities and proper management. On every occasion of exercise, the men are to be paid 5*s*. each in stormy weather and 3*s*. each in fine weather; and on every occasion of going off to a wreck to save life, each man of the crew to receive 10*s*. by day, and 1*l*. by night. These payments to be doubled on occasion either of extraordinary risk or of long exposure.

‘The life-boat to be kept on her carriage, in the boat-house, with all her gear in her ready for use. Signals are agreed upon for calling the life-boat’s crew together; and immediately on intimation of a wreck, or vessel in distress, the coxswain is to muster his crew, who are to put on their life-belts, launch his boat, and proceed to her assistance.

‘The local committee to make quarterly inspection, and report to the Institution as to the behaviour of the boat during exercise, pointing out any defect that may be remedied, and offering any suggestion that may conduce to the efficiency of the service.’

The expense of a life-boat station is 620*l*. Its cost is made up as follows:—

Life-boat and her equipment, including	
life-belts for the crew, ...	£320
Transporting-carriage, to take the boat	
from the boat-house to the sea, ...	100
Boat-house (average cost), ...	200
Total, ...	£620

The crews are formed by the coast-guardsmen, fishermen, and sailors on the coast, and are unflinching, brave, and unselfish in the hour of peril. In 1865 the Institution expended 21,374*l*. on its various life-boat establishments on the coasts of England, Scotland, and Ireland. For the services rendered in saving lives since its formation 82 gold medals, 751 silver medals, and 21,111*l*. in cash, have been paid

in rewards. The Institution also expended 128,859*l*. on its life-boat establishments from 1824 to 1865.

Most large vessels now carry one or more life-boats; but as the size of the ordinary life-boat renders it inconvenient for stowage on shipboard, a collapsing boat is used, the sides of which are connected by hinges, and which are thus readily expanded. It possesses great strength, and many of the advantages of the ordinary life-boat.

Life-Buoy or Life-Preserver.—Anything lighter than water, used as a means of personal safety on account of its buoyancy, may be considered a life-buoy. Various substances have from time to time been tried for this purpose, but cork is now most generally preferred; and the buoy which has of late years most successfully won its way into the favour of seamen consists of a kind of hoop, composed of slices of that material, about 32 inches in diameter and 6 inches in width, with a thickness of about 4 inches. It contains altogether about 12 lbs. of cork, is compactly covered with painted canvas, and furnished with lines, to afford a more convenient hold, and under ordinary circumstances will support at least four men. In fact, it has been estimated that one pound of cork is sufficient to support a man of ordinary size and make. Many varieties of life-buoys have been made of india-rubber inflated with air, including mattresses, jackets, and waistcoats, but the general objection to them is that they are liable to be rendered altogether useless by being punctured or torn, and are also often subjected to decay by being put away while damp. The crews of the National Life-boat Institution wear a life-belt composed of cork, and tied over the shoulders and around the waist. Many lives have been saved by this apparatus, as it is quite sufficient to keep a man afloat; and, on the other hand, it does not at all interfere with the action of the arms either in swimming or rowing. The Society has of late years endeavoured to procure the more general adoption of these belts in merchant vessels; and although sailors were at first prejudiced against them, they are every year becoming more generally used, as it is felt it is no imputation on the courage of a brave man that he seeks to protect his life.

Empty casks, well bunged up, form good life-buoys; and a patent life-raft consists of a square frame buoyed up by a cask at each corner. A 36-gallon cask is quite sufficient to sustain ten men under ordinary circumstances, and in tolerably smooth water. Frames of bamboo and inflated goat and seal skins are used as life-preservers in some foreign countries, and in China gourds are employed for a similar purpose.

LIFE GUARDS. A military term, applied to those squadrons of cavalry which act as the body-guard of a sovereign prince. In every nation the sovereign has invariably been protected by some such special force. In England, the present cavalry establishment was formed by Charles II., shortly after his restoration, and became, as Macaulay says, the germ of that great and renowned army which has, in the present century, marched triumphant into Madrid and Paris, into Canton and Candahar. The Life Guards, who now form two regiments, were then distributed into three troops, each of which consisted of two hundred carabineers, exclusive of

officers. The privates were well paid, clothed in a superb uniform, and designated as gentlemen of the guard. The Blues received their name from their blue coats and cloaks. The Dragoons, now included in the heavy cavalry, were originally light horsemen. The Scots Greys, a regiment raised after the Union, received their appellation from their uniform, but are now mounted on gray horses. The *pay per diem* of a lieutenant-colonel in the Life Guards is 29s. 2d.; of a major, 24s. 5d.; of a captain, 15s. 1d.; of a lieutenant, 10s. 4d.; of a cornet or second lieutenant, 8s.; and of an adjutant, 13s. In the Dragoons the emoluments are about four-fifths of these amounts. A lieutenant-colonel's commission in the Life Guards is valued at 7250*l.*; a major's, 5350*l.*; a captain's, 3500*l.*; a lieutenant's, 1785*l.*; and a cornet's, 1260*l.* Each of the Life and Horse Guard regiments now consist of 343 men, 64 non-commissioned officers, and 33 commissioned officers, making a total for the three regiments of 1320 men of all ranks.

LIFE INSURANCE. [INSURANCE, LIFE.]

LIFE-PRESERVER, an ingenious apparatus, invented by Captain Manby, for rescuing persons from shipwreck. It consists of a long rope, attached to a shot, which is discharged from a mortar over the stranded vessel. A communication having been thus effected between the shore and the wreck, little difficulty remains in rescuing the passengers by the means of boats, or otherwise. Connected with this apparatus are night-balls, which are provided with hollow cases of thick pasteboard, with a fuze and quick match, and charged with sufficient powder to inflame them. The fuze is so graduated that the shell explodes at the height of 300 yards; and the balls spread a brilliant light for about a minute, and give a clear view of every surrounding object. This apparatus has been the means of preserving hundreds of lives.

LIFERENT, in Scotch law, is the right to use and enjoy a subject during life, without wasting its substance, Ersk., 'Inst.' II., 9, 39. Its origin is attributable to the servitude of *usus fructus* in Roman law, from which it differs rather in the nature of the subjects of which it may consist than of the use permitted of them. In Scotch law the subject of liferent may be either heritable subjects or money. The proprietor of the subject is named the *fiar*, and the person enjoying the use of it the *liferenter*. There are two liferents established by the mere disposition of the law, of which the one called *tora* consists in the right of a widow who has produced a living child to the liferent of one-third of the heritable estate of which her husband died *fiar*; and the other, called *courtesy*, is the right of the surviving husband of an heiress, when the marriage has produced an heir to the estate, to a liferent of the whole heritable estate of his wife to which she may have succeeded by inheritance.

LIGATURE, in modern music, a binding, indicated by a curved line, . If two notes of the same pitch are thus joined, only the first is to be struck, but the second to continue its full time. *Ex.*—

In vocal music all the notes which are set to one syllable are bound together.

LIGHT. It was once generally assumed that light consists of particles emitted from a luminous body; and this hypothesis may yet be conveniently adopted in explaining many of the phenomena of light and vision. A series of particles proceeding in a line constitute what is called a *ray* of light; and a small number of rays parallel to one another, or diverging from a point, form a *pencil* of light. In vacuo, and also in a uniform medium, the rays are conceived to be straight lines; but at the surfaces and in the interiors of bodies, light suffers modifications, which generally produce deflections from the rectilinear direction.

The rays being supposed to diverge in every direction from a luminous object, it follows that, if a small cone of rays were intercepted by any plane surface, which may be considered as part of the concave surface of a sphere having the radiant point for its centre, the intensity of the light on the surface will be inversely proportional to the square of its distance from that point. It is also evident that two luminaries are equal in absolute light when, being placed at equal distances from, and in similar situations with respect to a given smooth white surface, or two equal and precisely similar white surfaces, they illumine it or them equally. This appears from Plate 1, fig. 1. ABCD is a section of a small rectangular box open at both ends, and blackened within. On the inside, inclined at angles of 45° to its axis, are placed two rectangular pieces of plane looking-glass, FC, FD, exactly alike, and fastened so as to meet at F, in a narrow slit, EFG, covered with a slip of fine tissue paper. To compare the powers of the lights, PQ, place them at such distances from each other and from the instrument between them, that the light from every part of each shall fall on the reflector next it, and be reflected to the corresponding part of the paper, EF or FG. The instrument is then to be moved nearer to the one or the other, till the paper on either side of the division F appears equally illuminated.

Certain astronomical phenomena (aberration, and the eclipses of Jupiter's satellites) prove that the propagation of light through space is not instantaneous; and that it takes place, in round numbers, at the rate of 192,000 miles per second. The phenomenon of aberration illustrates this. Let a ray of light from a star, S (Plate 1, fig. 2), be received on a small screen, A, having an extremely minute opening, A, in its centre; and let that ray which passes through the opening be received at any distance, AB, on a screen, B, perpendicular to its direction; and let B be the point on which it falls. If, then, we join the points AB by an imaginary line, that line will be the direction in which the ray has really travelled, and will indicate to us the direction of the star. But let us suppose the apparatus carried along in the direction AC, BD, the ray passing through the aperture at A will now have the appearance of having fallen from *a*, in the direction *aB*.

By investigations purely mathematical it has been found that, if a small object be placed between two lights of different intensities, the point at which the object receives the least illumination from both is at a distance from either light directly proportional to the cube root of the intensity of that light, and inversely to the sum of the cube roots of both inten-

sities. And when a given object is enlightened by a luminous surface of small but sensible size, the degree of its illumination is proportional to the area of the luminous surface multiplied by the intensity of its illuminating power, and divided by the square of the distance of the surface illuminated. (See Plate 1, fig. 3.)

A convenient method of comparing the intensity of the light from two luminaries is illustrated by fig. 4, Plate 1. Before a screen, CD, of white paper in a darkened room place a blackened cylindrical stick, S, and let the flames *Ll* be so placed as to throw the shadows, AB, of the stick on the screen. Then move the lights till the two shadows appear of equal intensity. Their total illuminating powers will be in the direct ratio of the squares of their distances from the screen.

Again, if light from any luminous object pass through a small aperture and fall upon a screen in a darkened room, there will be formed an inverted image of the object (Plate 1, fig. 5), its magnitude being inversely proportional to the square of the distance of the object: now the intensity of light on the image, which is inversely proportional to the square of that distance, is also inversely proportional to the magnitude of the image; and it follows that the brightness of the image is constant, whatever be the distance of the luminous object. The eye is such a darkened room, and therefore a luminous object should appear of equal brightness at all distances; but the absorption of light in the atmosphere causes the greater dimness of distant objects. Again, in fig. 6, let A be a small aperture through which light falls from the sun, S, on the screen, B, in which there is also an aperture through which the light passes to another screen, C; it is evident that it will then not dilate itself as at B, and form an image of the whole sun, but only an image of that very minute portion of it which corresponds to the space occupied in its images on the first screen by the hole made there.

If a body on which light falls be unpolished and opaque, a portion of the light enters into it for a small depth, and is there partially absorbed; the complementary portion is scattered in all directions; the surface therefore becomes itself, to that extent, a source of light, but the composition of the differently coloured rays may be widely different from that of the incident light. When the body on which parallel rays of light fall is polished, the rays which do not enter the body are reflected from it principally in one direction; this, for a single ray, is in a plane passing through the ray perpendicularly to the reflecting surface (this is called the plane of reflection). By experiments made for the purpose, it has been found that the angle which the reflected ray makes with a line perpendicular to the surface is equal to that which the incident ray makes with the same line. This is an important law concerning the reflection of light, and it may be equally well accounted for on the theories of emission and undulation.

The *deviation* of a ray of light, after it has undergone any alteration in its course by the action of media, is the inclination of the primitive and final directions of the ray taken in the sense in which they are moving. This deviation by one reflection

on any surface is the supplement of double the incidence, or is the double of the inclination of either ray to the medium.

When there are successive reflections, the inclination of the plane of the first to that of the last reflection is the *deviation in plane*; the last ray being then in a different plane from the first, the first kind of deviation, or that of direction, is the angle between the first ray produced beyond the incident point (which is the course the ray would have pursued if unreflected), and a parallel to the last ray drawn from the same incident point.

When light is reflected by two parallel planes, there will be neither deviation in plane nor in direction; more generally there will be no deviation in plane when the first incident ray is in a plane perpendicular to the intersection of the two reflecting planes.

When light diverging from any luminous point falls on a plane reflecting surface, it will, after reflection, diverge accurately from a point similarly situated at the opposite side of the mirror. Let S be the luminous point, DE the mirror; draw SA perpendicular to the mirror, and produce it until $As = AS$; let SB be an incident ray, join sB, and produce it to C; then it is evident that $\angle SBA = \angle sBA = \angle CBE$. Now BC, being in the normal plane, SAB, and making, with the normal BF, an angle, CBF, equal to the angle, SBF, of incidence, must therefore be the reflected ray. The position of *s* being independent of that of B, the point of incidence, it

follows that every other reflected ray, *bc*, will diverge from the same point. Thus the reflected light will appear to an eye, *c*, as if proceeding from a point, *s*, behind the mirror similarly situated with S.

Hence, if any body, PQ, be placed before a mirror, DE, the light which emanates from P will appear after reflection to proceed from the similarly situated point, *p*, behind the mirror, and thus an *image*, *pq*, exactly similar to the body, PQ, will be seen by looking at the mirror; the common looking-glass is a familiar example.

When light diverging from a point falls on a surface, after reflection it generally does not again converge to a point, or diverge from one accurately, but each infinitesimal pencil after reflection con-

verging to or diverging from a point, the locus of all such points forms an illuminated surface called a caustic by reflection, or catacaustic. This may be well illustrated by the following simple experiment by Sir David Brewster, shown in Plate 1, fig. 7:—Bend into a concave form a narrow strip of polished steel, and place it upright on a sheet of white paper. If this is held so that the plane of the paper passes nearly through the sun, the caustic will be seen brightly traced on the paper.

When light is incident on a transparent medium of greater density than that of the medium in which it originally moved, a portion of the light enters the medium, and then proceeds generally in one straight course in the plane of incidence, but not in the original direction, having a deviation *in course* though not *in plane*; and sometimes, as in certain crystallized media, it splits into two rays, one in the plane of incidence as before, the other in a plane determined by the nature of the crystal. The same phenomena take place when light passes from a dense to a rarer medium, except that in this case the whole of the light may under a certain incidence be totally reflected.

This alteration of the path of light passing from one medium to another, which is familiarly observed in the apparently bent form of a straight stick partially immersed in water in an oblique direction, is called refraction, as in Plate 1, fig. 8, where ACB is the refracting surface, PCp the perpendicular to it at the point of incidence C, SC the incident and Cs the refracting ray. That portion which is in the plane of incidence is called the *ordinary ray*, and the other portion, which occurs in the double refraction of uni-axal crystals, is called the *extraordinary ray*. We shall first attend to the laws of single refraction.

Let NPC represent a solar beam in vacuo, and

incident at C on a transparent medium (as water), to the surface of which DCE is normal. When the medium is fluid, place a graduated circle, DSE, in the plane of incidence, with its centre at C; a portion of the light will be reflected in the direction CL, and another entering the medium will be refracted in the direction CR. If uninfluenced by the medium, its direction would have been CS. The angle, RCE, is the angle of refraction, DCN or ECS of incidence, and SCR of deviation. The arcs DP, DL, are equal by the law of reflection, and if we compare the arcs DP, ER, their sines will be found in a constant ratio, depending on the nature of the medium, but independent of the angle of incidence. Thus, if I be the

angle of incidence, and R that of refraction, the two are connected by the simple relation $\sin I = \mu \sin R$. The constant μ peculiar to the medium is called its *index of refraction*.

The reflection which accompanies refraction may be familiarly illustrated by filling a glass with water, and holding it above the level of the eye (fig. 9, Plate 1) in the direction Eac, when we shall see the whole surface shining like polished silver, and a spoon, ACB, immersed in it will be reflected on the surface as on a mirror. In this case, almost the whole incident light is reflected. A ray of light refracted through a medium with parallel plane surfaces, will have its final direction after both refractions the same as before entering the medium. See Plate 1, fig. 10, in which ABDF is the medium, and SET the ray of light. Again, a ray SB, fig. 11, incident on a compound medium consisting of two media, ACDF and DFGI, of different refractive indices, and with parallel external surfaces, will emerge in a direction HT, parallel to the incident ray. Pp, Qq, and Rr, show the amount of refraction in each medium.

The formation of foci and images by reflection and refraction are described in OPTICS; and the instruments constructed to take advantage of the properties of light, in MICROSCOPE; MIRROR; OPTICS, PRACTICAL; TELESCOPE.

Light, as we receive it from the sun or from other sources, as a star, a fire, a candle, &c., appears to the senses as a simple element; and, judging from our early impressions, we might consider the peculiar colours of bodies as inherent in those bodies; but we are enabled to trace the immediate cause of the colours of bodies, whether permanent or transient, by the analysis of light furnished by the well-known experiments of the glass prism.

The triangular prism used for this purpose is a solid, terminated by two equal and exactly similar triangles, and having besides three plane faces of a rectangular form, contained by the sides of the triangles and by right lines or edges joining corresponding angles of the two triangular bases above mentioned; and any imaginary right line within it parallel to these edges around which the prism is capable of revolving is called the *axis of the prism*.

In the annexed figure the triangle, BAC, represents a section of the prism parallel to its basis or perpendicular to its axis. DE we shall suppose to be a ray or exceedingly narrow beam of solar light passing into a darkened room through a small circular hole in a shutter, and incident on the prism at E; this ray of white light enters the prism at that point,

and having undergone refraction by the dense medium of the glass, no longer proceeds as a simple ray EF , but is *dispersed* or divided into various rays of different colours over the space represented in the figure by $f'EF$, and emerging at $f'F$ from the prism, undergoes another refraction, such that the portion, $f'g$, of the ray proceeding from f' is still more refracted than the portion, $F'G$, from F' , since the sines of the angles of incidence and refraction being in a constant ratio, that portion will be most refracted which has the greatest incidence: let now this dispersed beam, gf' , $F'G$, be intercepted by a screen or wall, $P'K$, and from which extraneous light is as much as possible excluded, we shall then find the elongated space or spectrum, $g'G$, brilliantly painted over with tints passing gradually and insensibly from deep red to an attenuated violet, in the following order, as described by Newton, and since very generally concurred in—red, orange, yellow, green, blue, indigo, violet.

Suppose, now, that a small orifice, O , is made in the screen at some point of the spectrum, so that rays of any particular colour, green for example, may be transmitted through it; and let the transmitted portion be again subjected to refraction through another prism, this beam being supposed very small, to ensure its purity or near uniformity of colour. It will not, after refraction, be again decomposed, or undergo any alteration of colour, except in respect to brilliancy, arising from absorption by the second prism: thus showing that light incident on the first prism, when once decomposed into homogeneous elements by refraction, is then, at least by refraction, not further decomposable.

If the original prism, BAC , be turned gradually round its axis, preserving always to the incident light the same refracting angle, A , the spectrum, Gg , may be made to descend towards K ; but after arriving at a certain point where the deviation, that is, the inclination of DE produced to FG , is a minimum, it then reascends, and it is usual to make the chromatic experiments in this definite position of minimum deviation. This occurs when the position of the prism is such that the angles of incidence and emergence, or their complements DEB , GFC , are equal to one another. The course of a ray after the second refraction differs according to the media from which it passes, and into which it enters. Let the ray, S (Plate 1, fig. 12), pass through a prism denser than the surrounding medium, and the ray is bent towards the thicker part of the prism. If the prism be rarer than the medium the contrary is the case (fig. 13). The same state of things is also illustrated by figs. 14 and 15.

We have seen that compound light, the sun's, for example, may be decomposed into its homogeneous constituent rays by refraction through a transparent prism. Conversely it may be recomposed into light similar to the original, merely by making the rays, thus separated, by another refraction to occupy the same place. This may be effected by placing a prism of exactly similar material and form to that already used, with its refracting angle turned in a direction opposite to that of the former, so that the near faces of both prisms may be parallel; for the rays entering the second prism are in the same condition as if we supposed their direction inverted, that they may repossess through the first; and therefore

they emerge in a similar compound ray with the original, which may also be easily confirmed by experiment.

The rays issuing from the second face of the refracting prism may also be collected by means of a double convex lens, so as all to meet very nearly in its principal focus, where, if the image be received on a sheet of paper, the original compound light will be reproduced.

Many of the prismatic colours may be imitated by mixing colours taken as in the spectrum of greater and less refrangibility, as orange from red and yellow, &c., but such compound colours are not identical with the homogeneous light of the same colour, being immediately decomposable when viewed through a prism.

It would be difficult, if not altogether impracticable, to judge of the *dispersive powers* of transparent media by measuring the length of the spectra which they produce in a prismatic form, in consequence of the indefiniteness of their *termini*. Fortunately, Nature has herself furnished a scale of definite limits in the beautiful discovery made by Wollaston and Fraunhofer of the existence of dark spaces, bands transverse to the length of the spectrum, and now generally designated Fraunhofer's lines.

These bands are best observable by forming the spectrum of a luminous line instead of a point, by means of a prism of great purity, and viewing it through a telescope of good magnifying power, though some of them may, when carefully pointed out, be recognized by the unassisted eye, and after one recognition are in future easily found.

Substances which have not a great difference of refractive powers possess frequently very different dispersive powers, and the angular dispersion by a medium is not proportional to the angular deviation, and therefore by a system of prisms, two or more, white light incident on the first may be reproduced from the last, though on the whole refracted from its original direction. Such a system is called *achromatic*.

Conversely, by forming an achromatic system experimentally, where the angles of the prisms are small, and in the position of minimum deviation, if the dispersive power of the material of one of them be taken as a standard, that of the other may be readily obtained, the dispersion being measured

by $\frac{\delta \mu}{\mu - 1}$, μ being the index of refraction, and $\delta \mu$

the difference of its extreme values for any class of rays.

The rainbow is a beautiful natural exhibition of the dispersion of light into the spectral colours. [RAINBOW.]

Much has of late years been done in examining the nature and properties of light, and great advances have been made in the knowledge of its actinic properties. One of the most important of all modern discoveries on the subject is that by Dr. Faraday, who made a ray of polarized light rotate under the influence of an electric current. The analysis of light has recently led to the determination of certain of the substances existing in the sun.

LIGHT, BAROMETRICAL, is a luminous appearance in the vacuum over the mercury in some

barometers. It appears to be an electrical phenomenon, but we are not aware that any satisfactory explanation has been given of it.

LIGHT, CHEMICAL AGENCY OF. There are several cases in which light exerts direct chemical agency without its being referrible to the heat which usually accompanies it when intense. Thus, if a mixture of equal volumes of chlorine and hydrogen gases be kept in the dark, no combination takes place between them; but in the light of day they unite slowly, and form hydrochloric acid gas; while if exposed to the direct solar rays, the combination occurs instantaneously, and with loud explosion. Chlorine gas and oxide of carbon, when mixed, unite by the direct action of the sun's rays. If colourless nitric acid be exposed to the sun's rays, it becomes yellow, and afterwards red, and a quantity of oxygen is liberated by the partial decomposition effected by the solar rays. The action of light on the chloride of silver is very remarkable, and it occurs very quickly. This substance, as long as it is kept from the light, even though it be exposed to heat, remains perfectly colourless; but the sun's rays, and even diffused daylight, by their peculiar action, blacken it speedily. Chemistry presents many such examples as these.

LIGHT-BALLS, for military purposes, are hollow cases, either spherical, or in the form of cylinders terminated at each extremity by a hemisphere: they are filled with a combustible composition, and being thrown by night in a burning state from mortars, or in some cases from the hand, they serve to discover the working parties or troops of the enemy. The composition consists of pulverized saltpetre ($6\frac{1}{2}$ lbs.), pulverized rosin ($1\frac{1}{2}$ lbs.), ground sulphur ($2\frac{1}{2}$ lbs.), and linseed oil ($\frac{1}{2}$ lb.). The balls are propelled from mortars varying from $4\frac{3}{4}$ to 10 inches calibre, and correspond to the size of the mortar employed. Spherical cases of paste-board or canvas, filled with a composition which, while burning, emits a great quantity of smoke, are frequently discharged from mortars in order to conceal a movement of troops from the view of, or to suffocate the enemy: these are called *smoke-balls*.

LIGHTFOOT, JOHN, born 1602, died 1675, one of those English divines who belong peculiarly to the class called *commentators*. His works are collected in two large folio volumes. He was the son of a clergyman at Uttoxeter in Staffordshire, studied at Cambridge for the church, was ordained, and settled early in life on the living of Stone in his native county.

In the disturbed times he took part with the Presbyterians, became a member of the assembly of divines, accepted the living of St. Bartholomew beside the Exchange, and was made master of Catherine Hall by the parliamentary visitors of the University of Cambridge. He had also the living of Great Munden in Hertfordshire, which was presented to him in 1644. On the restoration of King Charles II., Dr. Lightfoot complied with the terms of the Act of Uniformity.

LIGHT-HORSE, cavalry lightly armed, and intended for active service and desultory warfare. Of this description are the light dragoons, mounted yeomanry, fencible cavalry, &c.

LIGHTHOUSES are buildings erected along the sea-shore, or upon rocks, from which lights are

exhibited at night for the direction of mariners. Floating lights perform a similar office, being shown from the masts of vessels moored in certain positions, generally as beacons to enable ships to avoid shoals or sunken rocks in the estuaries of great rivers. The most celebrated lighthouse of ancient times was that erected about B.C. 283, in the reign of Ptolemæus Philadelphus, on the island of Pharos opposite to Alexandria. [ALEXANDRIA.] It is from this building, or rather from the island on which it stood, that lighthouses have in many countries received their generic name of Pharos. This light tower endured for 1600 years. The oldest existing is that at Corunna, in Spain, said to have been erected in the reign of Trajan, and now fitted with one of the finest modern light apparatus. The celebrated Colossus of Rhodes has also been supposed by some to have had a light at its summit, but on no certain evidence. Various ruins of towers on the coasts of Great Britain, and on the shores of Europe, may be the remains of ancient lighthouses. The most celebrated lighthouses of modern times are the Bell-Rock Lighthouse, opposite to the Frith of Tay; the Eddystone Lighthouse, opposite to Plymouth Sound (see Plate 1); the Skerry-Vore Lighthouse, completed in 1844, on one of the rocks of a dangerous reef about 14 miles S.W. from the island of Tiree, on the coast of Argyleshire; the Tour de Cordun, near Bordeaux; the Fastnet-Rock Lighthouse; and the Maplin Sands Lighthouse (see Plate 3). [BELL-ROCK; PLYMOUTH; SKERRY-VORE.]

The erection of lighthouses in this country has not proceeded upon any systematic plan, but in every instance they have been constructed simply because of the disastrous losses that had occurred for want of them. The character of the buildings in which the beacon-lights are placed is dependent on their situation. They may be placed on lofty cliffs at a considerable height above the sea, as at Flamborough Head and the North and South Forelands, in which case the building itself need not be lofty, but only of such peculiar shape and colour as to make it conspicuous from the sea by daylight, and to make it easily distinguished from the dwelling-houses or other buildings in its neighbourhood. Or they may be situate on low promontories but little above the sea level, as on the flat beds of shingle at Orfordness and Dungeness, where they must be raised to a considerable elevation, that the light by night, and the building by day, may be discernible at long distances from the land. Or they may be fixed on the isolated and even sunken rock, as the celebrated Eddystone in the English Channel, in which case the whole skill and science of the engineer must be expended, not only on their foundations, but on their entire structure, to enable them to stand the mighty shocks of the waves. Or, lastly, they may be required to stand in the very midst of the 'great deep' itself, where not even a sunken rock will afford a foundation on which to build; and then they must be either erected on open work of piles, or on a floating vessel strongly moored to the ground below, many of which invaluable though non-locomotive craft may be seen around our coasts, warning the mariner from the treacherous sandbanks that are so numerous in our tidal seas.

A novel class of towers has been designed and

erected by Mr. Alexander Gordon, consisting of iron plates bolted together. There are several fine examples of his light-towers at Jamaica, Bermuda, the Bahamas, and other places. They are well adapted for positions and countries where skilled labour and suitable materials are wanting.

Another description of light-tower, or lighthouse, deserving of notice, is that on the ingenious plan of Mr. Alexander Mitchell, supported on screw piles. Buildings of this class are especially applicable to shallow waters, at the estuaries of rivers, and similar situations, over flat soft ground of mud or sand. The Maplin, at the mouth of the Thames, begun in 1838, was the first of this description. It stands on nine piles, secured to as many iron screws, which are screwed down to a depth of 22 feet into the sand. These screws consist of a single turn of a flange, 4 feet in diameter, on the lower end of the iron pile. They were fixed in nine consecutive days, under the personal direction of the blind inventor. The piles are secured in place and bound together by suitable ties, and the dwelling-room and lantern are placed above the reach of the sea, which breaks harmlessly through the open work of iron piles, &c., beneath (see Plate 3). Similar buildings have been constructed at Fleetwood, Belfast, and other places.

Floating lights are never placed where a suitable position can be had for a fixed building—the reason being that their lights must be comparatively small; that they are liable to drag their anchors in violent storms, and thus, by their change of position, to mislead instead of guiding, although this does not often happen; that they are much more expensive, requiring eleven men to work them, whereas three men are all that are necessary to occupy a first-class light-tower—the cost of management of the former being about 1800*l.* per annum, and of the latter 350*l.*; also that they are much more troublesome, requiring to be periodically taken into dock to refit, on which occasions they have to be replaced by similar vessels. There are fifty-one floating lights on the coasts of the United Kingdom, being a greater number than appear in any other country, the United States of America having only thirty-nine. These craft are in general ordinary-shaped vessels, and are now expressly built for the purpose. The floating light-vessels of Mr. George Herbert's design are, however, circular, and are moored from their centre of gravity. They have immense stability and are comparatively motionless; they have been found to answer admirably where adopted for floating beacons, &c. Light-vessels are ordinarily painted of a dark red colour, to make them readily distinguishable from all other craft, and that colour, which is the opposite of green, being more conspicuous than any other on the surface of the water. The greatest depth of water in which any of these vessels at present ride is about 40 fathoms, which is the case with the one at the station of the Seven Stones, between the Scilly Islands and Cornwall. Light-vessels on the English shores are generally provided with gongs, which are kept sounding in foggy weather.

The lights on land, or lighthouses which are at the highest elevation, with the distances they command in clear weather, are given in the following table, compiled from the general return published by the Admiralty:—

	Year when erected.	Height of Lantern above high water.	Distances at which the lights are seen.
Lizard, ...	1751	224	20 miles.
Needles, ...	1786	469	27 "
Beachy Head, . .	1828	285	22 "
South Foreland, .	1793	372	25 "
Cromer, ...	1719	274	22 "
Flamborough Head,	1806	214	19 "
Inchkeith, . . .	1804	220	18 "
Isle of May, . .	1816	240	21 "
Dunnet Head, . .	1831	346	23 "
Sumburgh Head, .	1821	300	22 "
Cape Wrath, . .	1828	400	25 "
Barra Head, . . .	1833	680	32 "
Kintyre, ...	1787	297	22 "
Mull of Galloway,	1830	325	23 "
Calf of Man, . .	1818	375	22 "
St. Bee's Head, .	1718	333	23 "
Lundy Island, . .	1820	540	30 "
Cape Clear, . . .	1817	455	27 "
Clare Island, . .	1806	349	27 "
Skellig's Rock, .	1826	372	25 "

The lighthouse establishments of the United Kingdom were until recently conducted under entirely different systems, but gradually private rights in light dues have been extinguished, and the whole of the duties connected with the lighting and buoying the coast of England and Wales are now discharged by the authorities at the Trinity House, in London. In the article relating to that corporation full particulars will be found of the powers and privileges they at present possess. In Scotland they are under the management of the Commissioners for the Northern Lighthouses; and in Ireland, under the Port of Dublin Corporation. There is a second class of lighthouses, consisting of local or harbour lights, which are managed by corporations and local trustees, subject to the general control of the Trinity Board. The lighthouses are maintained by dues levied on all vessels which leave the harbours of the United Kingdom, at so much per ton per vessel, according to the number of lighthouses which the vessels pass.

There are in the United Kingdom about 420 lights of all kinds, the coast line being 9392 miles. Of these, England and Wales, with 2405 miles of coast, has 220; Scotland, with 4469 miles, 120; and Ireland, with 2518 miles, 80. The income and expenditure connected with them, and other matters under the control of the Trinity Board, in the year 1864, was as follows:—

INCOME.			
For Fees, &c., received under the	£	s.	d.
Merchant Shipping Act, . . .	54,366	17	9
For Light Dues received, viz:			
Per Trinity House			
Corporation, 206,775	4	8.

	£344,211	15	9

A principal object in the establishment of these buildings is to give intimation to vessels approaching the coast during the night as to the place in which they are. It is therefore of importance that the lights exhibited on the same line of coast should have some essential differences, so as to be readily distinguished by mariners. The different appearances thus required are given by having two lights placed either vertically or horizontally with respect to each other, or three lights, as at the Casket rocks, or by causing the lights to revolve or to appear only at certain intervals, and to remain in sight only for a given number of seconds at each appearance; or by the employment of lamps of different colours, as in some of the harbour-lights, which do not require to be seen at a great distance.

The mode of illumination adopted in the lighthouses of the ancients seems to have been either an open wood or coal fire, or the combustion of torches dipped in tar. No improvement was made in these systems for several hundred years, and so recently as the latter half of the last century the sea-lights of this country consisted of open coal fires. At that period however, this imperfect means of illumination was replaced by reflectors having lamps in their foci. These were gradually improved, in many variations of the catoptric or reflecting system, but the dioptric-holophotal plan, invented by Mr. Thomas Stevenson in 1849, is the one now almost universally adopted both in Europe and America (see Plate 2).

Attempts have several times been made to increase the power of the light itself, by the introduction of gas, and the Drummond and Magneto-electric Light, but as yet without much success, although sanguine hopes are entertained of the latter being some day made practically efficient. At present oil is the material employed, the variety known as colza being that universally used in the United Kingdom. The regulation standard of consumption in a first-class dioptric apparatus is 785 gallons per annum. In England the average consumption of all classes of

lights is below this standard, but in Scotland it is above it. In the former country and in Ireland the lamps of lighthouses are lighted from sunset to sunrise: in Scotland they are lighted at the commencement of the darkness and extinguished at dawn, according to a calculated table.

In 1825 the French government undertook the comprehensive scheme for thoroughly lighting their coast, and have since carried it into execution with the greatest possible care, introducing the most recent improvements throughout. They class the lights on their shore in four divisions, according to the power and range of visibility. The first class is visible at thirty miles; the second at twenty-five; the third at fifteen; and the fourth at six.

A few words of explanation respecting the accompanying plates seem desirable. Plate 1 is devoted to an illustration of the details of the Eddystone Lighthouse, showing, in fig. 2, a semi-elevation of the entire structure as seen from the south, and a semi-section of the same from east to west. The numerals vii., viii., ix., &c., refer to the different courses of masonry, whose mode of construction is explained in the accompanying diagrams (figs. 1, 3, 4, 5, 6, 7, and 8). In fig. 1, the italic letters, *a*, *b*, *c*, &c., show the different layers of masonry employed.

Plate 2 presents a view of a *Dioptric Revolving Lighthouse*, of which many examples now exist upon the British coast. By this means a more powerful illumination is obtained, and it is readily distinguished from a fixed light.

Plate 3 illustrates various new inventions in Light-house apparatus. Fig. 1 shows the section of the new *Facet Reflector*, and its action in throwing the diverging rays of the lamp into a beam of parallel rays; but much of the light by this mode is scattered and lost.

In fig. 2 we have a section of the *Holophotal Reflector*; *a a* being portions of a paraboloidal reflector which concentrates the divergent rays into a direct line of light, and *b b* a hemispherical reflector for sending forward all the light that radiates backward from the lamp. *L* is a glass lens for refracting into a parallel beam the central mass of the diverging light.

Fig. 3 is a section of Mr. Thomas Stevenson's *Dioptric Holophote*, invented in 1850. *LL* is a polyzonal lens; *pppp* are totally reflecting annular glass prisms; *a a a a* a hemispherical mirror composed entirely of prismatic rings of glass, so formed as to reflect totally the light that radiates in a backward direction from the lamp. See the action of the prism illustrated in fig. 4, where *fr r'* marks out the course of a ray of light thrown off from the prism *a b c*.

The *Central Burner* system of illustration, invented by Augustin Fresnel, is shown in figs. 5, 8, and 9. Fig. 8 is an elevation of the 'Beehive' apparatus; *ll* being lenticular rings acting by refraction, and *pp*, prisms acting by reflection. The effect of the combination is to concentrate nearly the whole sphere of light into a flat zone. On a similar principle is constructed Stevenson's *Revolving Apparatus* (fig. 1), where the light is received and collected into eight horizontal beams by lenses, &c.

Fig. 7 represents the model of a beacon for an *Apparent Light*. Here a rectangular lantern receives from the lighthouse on shore a beam of parallel

rays, *r*, which are totally reflected by the glass prisms, *P*, and concentrated by the lens and prisms, *B*, to a linear focus, whence they diverge as if from an actual lamp. Such an apparatus is fixed at Stornoway Bay, the beacon being erected on an exposed rock, 200 yards distant from the lighthouse. It was designed by Mr. Thomas Stevenson in 1855.

Plate 4, fig. 1, shows Peacock's *Refuge Buoy Beacon*, which of course is only employed in comparatively shallow water. It consists mainly of a semi-oval hull of plate-iron, *A*, with lopsides and a deck, surmounted by a cage-like framework of iron bars, *B*, inside of which is hung a bell rung by the rolling of the buoy. The frame carries on the top a three-sided pyramid, *D*, faced with looking-glass, to reflect the rays of the sun or moon. Inside the cage are seats capable of holding fifteen persons in the event of their taking refuge there from a wreck. The sign-plate, or label, *C*, gives the name of the locality where the buoy is moored.

In Plate 4, fig. 2, we supply a sectional elevation of the Fastnet-Rock Lighthouse, which stands on an isolated rock off Cape Clear, about 90 or 100 feet above the sea. It is built of cast iron.

	Ft.	In.
Total height, ...	93	9
Height of lantern, ...	30	0
Outside diameter at base, .	43	0
Do. of gallery, ...	19	10½

Fig. 3 represents the Maplin Sands Lighthouse, which stands on nine piles of wrought iron, 26 feet long, supporting a house, platform, and light-room.

LIGHT INFANTRY, a company of young active men, who are always selected from the rest of the regiment, and occupy the left of the battalion until called for separate service. The object of the light infantry movements, whether in battalion or in company, is to protect the advance and retreat of the troops, and to cover and assist the manœuvres or formation of larger bodies. There are several light infantry regiments in the British service distinguished for their gallantry in the field.

LIGHTNING. The general circumstances attendant on a thunder-storm are familiar to most persons. It will, however, be useful to state some of the most prominent, with a view to their explanation when regarded as electrical phenomena.

At first we see light clouds forming with jagged edges, the relative motions of which are frequently opposite and variable. The atmosphere at the surface of the earth enjoys a stillness and calm, accompanied with some elevation of temperature, as well as considerable barometric and hygrometric changes, which produce on the human system the sensations of closeness, faintness, and oppression, and appear even to the brute creation indicative of some awful and impending changes. Some of these light clouds appear stationary, as if the forces which produced contrary motions in the others made an equilibrium in them. A sound of distant thunder is heard, after which the lower region of the atmosphere is refreshed with light breezes. The calm returns, but the thunder-clouds approach nearer, and flashes of lightning are perceived at short intervals. The course of these is sometimes zigzag, when it is called forked lightning; the aberrations in its course show that it is near terrestrial objects, and is therefore justly

regarded as dangerous. In a few seconds after the discharge, heavy showers of rain or hail descend, and the atmosphere is again cooled. The blackness now becomes universal, and the thunder is heard in a loud and sudden clap almost at the same instant that the lightning is seen descending towards the earth with immense velocity, and resembling a globe of flame.

The colour of the lightning is a variable yellow, depending much on the density and composition of the strata of air through which the discharge takes place.

The identity of lightning with the discharge of an ordinary electrical machine is now well known. [ELECTRICITY, ATMOSPHERIC.] Both can dissolve metals, inflame combustibles, reverse the poles of a magnet, and destroy animal life. Professor Richman of St. Petersburg, having attached a species of electrometer to his apparatus for measuring the electric intensity of a thunder-cloud, immediately after a loud clap proceeded to read off the indication of his instrument, when a globe of electric fire was discharged through his body; he fell instantly quite dead, and decomposition ensued within forty-eight hours (in 1753).

When the electric discharge permeates generally the surrounding masses of weakly electrized vapour, the appearance then is that of a sudden and wide illumination, as in summer or sheet lightning. This lightning is harmless, and even beneficial, as indicating the restoration of atmospheric and electric equilibrium after it has been destroyed by the rapid succession of cold to heat.

A third kind of lightning is the globular, which appears like a luminous ball or globe of fire; it moves through the air at a comparatively slow rate, while forked and sheet lightning exist but for a moment. Lightning of this kind sometimes obtains the name of fire-balls: it rolls along the surface with a hissing noise, and often terminates in a disruptive discharge.

The changes of temperature, the electricity of the earth in contact with the air, and that produced by the chemical changes of the various matters of the globe, are the great causes of atmospheric electricity: thus earthquakes, volcanic eruptions, &c., are generally accompanied by violent thunder-storms. [THUNDER-ROD.]

LIGHTNING CONDUCTOR. [THUNDER-ROD.]

LIGHTS, ANCIENT. A light is a right to the enjoyment of free access of light to a man's premises or buildings, which right must not be impaired by the building or erection of any object in such way as to obstruct the light. By the 2 & 3 Will. IV. c. 71, s. 3, an absolute right to light may now be acquired by twenty years' uninterrupted enjoyment, unless the use has been enjoyed by some consent or agreement made or given by deed or writing.

The right to the free enjoyment of light belongs in the Roman law to the class of *Servitutes*, among which were the *Servitus altius non tollendi*, ne luminibus officiat, ne prospectui officiat ('Dig.' 8, tit. 2, s. 11, 12, 15-17).

LIGHTS, ARTIFICIAL. The modes of illuminating large buildings are explained in **BUILDING LIGHT**; **DRUMMOND LIGHT**; and **GAS**; while the articles **ARGAND LAMP** and **CANDLE** illustrate the common modes of domestic lighting.

We shall here confine ourselves more particularly to the various kinds of lamps in use in ancient and modern times. In all ages lamps have been articles of important consideration, especially among the Egyptians, Jews, Greeks, and Romans, and have been generally executed with much taste and magnificence. A lamp, in its simplest form, may be defined as a vessel of metal or earthenware, containing oil or fat, and supplied with a lighted wick; but its different forms and constructions have been as varied as the purposes to which it has been applied. Its first invention is assigned to the Egyptians, and Herodotus describes a feast of lamps held annually in Egypt. A similar custom is celebrated even at this time, with great magnificence, among the Chinese. Lamps were very extensively used by the Jews in all their religious ceremonies and public festivals. The lamp, or candlestick, with seven branches, placed in the sanctuary by Moses, and those lamps prepared for the temple by Solomon, were of crystal, fixed upon branches, and filled with oil. Among the Greeks and Romans lamps were sometimes burned in honour of the dead. In the early ages of Rome they were of a very simple construction, and made of terra-cotta or bronze; but in her more luxurious periods they were formed of Corinthian brass, silver, or gold, and arranged in stages, so as to produce a brilliant illumination. Among the discoveries of Roman remains no articles are more common than lamps, and they are found of all sizes and forms, and in every kind of material, of which a vast variety may be seen at the British Museum and in other antiquarian cabinets. Etruscan lamps are very rare; but those of Herculaneum and Pompeii, of a rich and elegant description, are abundant. In later ages we find the classical *bilychnis lucerna*, the *pharus*, and others, sometimes made of silver, and sometimes in the form of a crown or cross, with numerous branches.

In modern times the lamps have been as varied as the purposes for which they were intended. The old table and shop lamps of our forefathers emitted a brown and half-smoky light, owing to the absence of all scientific appliances. The Argand lamp, however, was a very ingenious contrivance, which, by means of a round and hollow wick, gave admission to a free current of air to the flame, and caused a clear combustion. [ARGAND LAMP.] A more extended knowledge of chemistry and mechanism has largely contributed to the improvement of modern lamps. Among others may be mentioned the *Soho* lamp, which is adapted for burning fat or tallow, instead of oil; the *Carcel* lamp, invented by a Frenchman, in which the oil is raised through tubes by clockwork, so as to overflow at the bottom of the wick, and thus keep it saturated; the *Meteor* lamp, which burns rape-oil; the *Solar* lamp, that consumes seal-oil, and in which three separate currents of air are brought to bear upon the flame; the *Camphine* lamp, of which there are various sorts, the fluid employed being camphine, which is distilled from common American turpentine; the *Benzole* lamp, the light of which is produced by a hydro-carbon called benzole; the *Bude* light, whose excellence depends on the mode of admitting air to an ordinary oil or gas flame. But the lamp now most in use amongst the more wealthy families is the *Moderator*,

which is very handsomely constructed, with ornamental pedestals, pillars, and glass globes. They are constructed on a very ingenious principle. The oil is contained in a reservoir within the pillar of the lamp, and is pumped upwards when required, while the wick, which is inclosed within a circular and hollow tube, is raised or lowered by a little knob or screw. Yet these lamps are found to be expensive in the long run, owing to their liability to get out of repair, and the expense of the oil, which should be pure colza, costing about 5s. per gallon; and the usual consumption being about half a gallon a week. The lamps in almost universal use amongst the humbler classes are such as are constructed to burn camphine, or rectified oil of turpentine, and the various kinds of naphtha, petroleum, and paraffine oils. They are exceedingly cheap and of remarkably simple construction; the chief requisite being to insure perfect combustion of the material. For this purpose the reservoir of fluid is placed much below the flame and the wick passes into it and sucks it up by capillary attraction. The glass chimney is made very narrow at the top and bottom, with an enlargement round the flame. By this shape such a great indraught of air is secured at the bottom, that in a well made lamp the smoke is imperceptible. These lamps give a brilliant light at a very little cost; but care should be exercised in the selection of the fluid to be burned, as some of the recently discovered rock oils are so inflammable and explosive that their use is dangerous.

In chemical experiments the Spirit-lamp has long been a valuable piece of apparatus.

Dr. Fyfe, in comparing gas, oil, and candles together, assumed an Argand gas-flame as a standard of intensity and price, and procured the following result in respect to the ratios of relative cheapness, the intensity of light being uniform:—

Argand gas-flame, ...	1·00
Naphtha, ...	2·00
Petroleum, ...	2·08
Paraffine, ...	2·21
Solar oil in Argand lamp, ...	3·98
Whale-oil, ...	5·00
Lard-oil, ...	5·08
Sperm-oil, ...	8·00
Tallow candle (two wicks), ...	12·70
Cocoa candle, ...	13·10
Tallow candle (one wick), ...	13·50
Composite, ...	14·50
Palm, ...	18·90
Wax, ...	25·90
Diaphane, ...	27·10
Margarine, ...	28·40
Spermaceti, ...	29·20
Composition, ...	29·20

According to this table, composition candles are nearly thirty times as costly as gas for an equal intensity of light.

Dr. Faraday has introduced an important arrangement for carrying off the products of combustion in gas and oil lamps. Air is admitted to feed the flame nearly in the usual way; but when the products of combustion have arrived at the top of the glass chimney, their progress is arrested by a covering of talc, and they are compelled to pass down between the chimney and another larger glass chimney concentric with it. The open space between the

two chimneys communicates with a pipe which is conducted in any convenient way into the open air; the carbonic acid, aqueous vapour, smoke, and other emanations from the flame, have no means of escape except through this tube, and they are thus wholly cut off from contact with the air of the room. The mode of carrying out the arrangement may be varied in its details; but the general result is said to be that the light is brighter, the space around the lamp cooler, and the air of the room less vitiated, than when common open burners are used. Many other ingenious arrangements have been adopted by different inventors, either to lessen the production of smoke, or to carry off the products of combustion without allowing them to mix with the air of the room.

LIGHTS, NORTHERN. [AURORA BOREALIS.]

LIGNIN, or vegetable fibre, is the substance which remains after a plant has had its soluble matter dissolved out of it. Lignin, properly speaking, constitutes the skeleton of the trunk and branches of the tree. It varies in different kinds, as to its colour, hardness, texture, and specific gravity. The texture of lignin is always porous; these pores, when fresh, contain the juices of different substances; during the drying of lignin the water evaporates, and leaves the matters dry which it held dissolved. When dry, lignin is a non-conductor of electricity. When exhausted of air in its pores, it is much heavier than water. When kept entirely dry, or entirely immersed in water, it resists decay for centuries; but when alternately wet and dry, it gradually decomposes. The wood inclosing Egyptian mummies is found in good preservation, although some of it must be about 3000 years old.

Concentrated sulphuric acid in the cold converts lignin into gum; and if the mass thus obtained be boiled with water, it is changed into grape-sugar. When wood (or lignin) is heated in iron cylinders, a great variety of important substances are obtained, besides charcoal—such as pyroligneous acid, pyroxilic spirit, creasote, and tarry matter.

LIGNITE. Fossil wood carbonized to a certain degree, but retaining distinctly its woody texture, is thus designated: a greater degree of change constitutes cannel and common coal, in which the original structure of the constituent plants can only with difficulty be traced; a less change belongs to peat, so that lignite occupies a place between coal and peat. Jet, Surturbrand, moor coal, Bovey coal, Cologne earth, and basaltic coal are considered to be varieties of lignite. Lignite often occurs in beds of considerable thickness and extent, and supplies to particular districts a bad substitute for coal. In general, lignite is most plentiful in the tertiary strata, and coal among the older rocks of the secondary series. Lignite is found in various parts of England, France, Italy, and Switzerland.

LIGNUM-VITÆ or GUAIACUM WOOD, the wood of a genus of trees of the natural order *Zygophyllaceæ*, natives of the tropical parts of America, but chiefly obtained from Jamaica and St Domingo. This wood is remarkable for its hardness, heaviness, and exceeding toughness. The heart-wood, which is the part used, is of a dark, greenish-brown colour, rarely more than 8 inches in diameter. The tree itself grows 30 or 40 feet high, and has generally a crooked stem and knotty branches. Lignum-vitæ is

much valued, and used for many purposes, chiefly by turners, and for making ships' blocks, rulers, pestles, bowls, and wheels for pulleys. Shavings, raspings, the bark, and a resin obtained from the stem, are used in medicine.

In the year 1864 there were 2074 tons of lignum-vitæ, valued at 14,729*l*, imported into the United Kingdom.

LIGNY. [MEUSE.]

LIGULATE, in botany, a term used to describe the form of the *corolla*, or flower leaves, in many plants which belong to the natural order *Compositæ*, and other orders. When the corolla of one petal splits and spreads out in the form of a tongue, the flower is said to be ligulate.

LIGUORI, ALPHONSO, MARIA DE, a celebrated writer on casuistry, and founder of the religious order of Liguorians or Redemptorists, was born at Marianella, near Naples, in 1696. He practised as a lawyer with success till 1722, when he suddenly relinquished the profession, and assumed the monastic habit. Ordained a priest in 1726, he preached every day to the common people with so much zeal and emotion, that he was called the apostle of the poor and ignorant. In 1732 he founded the order of the Holy Redeemer at Villa Scala, which was approved by the pope in 1749, and exists to this day in various parts of the world. Contrary to his own wish, Liguori was made a bishop in 1762, an office which the infirmities of age compelled him to resign in 1775, when he retired to Nocera de Pagani, the principal house of the order he had founded, where he died in 1787, and was solemnly canonized in the Roman Catholic Church in 1816.

The works of Liguori fill seventy volumes 8vo, and embrace almost every department of theological learning. They have been translated entire into French and German, and in great part into other European languages. He was one of the principal advocates of the doctrine of probability, so strongly condemned in Pascal's sixth letter.

LIGURIA (called by the Greeks *Ligyctia* and the inhabitants *Ligyes*, and *Ligustini*), a division of ancient Italy, on the west, corresponding nearly with Genoa and Nice. It was separated in the time of Augustus from Etruria by the river Macra (*Magra*), and was bounded on the north-east by Gallia Cisalpina, and on the west by the province of Gallia. The most important places in Liguria were Albium Intemelium (*Vintimiglia*), a place of some importance, and a municipium, the capital of the Intemelii; Albium Ingaunum (*Albenga*), the capital of the Ingauni; Genua or Genoa; Dertona (*Tortona*), in the interior, a Roman colony, surnamed Julia; Alba Pompeia (*Alba*); Asta (*Asti*); and Pollentia (*Polenza*).

The Ligures in more ancient times extended as far as the Rhône in France; and they also appear to have inhabited part of Spain and Corsica. The Ligurians of Italy were finally subdued by the Romans B.C. 166.

LIGURITE, a crystalline mineral, of which the primary form is an oblique rhombic prism. Colour, yellowish green or apple-green, and translucent. As a gem it is superior to chrysolite in colour, transparency, and hardness.

LIGUSTRUM, a genus of plants belonging to the natural order *Jasminaceæ*.

L. vulgare, Common Privet, is a bushy sub-evergreen shrub, growing in hedges and thickets in Great Britain, and a native of the south-west of England. In point of utility and ornament few shrubs exceed the privet. Its chief use is to form hedges either for shelter or ornament. It bears cutting well, and is not liable to be disfigured by insects. Having fibrous roots, it robs the ground less than almost any other shrub. It is one of the few plants that will grow in the smoke of London; it also thrives under the dripping of other trees. The wood is hard and fit for timber. From the pulp of the berries a rose-coloured pigment may be prepared; with the addition of alum, they dye wool and silk of a good durable green.

LILAC. [SYRINGA.]

LILIA'CEÆ, an important natural order of Endogens, containing many of the most beautiful plants of that class of the vegetable kingdom. A large proportion, especially of those of cold countries, consists of bulbous plants, producing annually a stem which perishes after having produced its leaves and flowers; others have an annual duration with perennial fleshy roots; and a few acquire, in warm countries, a stem of very considerable size, as the dragon-tree, *Dracena draco*, of which there is an ancient specimen in Teneriffe, with a stem many feet in diameter. The principal garden flowers of this order are tulips, lilies, fritillaries, day-lilies, tuberoses, and dog-tooth roses. *Hyacinthus Orientalis* is the common hyacinth, of which the Dutch florists at one time had more than 2000 varieties.

The greater part of this family are of no known use: we find, however, among them aloes, yielding the valuable purgative medicine of that name; squills (*Squilla maritima*), whose bulbs secrete a viscid substance much employed as an emetic, diuretic, and expectorant; and several plants which yield a tough and valuable fibre, such as *Phormium tenax*, or New Zealand hemp, *Sansevieria zeylanica*, or bowstring or African hemp, *Yucca filamentosa*, &c. What are called alliaceous plants, such as the onion, garlic, &c., are species of this order, of which between eighty and ninety genera are known. Lindley enumerates 155 genera in this order, including 1250 species.

LILIUM, a genus of plants, the type of the natural order *Liliaceæ*. *L. candidum*, common White Lily, blossoms early in the summer, and has been cultivated in our gardens from time immemorial. The roots are the only parts of the plant available in medicine, and they are frequently employed as emollient poultices, owing to the mucilaginous matter which they contain. It is, however, doubtful whether they are more efficacious than poultices formed of bread or farina. This species, as well as others, is cultivated in Siberia, and eaten like the potato. The scent of the lily is exceedingly powerful, and peculiarly distressing in some cases. Murray mentions an instance of death ensuing from exposure to the odour of this plant. *L. martagon*, Turk's Cap Lily, though not a native of Great Britain, is naturalized in copses in many places.

All the species and varieties of *Lilium* are valuable as plants of ornament for the beauty of their flowers, which have a noble appearance. They are proper for the pleasure-ground, and if planted with judg-

ment, succeed each other in blooming upwards of three months. The common White Lily, the Orange

Syrian Lily.

Lily, and Martagon will thrive under trees. The Syrian Lily has recently been cultivated with success. The orange lily also answers well for small gardens and confined situations in towns and cities.

LILLE, the capital formerly of French Flanders, now of the department of Nord, is situated in 50° 38' 44" N. lat., 3° 3' 37" E. long., at a distance by railway of 155 miles N.N.E. of Paris, 67 miles S.W. from Calais, and had, in 1861, a population of 131,827. It stands in a fertile and level country, at the junction of the Haute-Deule and the Basse-Deule, as the two cuts of the canal that unites the Scarpe and the Lys are called. These two cuts are united by a third, called Moyenne-Deule, which passing west of the town conveys barges too heavily laden, or too large, to pass through any of the numerous channels that traverse the city for purposes of commerce, or to drive the machinery of the numerous factories. The town is well-built; the streets are regular, wide, and provided with foot-pavements; the houses are in general three or four stories high, and built of brick or limestone. It contains thirty-four squares and market-places, thirty bridges of all sizes, about 200 wide streets, and many factories and mills, which, together with a far greater number in the environs, announce to the traveller by their lofty chimneys that he is approaching one of the great hives of industrial activity. Lille, which is entered by seven gates, is surrounded by very strong fortifications and wet ditches, and defended by a citadel, said to be the masterpiece of Vauban. Its shape is nearly oval, its length within the walls being 2560 yards, and its breadth 1278 yards. The citadel is a regular pentagon of 426 yards' diameter; it is situated south-west of the town, and separated from it by a wide esplanade, which, crossed by the Moyenne-Deule, and planted next the town with

several avenues of trees, forms a fine promenade, close to which is the handsome Pont Royal. There are also barracks and magazines on the north-western side of the town.

The most remarkable public structures of Lille are the churches of La Madeleine, St. Maurice, and St. Paul; the town-hall, which, built by John the Bold in 1430, was for a long time the palace of the dukes of Burgundy; the Mont-de-Piété, founded in 1610; the Paris gate, which is a triumphal arch in honour of Louis XIV.; hospitals; the large corn-stores at the end of the Rue Royale; the theatre, the concert-room, one of the finest in France; the museum, established in a fine old abbey, and containing the public library of above 20,000 volumes, a gallery of valuable paintings, and the archives of the town; and the Napoleon bridge across the Moyenne-Deule, which unites the part of the esplanade that serves for a promenade to the part next the citadel where the troops are drilled. There are also a bourse; medical school, formerly the palace of Richebourg, with a famous collection of drawings by Raffaele and others, now comprising the chief municipal offices; Hotel de Ville; several other Roman Catholic and Protestant churches, Jew's synagogue, prefecture, exchange, prisons, mint, &c., an academy of music and architecture, and a botanic garden.

The manufactures of Lille are very important; they consist of all kinds of cotton goods; linen and linen thread, lace, tulle, blankets and other woollen stuffs; velvets, paper, leather; steam machinery and ironmongery; gin, beer, glass, soap, tape, hats, carpets, chemical products, mineral acids, &c. There are also government establishments for the manufacture of tobacco and gunpowder, and an extensive gold coinage. The vicinity is studded with bleaching grounds, rape-seed oil mills, and beet-root plantations, the last-named being very extensive. Railways and canals connect the town with all parts of France and Belgium.

Lille is the seat of tribunals of first instance and of commerce, and the head-quarters of the Third Military Division; it has a bank, a council of prud'hommes, a college, a school of painting, various establishments for the gratuitous instruction of working manufacturers, and a great number of charitable institutions. Lille belonged to the counts of Flanders, kings of France, and earls of Burgundy, and was finally annexed to the crown of France by Louis XIV., in 1667. It was taken by siege by the allies, under the duke of Marlborough, in 1708, and unsuccessfully bombarded by the Austrians in 1792.

LILLEBONNE. [SEINE-INFÉRIEURE.]

LILLY, WILLIAM, was born May 1, 1602, at Diseworth, in Leicestershire. He removed to London in 1620, where he became servant to a mantua-maker. This situation he exchanged in 1624 for one of a less menial character. In 1627 his master died, whereupon Lilly married the widow, with whom he received the sum of 1000*l.*, and on her death within a few years immediately took another wife, and thus augmented his fortune by 500*l.* In 1632 he began the study of astrology under one Evans, a clergyman who had been expelled from his curacy for practising numerous frauds under pretence of discovering stolen goods. The fame which Lilly soon acquired for casting nativities and foretelling events was such that

he was applied to, in 1634, to ascertain, 'by the use of the Mosaical or Miners' Rods,' whether there was not extensive treasure buried beneath the cloisters of Westminster Abbey. Permission having been obtained from the dean, on condition that he should have his share of whatever might be found, 'Lilly and thirty other gentlemen entered the cloisters one night, and applied the hazel rods;' but after they had disinterred a few leaden coffins, a violent storm arose, which so alarmed them that they all took to flight, and ran home. In 1644 he published his first almanac, by the title of 'Merlinus Anglicus, Junior;' and such was the avidity with which the people received his prognostications, that the whole edition was sold in a few days.

During the contest between Charles I. and the Parliament, Lilly was consulted by the Royalists, with the king's privy, as to whether the king should sign the propositions of the Parliament, and he received 20*l.* for his opinion. At the same time he was employed by the opposite party to furnish them with 'perfect knowledge of the chiefest concerns of France,' for which he received 50*l.* in cash, and an annuity of 100*l.* per annum. The latter he enjoyed only two years. Until the affairs of Charles declined, he was a royalist; but after the year 1645 he engaged heartily in the cause of the Parliament, and was one of the close committee to consult upon the king's execution. He died of palsy, June 9, 1681, and was buried at Walton-upon-Thames. The character of Lilly has been faithfully drawn by Butler under the name of Sidrophel, although some authors have supposed that character to have been intended for Sir Paul Neal. After the Restoration he made several applications to the ministry to be employed as a prophet, in which capacity he had been liberally patronized by the previous government, but in every instance he had the mortification of being refused.

LILY, or LILLY, WILLIAM, was born at Odiham in Hampshire, about 1468, and at eighteen years of age was admitted a demy of Magdalen College, Oxford. Having taken the degree of B.A., he quitted the university and travelled in the East. He certainly remained five years at Rhodes, and thence he went to Rome, and studied. On his return to England in 1509, he set up a private grammar-school in London, and became the first teacher of Greek in the metropolis. In 1512, Dean Colet, who had just founded St. Paul's school, appointed him the first master. He followed this useful and laborious employment for twelve years. Lily died of the plague in February, 1523, and was buried in the north churchyard of St. Paul's. His principal literary production was the 'Brevissima Institutio, seu Ratio Grammaticæ Cognoscendæ,' 4to, London, 1513. The English rudiments were written by Colet, and the preface to the first edition by Cardinal Wolsey. The Latin Syntax was chiefly the work of Erasmus. Lily numbered Erasmus and Sir Thomas More among his intimate friends.

LIMA, the capital of the republic of Peru in South America, is situated in 12° 2' 34" S. lat., and 76° 58' W. long., about 6 miles from its port, Callao, which is on the shores of the Pacific, and with which it is connected by a railway. [CALLAO.] Lima is built in a spacious and fertile valley, traversed by a small river called the Rimac. The river washes the northern

walls of Lima, and over it there is a handsome stone bridge leading to the suburbs of St. Lazaro, and to the Alameda, or public walk. Elsewhere the city is inclosed by a bastioned wall, entered by six gates. It is about two miles in length, and one and a quarter in its greatest breadth. The houses are low and have rarely more than one floor: they are lightly built, on account of the frequent earthquakes, which have repeatedly reduced the city to ruins. The streets are regular and wide, but the pavement is bad. The city occupies a nearly triangular space, the base extending along the banks of the river. A fine street leads from the bridge to the Plaza Mayor, or great square, in the midst of which is a large fountain. On the north side of the square is the government palace, a large but gloomy-looking edifice; on the east side are the cathedral and the archiepiscopal palace, now partly occupied by the Peruvian senate—the former is a handsome building of considerable extent; on the west side is the town-hall and the city prison; the south side is occupied by private houses. The other principal edifices are the parish church; the former residence of the viceroy (now the court-house); numerous churches, a convent, the founding asylum, eleven public hospitals, a university, partly appropriated to the meetings of the North Peruvian chamber of representatives; a national and a public museum, a public library with rare books; ecclesiastical, Lancastrian, naval, and other schools; a theatre, a bull-ring, a cock-pit; and outside of the walls are a public cemetery and baths.

Lima is of Spanish origin, and is the most handsome city in South America, its numerous domes and spires giving it a magnificent appearance. Its vicinity is fertile, and large quantities of provisions and live stock are produced. The climate is pleasant and reputed to be healthy, the elevation being 453 feet above the sea; but the mortality is high, partly owing perhaps to great neglect of drainage and disposal of refuse. There are abundant dews, but no rain. The mean temperature of the year is 73·3°; in winter, 68·1°, and in summer, 77·6° Fahr.

This city was for a long period the grand commercial depot for all the western coast of South America, and it still has a large trade, its exports consisting of silver, copper ore, bark, soap, vicuña wool, chinchilla skins, nitre, sugar, &c.; and the imports of manufactured goods, wines, silks, and brandy.

The population is estimated at about 70,000, consisting of free mulattoes, slaves, Indians and mestizos, and a few Europeans. The manufactures are neither numerous nor extensive. The principal manufactured articles are utensils and vessels of silver, gilded leather, cotton cloth, gold lace, and epanettes. A glass factory has also been established. Among the creole inhabitants are many rich families, who owe their fortunes to the mines, and are now large landed proprietors.

LIMACINEA, M. de Blainville's name for his third family of *Pulmobranchiata*, the first order of his second sub-class, *Paracephalophora monica*. M. de Blainville adds, as an observation, that all the animals of this family are terrestrial, and that all feed on vegetable substances. *Testacella*, however, feeds chiefly on earth worms. [HELICIDÆ, LIMAX.]

LIMAX, the Latin name for those air-breathing,

naked, gastropodous molluscs so injurious in the garden, and known vernacularly by the name of *Slugs*. Cuvier says, the slugs (*les Limaces*) have an elongated body, and for a mantle a fleshy compact disc, which occupies the anterior part of the body alone, and covers the pulmonary cavity only. This disc contains, he adds, in many species a small oblong and flat shell, or at least a calcareous secretion in lieu of it. The orifice of respiration is on the right side, towards the front, and the anus is pierced at its posterior border. The four tentacles are put forth and withdrawn by unrolling themselves like the fingers of gloves, and the head itself can be withdrawn in part under the disc of the mantle. The organs of generation open under the right upper tentacle. There is but one jaw (upper), in the form of a dentilated crescent, which serves them to gnaw with much voracity the herbs and fruits to which they do so much damage. Their stomach is elongated, simple, and membranous.

Cuvier then notices the following genera—*Arion*; example, the Red Slug: *Limax*; example, the great Gray Slug, often found in damp cellars; the small Gray Slug, and others: *Vaginulus*, *Testacella*, and *Parmacella*.

The slugs of our fields and gardens often commit devastations of serious consequence. Gardeners are constantly racking their invention to free themselves from their devouring hosts. Quicklime, soot, fine coal ashes, and saw-dust, have been used as defences for young and tender plants. The virtue of the first is soon exhausted, and the slugs after a while do not care much for the second; but if the soot be plentifully and frequently renewed, it will keep them away in great measure. Coal-ashes, not too coarse, and saw-dust, annoy them by sticking to their feet and impeding them. A stout, coarse horsehair line, such as is used for hanging clothes out to dry, coiled round the stems of wall fruit-trees and stretched along the wall, will operate as a protection to the fruit from both snails and slugs, in consequence of the bristly surface presented to them, and which they shrink from encountering. Care must of course be taken that they do not get under it. Watering evening and morning with strong fresh lime-water is said to have a good effect, for it penetrates about the roots of the plants and into the earth, where they lie hid. Thin slices of any vegetable of which they are more fond than of the crop to be protected will allure them, and they may be thus killed by scores early in the morning by dividing them suddenly with a sharp instrument. The dead bodies should be left on the spot as a bait, for we have seen the living slugs preying upon the exposed bowels of the dead ones, most probably attracted by the half-digested vegetable matter. Ducks destroy great numbers of these pests, and thus fatten themselves, but they are apt to trample down a young and delicate crop of vegetables.

LIMB. (Astronomy.) The edge of a planet is called its limb; also the edge of any circle which forms part of an astronomical instrument.

LIMBER, in artillery, a two-wheeled carriage for carrying the ammunition in field practice. It forms one-half of the field-equipage, the mounted cannon forming the other. To *unlimber* is to unhook from the gun the part of the equipage which has the ammunition box, and thus to leave it free to be *served*.

To *limber up*, on the other hand, is to join both together again.

LIMBURG, a province of Belgium, lying between 50° 44' and 51° 18' N. lat., 5° 2' and 5° 52' E. long., is bounded N. by North Brabant, E. by the duchy of Limburg, from which it is separated by the Maas, S. by Liège, and W. by Antwerp and South Brabant. The area is 934 square miles, and the population in 1861 was 196,816. The surface is flat, except in the south, where there are a few hills. The east of the province, along the left bank of the Maas, is fertile in corn, hemp, flax, tobacco, madder, fruits, &c. The district also between the Jaar and the Demer possesses a fertile soil. The rest of the province consists of a sandy soil, presenting towards the north extensive barren heaths, and many marshes. The pasture-lands are extensive, and cattle-feeding is more attended to than tillage; there is a good breed of horses, and bees are carefully tended. The principal rivers are the Maas, which receives the Jaar on its left bank at Maastricht; the Demer, which, rising W. of Maastricht, runs westward past Hasselt, and having received several small feeders from both banks, enters South Brabant on its way to join the Dyle, a feeder of the Scheldt; and the Dommel, which rises in the north of this province, and flows through North Brabant, where it enters the Maas at Crèveceur. Iron, calamine, coal, and turf, are the chief products of the province.

Hasselt, the capital, is a well-built town of 9895 inhabitants, on the Demer. It has some manufactures of linen, leather, tobacco, beer, spirits, point lace, salt, &c. A branch railroad leads from Hasselt through St. Trond to the Liège-Malines line, which it joins at Landen.

St. Trond, 10 miles from Hasselt, stands on the Messelbeck, a feeder of the Demer, and has 9400 inhabitants. It is joined by a branch railroad to the Liège-Malines line. The chief manufactures are soap, tobacco, and lace; and there are also breweries and distilleries.

Bilsen, a small place of 3085 inhabitants, on the left bank of the Demer, has iron mineral springs and potteries, with manufactures of cutlery and earthenware. *Tongres* or *Tongern*, on the Jaar, is a well-built town with 6180 inhabitants, who manufacture chicory, leather, and hats. It has besides a trade in corn, and some breweries. It was ruined by Attila in his retreat from Chalons. In a valley near the town there is an iron mineral spring, which has been described by Pliny. *Maaseyk* or *Mazeik*, a town of 4000 inhabitants, stands in the north-east of the province, on the left bank of the Maas, and has manufactures of leather, paper, hats, tobacco, pottery, beer, spirits, and ropes. This was the birthplace of the brothers Van Eyck, inventors of painting in oil.

LIMBURG, a Dutch province with the title of duchy, extending between 50° 45' and 51° 47' N. lat., 5° 35' and 6° 13' E. long., is bounded on the east by Rhenish Prussia, on the other sides by the provinces of North Brabant, Liège, and Belgian Limburg. The area is 855 square miles, and the population in 1862 was 218,775. It extends 71 miles from N. to S., with an average breadth of 14 miles, but at some points the width does not exceed 3 miles. In the southern part, extending along the right bank of the Maas, the soil is fertile, but in the

north bogs, moors, and marshes cover a great part of the surface. Cattle-breeding and agriculture are the chief occupations of the inhabitants; the products are similar to those of the Belgian province of LIMBURG. The principal rivers besides the Maas are its feeders from the left, the Roer and the Neisse.

Maastricht (*Trajectum ad Mosam*), the capital of the province, stands on the left bank of the Maas, at the head of a branch railway from Cologne, 110 miles S.E. of Amsterdam. The inhabitants numbered 28,080 in 1862. The part of the town that stands on the right bank of the Maas is properly a suburb, and called *Wyck*. The town is regularly and well-built, and contains several spacious squares, one of which, the parade, is inclosed by an avenue of trees. The town-hall, in the great market-place, and the church of St Gervais, are the most remarkable buildings. There are several Roman Catholic and Calvinist churches, two hospitals, two orphan asylums, and a lyceum. The manufactures consist of woollen cloth, flannel, cotton, paper, leather, fire-arms, soap, beer, and spirits. The town is very strongly fortified; the citadel is erected on a hill called Petersberg, on the west bank of the Maas. Underneath this hill is a stone quarry of great extent, abounding in many curious and interesting petrifications; it is said to be intersected by above 20,000 passages, forming a most intricate labyrinth. Maastricht was taken by the French in 1648, 1673, 1748, and 1794. From 1795 till 1814 it was the capital of the French department of Maas-Inférieure.

The other towns are *Sittard*, 13 miles N. by E. from Maastricht; population, 4200; *Roermonde*, or *Euremonde*, a fortified place at the entrance of the Roer into the Maas, with 9246 inhabitants, who manufacture woollen cloth, leather, beer, soap, and vinegar. It has also a considerable general and transit trade. The fortifications were dismantled under Joseph II., but it is still the residence of a military commandant. *Vaels*, a frontier town, a little W. of Aix-la-Chapelle, with 3300 inhabitants; *Venloo*, a fortified town on the right bank of the Maas, and near the Prussian frontier, which has 7000 inhabitants, several breweries, distilleries, tile works, tobacco-factories, vinegar works, tin and lead foundries, tan yards, and spinning mills; the fort St. Michael, which forms part of the defences, stands on the left bank of the Maas, and is joined to the rest of the town by a bridge; and *Weerd*, which is situated in a marshy district, near the borders of North Brabant, on the Bree, and has 6690 inhabitants, who manufacture hats, cloth, tobacco, chocolate, candles, leather, and stockings.

LIMBURG. [LIÈGE.]

LIME. [CALCIUM; MANURE.]

LIME, MEDICINAL PROPERTIES OF. Though lime exists in almost all plants, yet it is more particularly the characteristic element of animal structures, into which it is introduced with the food, as well as often by the water drunk, especially when hard. A deficiency of lime in the body causes a softness of the bones to result; while an excess of it occasions preternatural induration of the bones, morbid growths from them, or exostoses, ossifications of the cartilages, of the heart and arteries, as well as depositions of calcareous concretions in various glands and cavities, such as the urinary bladder. [CALCULUS.] The

action of lime on the human system varies considerably, according to the state in which it is when introduced into or applied to it. Thus quick-lime is violently escharotic, causing inflammation, and often decomposition, of the part which it touches, and is never employed save when the actual destruction of the part is intended. In a state of great dilution, such as that of lime-water, or when rendered mild by combination with carbonic acid or phosphoric acid, it scarcely produces any immediate or direct action beyond what results from its combining with the acids of the stomach, and if in considerable quantity absorbing the mucous and other secretions. It likewise checks the secretions of mucous membranes with which it is not brought into contact, such as those of the bronchia. After its absorption into the system, it augments the secretion of the kidneys, and at the same time hinders the excessive formation of uric acid.

LIME-TREE. [TILIA.]

LIMERICK, an inland county of the province of Munster, in Ireland, bounded N. by the estuary of the Shannon, W. by Kerry, S. by Cork, and E. by Tipperary. It lies between $52^{\circ} 17'$ and $52^{\circ} 47'$ N. lat., and between $8^{\circ} 5'$, and $9^{\circ} 22'$ W. long. The greatest length E. to W. is 54 miles; the greatest breadth N. to S. is 35 miles. The area is 1061 square miles, or 680,842 acres, of which 526,876 are arable, 121,101 uncultivated, 11,575 in plantations, 2759 in towns, and 18,531 under water. The population in 1861 was 217,277, of whom 205,728 were Roman Catholics, and 9886 belonged to the Established Church. The inhabitants in 1851 numbered 262,136.

The general surface of Limerick is an undulating plain, sloping towards the Shannon on the north, and surrounded on its southern and western borders by a margin of mountain groups and hilly uplands. A mountainous tract occurs also in the north-eastern extremity of the county. The north-east mountains are the Slieve Phelim, and the Bilboa groups. The country between the western declivities of the Slieve Phelim hills and the Shannon is mostly flat and boggy. The principal rivers of the county are the Shannon, the Maigue, Deel, and Mulcair.

Although the Shannon does not lose the character of a river until after passing beyond the bounds of this county, yet for all the purposes of commerce it is equivalent to an equal length of sea-coast from Glin to Limerick, a distance, including the windings of the river, of about 35 miles.

The level part of the county consists of carboniferous limestone. The mountain groups and detached eminences of its eastern and southern margins are formed by the protrusion of older rocks; and the high lands on the west consist of more recent series superimposed. The Slieve Phelim and Bilboa groups, in common with the extensive range of which they form a part, consist of a nucleus of clay-slate supporting flanks of yellow sandstone and conglomerate disposed in conformable beds. Small portions of old red sandstone, crystalline green, flinty limestone, and other rocks, appear at various parts of the surface. Pallas Hill is distinguished by the presence of columnar basalt, which overlies the amorphous trap of its northern brow. The mountainous district on the west of the county belongs to the great Munster

coal tract, which is probably the most extensive in the British islands; but the coal is slaty, and the mines difficult to work on account of the great inclination of the beds. Fine dark-coloured marble, and small quantities of iron, copper, and lead are met with in the county.

A tract of extraordinary fertility, called the 'Golden Vale,' occupies the greater part of the centre of the county. The soil is a rich, mellow, crumbling loam, and is equally suited to grazing or tillage: it is chiefly in pasture. A still richer soil is that of the 'Corcasses,' which extend for fifteen miles along the southern bank of the Shannon, from a little below Limerick to the embouchure of the Deel. They yield the greatest wheat-crops raised in Ireland; and their produce of potatoes is also large. The soil of the remainder of the limestone plain is very good for tillage, and yields an excellent pasture for dairy cattle and sheep. Pasture and dairy farming are the staple occupations of the people. Tillage was formerly little attended to, but is now increasing, and much bog and mountain land has been reclaimed. Horned cattle, sheep, and pigs of a very superior description, are bred in large numbers by the dairy farmers. Great quantities of butter are made and exported. The trade in corn, cider, and other articles of produce, is also very extensive.

The climate of the county is mild, but humid.

There is a small manufacture of coarse woollens for home consumption, and the bleaching of linen is carried on, but on a contracted scale. There are paper-mills, and large and powerful mills for the grinding of corn.

Divisions and Towns.—Limerick is divided into 13 baronies and 131 parishes, and is in the dioceses of Limerick and Emly, with small portions in Cashel and Killaloe. It is in the Cork or south-western military district; in the Munster circuit, and the assizes are held in the city of Limerick. The county returns two members to Parliament. The number of electors in 1865 was 6318.

The following are the principal towns, with the population of each in 1861:—

Askeaton, 18 miles W.S.W. from Limerick, is situated on the river Deel, about two miles above its confluence with the Shannon. The Deel is navigable for vessels of 60 tons up to the town, which contains a church and Roman Catholic chapel. Population, 1637, including 1532 Roman Catholics.

Kilmallock, 20 miles S. by E. from Limerick, is situated on the small river Labach. It is a very ancient town, and was formerly very important on account of its strength and a monastery founded there in the sixth century. It was the chief town of the Desmond branch of the Geraldines, was surrounded by a wall, of which considerable portions remain, and was fortified; but the fortifications were destroyed by Cromwell, and again in 1690 by the duke of Berwick, after they had been partly restored. The town consists chiefly of a street of stone houses frequently three stories high, with mullioned windows and arched doorways of cut stone. The ruins of this place, both civil and ecclesiastical, are very interesting. Population, 1393.

Limerick. [LIMERICK.]

Newcastle, a market town, 25 miles S.W. from Limerick, is situated on the Arra, a beautiful stream,

which flows through the town in its progress to the Deel. Coarse cloths are manufactured in the town, which contains a neat modern church, a Roman Catholic chapel, infantry barracks, a union workhouse, and a market-house. Population, 2452, of whom 2354 were Roman Catholics.

Rathkeale, a market town and municipal borough, 17 miles S.W. from Limerick, is situated on the west bank of the Deel, and is the largest town between Limerick and Killarney. It contains many good houses and shops, and has a good retail trade. From the various ruined castles in the immediate vicinity, and the remains of a priory in the town, it appears to have been a place of considerable antiquity. It contains a court-house, union workhouse, and seven places of worship. Population, 2751, of whom all but 164 are Roman Catholics. The population of the entire parish is 5152, including many descendants of German Protestants, termed 'Palatines,' established here by the Southwell family, whose seat, Castle Matress, is immediately south of the town.

History and Antiquities.—Prior to the arrival of the English, Limerick constituted part of the petty kingdom of Thomond, or North Munster. Donald O'Brien was prince of this territory at the time of the English invasion; and in order to carry out a feud with a rival chieftain, he was among the first to tender his homage and receive an English garrison into his city, in 1172. But he did not long continue loyal, and after many conflicts a considerable portion of Limerick was given by King John to the Fitzwalters, the Fitzgeralds, and other great families. These new settlers brought in a colony of English, chiefly from Bristol and Chester, who took up their residence in the city and towns near the river. The greater portion of the county was possessed by the powerful family of the Fitzgeralds, earls of Desmond, until their final forfeiture by Gerald, the sixteenth earl, in 1586. The estates of this unfortunate nobleman in Limerick alone consisted of 96,165 acres, which were divided among twelve individuals, most of whose names are now extinct in the county. The war which ensued throughout Munster was an obstinate and disastrous one. On the breaking out of the rebellion in 1641, the city of Limerick and all the chief castles of the county, with one or two exceptions, fell an easy prey to the insurgents, in whose hands they for the most part continued until the capture of Limerick by the parliamentary forces under Ireton, in 1651. The forfeitures which ensued embraced almost the entire county, and introduced a numerous new proprietary. The war of the Revolution terminated in further forfeitures. From this time until the latter end of the last century the county continued undisturbed; but many outbreaks occurred in the earlier part of the present century.

Limerick is among the richest of the Irish counties in antiquities. There are extensive Cyclopean remains on the hill of Knockfennel, near Loch Gur. The fort on the western pinnacle of the hill is a circle of 360 feet in circumference, with a wall ten feet thick, composed of massive blocks of dry stone, and with other walls of similar construction. Military earthen works are numerous in all parts of the county. At Carrigeen, near Croom, are the remains

of a round tower fifty feet in height; and there are indications of two others. The ruins of religious houses are very numerous. Adare, Kilmallock, and Askeaton are peculiarly interesting from the number and extent of their ecclesiastical remains. The river Cernaigue alone has the ruins of seven religious houses on its banks. Manister-Nenagh, the chief of these, is the most extensive pile of monastic ruins in Munster. Of the castles of the early proprietors, nearly one hundred still remain. Of these the most remarkable are Croom Castle, Shanet Castle, Cappa Castle, Castle Connel, and Carrick-agonniel. The last-named, a stronghold of the O'Briens, is boldly situated on a basaltic rock rising suddenly from the plain to a height of several hundred feet over the southern bank of the Shannon; it was blown up by General Scravenmore in the war of the Revolution; but although eighty-four barrels of gunpowder were exploded under it, two of the towers are still tolerably perfect. There are several stone circles, and other supposed remains of Druidical worship, throughout the county.

LIMERICK, a city and county of a city, a port, and a parliamentary borough, is situated at the interior extremity of the estuary of the Shannon, 50 miles from the Atlantic Ocean, and 119 miles W.S.W. from Dublin, 52° 40' N. lat., 8° 35' W. long. The population in 1851 was 53,448; in 1861 it had fallen to 44,476, of whom 39,689 were Roman Catholics. There are about 1900 electors in the parliamentary borough, which returns two members to the House of Commons.

Limerick is connected by railway with Dublin and all parts of the country. It is the fourth town in importance in Ireland, and is the capital of the west, as Dublin is of the east, Belfast of the north, and Cork of the south. The city is chiefly built on the county of Limerick side of the river. The island on which the old town of Limerick stands was probably selected as the site of a city from the circumstance of this being the first point at which the Shannon is fordable above its estuary. The island, called King's Island, is about a mile in length, by from a quarter to half a mile in breadth, and lies nearly north and south, having the main stream of the Shannon, about 500 feet in width, on the western side, and a smaller branch, called the Abbey River, of an average breadth of 200 feet, on the east and south. This portion of Limerick is named Englishtown. Another portion known as Irishtown occupies the southern bank of the river, and another suburb called Newtown Perry, entirely of modern erection, occupies elevated ground parallel with the river, below the union of its two branches, and derives its name from the Perry family, who were owners of the land. A suburb called Thomond Gate is situated on the county of Clare side of the river, at the end of Thomond Bridge, which was formerly the only entrance to the ancient city, and was defended by a strong castle. There are five bridges over the river, one of which, the Wellesley bridge, a magnificent structure crossing the harbour, cost 85,000*l*. The streets and houses in Englishtown are said to resemble those of the city of Rouen, but its general appearance is that of decay and misery. The streets of Irishtown are wider and the houses more modern. Newtown Perry in many parts is scarcely inferior to the best districts of

Dublin, with spacious streets, handsome houses, and well-stocked shops.

The most noteworthy public buildings are—the cathedral (founded in 1180, and rebuilt in 1490) a new Roman Catholic cathedral, the fine church of the Redemptorist order, five Protestant churches, four parochial and four conventual Roman Catholic chapels, five dissenting places of worship, several public schools, the county and city court-houses and prisons, the custom-house, Barrington's hospital, fever and lock hospital, district lunatic asylum, Mount St. Vincent orphanage, chamber of commerce, model school, town-hall, flax factory, lace factory, corn and butter markets, and barracks. The manufacture of linen, which had nearly expired, is revived; that of gloves continues, but is not so important as formerly. Limerick is also celebrated for the manufacture of lace and fishing hooks. There are distilleries, breweries, tanneries, foundries, flour mills, a patent slip for vessels of 500 tons, and three ship-building slips. The harbour extends about 1600 yards in length and 150 in breadth, with from two to nine feet at low water, and nineteen at spring tides; which latter enable vessels of 600 tons to moor at the quays. Nearly in the middle of the harbour the Wellesley bridge has a portcullis for admitting vessels. The port is under the control of commissioners. The number of vessels registered as belonging to it in 1866 was 44 (5452 tons). The entries in 1865 were 383 (92,903 tons), and the clearances 285 (64,154 tons). The customs revenue in 1865 was 123,325*l*. The trade of the port—consisting of imports of British manufactures, coal, turf, continental and colonial produce, and exports of corn, meal, butter, beef, and pork—is large, and still increasing. By the inland navigation of the Upper Shannon, and the Grand Canal and Royal Canal, the city has communication with Dublin, as well as with the country, for 230 miles along the course of the Upper Shannon. The corporation of Limerick consists of eight aldermen, and thirty-two councillors, elected by eight wards. The assizes for the county and city are held here, as are also quarter (county) and petty sessions. The mayor holds a Court of Conscience for pleas under 40*s*., and the assistant-barrister a Civil Bill Court for the county and city. The city is the head-quarters of the Limerick or south-western military district.

Limerick lays claim to high antiquity, and is said to have been of some importance as early as the fifth century. It was a royal seat of the kings of Thomond before the Conquest; was in the possession of the Danes for some time, and was afterwards held by the O'Briens, kings of Munster, till the first hostile landing of the English in 1170. From this time, down to 1691, when it capitulated to the troops of William III., under Ginkell, the city had its full share of the vicissitudes and calamities caused by the wars, feuds, and rebellions to which the country was subject.

The bishopric of Limerick, comprising eighty-eight parishes, is now joined with the ancient sees of Ardferret and Aghadoc, thus forming the united bishopric of Limerick, Ardferret, and Aghadoc.

LIMESTONE. This term is applied to a great variety of earthy compounds, in which carbonate of lime is the predominant ingredient. In regard to the chemical composition of limestones, we may notice

that some, as statuary marble, are nearly pure carbonate of lime; others, as the dolomitic rocks of the Alps, contain a certain proportion of carbonate of magnesia; and some are penetrated by bituminous matter, as the black marbles of Yorkshire. Limestones also vary in quality, and become debased by admixture with sand, clay, oxide of iron, pyrites, &c.; so that there is in fact a real gradation from limestone to schist, to sandstone, to shale, to ironstone, &c. Limestones have a crystalline aggregation, as statuary marble, and generally the limestones mixed with primary systems of strata; or they are composed of small crystalline grains, as the magnesian limestone of Mansfield in Nottinghamshire; full of round concretionary parts, as the oolites of Portland, Bath, and Oxford; earthy, as chalk, and some magnesian limestones; or compact, as the lithographic stone of Solenhofen. The beds of calcareous rocks are of every thickness, from a mere lamina to some yards thick. The colours of limestone vary indefinitely. When argillaceous matter is mixed with the calcareous basis of the rock, the colour generally approaches to blue; magnesian and oolitic limestones are often yellow; primary limestone and chalk are generally white; the Tisee marble is red; some of the Derbyshire and Kilkenny marble is black; and there are many-veined and party-coloured marbles, as those of Babilcombe, Sienna, &c. Limestones are rich in organic remains.

LIMIT; LIMITS, THEORY OF. The word limit implies a fixed magnitude to which another and a variable magnitude may be made as nearly equal as we please, it being impossible, however, that the variable magnitude can absolutely attain, or be equal to, the fixed magnitude. Thus the sum of the series $1 + \frac{1}{2} + \frac{1}{4} + \frac{1}{8} + \frac{1}{16}$ approaches nearer and nearer to 2 as the number of terms are increased, but they can never become equal to 2, for the difference, though steadily diminishing, still exists. Under these circumstances 2 is said to be the limit of the sum of the series.

The method of limits is in reality nothing more than one way of evading the use of the word infinite in an absolute sense.

LIMITATION. [STATUTES OF LIMITATION.]

LIMITED LIABILITY. [JOINT STOCK COMPANY.]

LIMMA; in ancient Greek music, may, for all practical purposes, be considered as the minor semitone of the modern scale.

LIMNE'ANS, in French, *Lymnéens*, or more properly, *Limnéens* (λίμνη, *limnē*, 'a marsh, pool, or lake'), Lamarck's name for a family of fresh-water testaceous molluscs, consisting of the genera *Planorbis*, *Limnea*, and *Physa*. The family name now in general use is *Limnæidae*.

Lamarck collected these three genera in the following order: *Planorbis*, *Physa*, and *Limnea*, under one family, his *Lymnéens*, with the following definition:—

Amphibian Trachelipods, generally deprived of an operculum, and having flattened tentacles. They live in fresh water, and come to respire the air at the surface.

Their shell is spirivalve, most frequently smooth on the external surface, and always having the right edge of its aperture sharp, and not reflected.

The *Limnæidæ* are very common in ponds, ditches,

rivers, and streams. They deposit their eggs enveloped in a glairy substance like clear jelly, on the leaves of water-plants, or on stones, but generally on the former, and these are often to be found on the leaves of water-cresses brought to the table. The shells of the *Limnæidæ* are very delicate and fragile, and their external border treacherous. The molluscs have only two tentacles carrying sessile eyes at the internal side of their base; the eyes are never at their summit.

Fossil Limnæidæ.—Fossil *Limnæidæ* occur in various fresh-water formations, both in our island and the Continent, and in some places they are abundant, and some of the species are identical with those yet existing.

LIMNORIA (*Leach*), a genus of marine *Crustacea* belonging to the order *Isopoda* and family *Assellidæ*. This form is, on the one hand, closely related to the well-known fresh-water *Assellus* or Screw, as it is popularly named; and, on the other, to the *Oniscus* or Sceler, so frequently met with in old walls, caves, cellars, among garden rubbish, and other damp places. Only one species belongs to this genus, the *Limnoria terebrans*, so named from its habit of boring into timber and wood-work of all kinds immersed in the sea. It is very small, being seldom met with larger than about two-tenths of an inch. Like all the members of this family, the *Limnoria* can, when touched, roll itself into a ball. The body consists of fourteen segments. The mouth is furnished with a pair of strong mandibles, which it uses in boring. [*ISOPODA*.]

LIMOGES, the capital of the French department of Haute-Vienne, is situated on the summit and slope of a hill, on the right bank of the Vienne, which is here crossed by three bridges, 236 miles S. by W. from Paris, in 45° 49' 52" N. lat., 1° 15' E. long., and has 51,053 inhabitants. It takes its name from the *Lemovices*, a Celtic tribe whose capital it was. By the Romans it was called *Augustoritum*, and under them it was a place of considerable importance. It was taken after a revolt, in 1870, by the Black Prince, who put 3000 of the inhabitants to the sword. The older part of the town consists of narrow and steep streets, with timber-framed houses: the more modern part contains broad and straight streets, and two handsome squares. Of the public edifices the principal are the town-hall, the cathedral of St.-Étienne, a fine Gothic edifice of the thirteenth century; the churches of St.-Michel-des-Lions, and St.-Pierre-du-Queyroix; the episcopal palace, and the beautiful fountain of Aigoulène. The hôtel de ville, bourse, mint, public library of several thousand volumes, the cavalry barracks, the prefect's residence, the theatre, and the hospitals, also deserve notice.

Limoges is the seat of a bishop, whose diocese includes the departments of Creuse and Haute-Vienne; and of a Cour Royale and University Academy, the jurisdictions of which comprehend the departments of Haute-Vienne, Corrèze, and Creuse. In the city are societies of agriculture, arts, and sciences, and a school of commerce; it has an amphitheatre, and various other antiquities. It was once strongly fortified. A great number of books are printed in Limoges; and the manufacture of fine and coarse woollen cloths, paper, porcelain, and crucibles, is important. Flannel, cotton handkerchiefs, glue, nails,

woollen yarn, room paper, articles in papier-mâché, &c., are also made. There is, besides, a considerable commerce in corn, chestnuts, wine, brandy, liqueurs, iron, copper, tin, kaolin, &c.

LIMO'NIA, a genus of plants of the natural family of *Aurantiaceæ*. Most of the family abound in essential oil, and the leaves of some of the *Limonias* are fragrant. The fruit, though small, of *L. acidissima* and *L. crenulata* is very acid. [*CITRUS*.]

LIMOUSIN, one of the old French provinces which now form the departments of *CORRÈZE* and *HAUTE-VIENNE*. Limousin was united to the French crown by Henry IV., who inherited it from his mother, Jeanne d'Albret.

LIMOUX. [*AUDE*.]

LIMPET (*Patella*), the name of a genus of well-known gasteropodous mollusca. The British limpet (*Patella vulgata*) has not fewer than 160 rows of teeth, with twelve teeth in each row. The limpets are found adhering to rocks and stones which lie between tide marks; they are left dry twice a day. They are used by fishermen as bait.

LIM'ULUS (Lat. *limus*, 'mud'), a genus of *Entomostraca*, commonly known by the name of the King Crab. It is furnished with six pairs of prickly feet, and a long, sharp-pointed tail, sometimes sufficiently strong to be used by savages as a spear-head.

LINA'CEÆ, a small natural order of plants, related to *Cistaceæ*. The whole order contains only two genera, *Linum* and *Radiola*: the former comprehends many species, the most important of which is common flax, *Linum usitatissimum*, the woody tissue of whose stems is so valuable for its toughness and fineness, and whose seeds furnish linseed oil.

LINACRE, or *LYNACER*, THOMAS, one of the most eminent physicians and scholars of his age, was born at Canterbury about 1460. He received his first education in his native city, under William Tilly, or De Selling, and afterwards entered at Oxford, where he was chosen a Fellow of All Soul's College in 1484. He studied also at Bologna, and afterwards at Rome, under Politian and Demetrius Chalcondyles. He applied himself particularly to the works of Aristotle and Galen, and is said to have been the first Englishman who made himself master of those writers in the original Greek. He also translated several of Galen's treatises into elegant Latin, and with Grocyn and William Latimer undertook a translation of Aristotle, which was never completed. On his return to England, he was created M.D. at Oxford, a degree he had taken at Padua, and he gave temporary lectures in physic, and taught the Greek language at Oxford. His reputation became so high that King Henry VII. called him to court, and intrusted him with the care both of the health and education of Prince Arthur.

Linacre now stood at the head of his profession, and showed his attachment to its interests by establishing two lectures on physic in the University of Oxford, and one in that of Cambridge. He may also be considered the founder of the College of Physicians in London; for in 1518 he obtained letters-patent from King Henry VIII., constituting a corporate body of regularly bred physicians in London, in whom was vested the sole right of examining and admitting persons to practise within the city and seven miles round it, and also of licensing practitioners through-

out the whole kingdom, except such as were graduates of Oxford or Cambridge, who by virtue of their degrees were independent of the college, unless within London and its precincts.

Highly as Linacre was esteemed in his profession, he became desirous to change it for that of divinity, or rather to combine the two pursuits. In 1518 we find him possessed of a prebend in the cathedral of York, where he was also for a short time precentor, and he had other preferments in the church. He died October 20, 1524, and was buried in St. Paul's Cathedral, London.

Besides his translation of Galen, he published a translation of Proclus, 'De Sphæra,' which was printed in the 'Astronomi Veteres' of 1499. Of his other works one of the most learned was his treatise 'De Emendata Structura Latini Sermonis libri sex,' printed at London immediately after his death in 1524, and frequently reprinted.

LINARIA, a genus of plants belonging to the natural order *Scrophulariaceæ*. *L. cymbalaria*, the Ivy-leaved Toad-flax, is a native of Europe, chiefly on old walls. It grows abundantly in Italy and Sicily, and is found in Great Britain. There are several varieties of this species. *L. elatine* is a native of Europe and Africa, and is found in chalky corn-fields in Great Britain. *L. spuria*, *L. minor*, *L. repens*, *L. pelerissima*, and *L. Italica*, are all natives of Great Britain. *L. vulgaris* in some places is called 'Butter and Eggs.' Gerard names it Wild-flax, Toad-flax, and Flax-weed. It abounds in an acrid oil which is almost empyreumatic. Taken inwardly, it induces nausea. It has been advised in dropsy, but most authorities disapprove of it. When united with milk, the juice is a poison to flies. The whole of the species of Linaria have an elegant appearance, and are therefore suited for flower gardens.

LINCOLN. [LINCOLNSHIRE.]

LINCOLN, ABRAHAM, President of the United States of America during the most momentous period of their history since the time of Washington, was the grandson of Abraham Lincoln, killed by Indians in 1784, and the son of Thomas Lincoln, of Virginia, by his wife, Nancy Hanks. He was born, February 12, 1809, in Harden County, Kentucky. His father, Thomas Lincoln, when the young Abraham was about eight years of age, removed with his family to Spencer County, Indiana. There for the next twelve years Abraham shared in the ordinary pursuits of a settler, living in the log hut which they had built when they first came to the neighbourhood. He had not, however, during all these years the guiding hand of his mother, for she died shortly after they took up their residence in Indiana. In course of time, a Mr. Crawford came to settle in the neighbourhood, and opened a school in his own cabin, and Abraham Lincoln was his pupil. Abraham was a youth of manifold qualifications: he had perseverance, a desire for knowledge, truthfulness, and earnestness. The books which he loved to peruse at this period were Bunyan's 'Pilgrim's Progress,' 'Æsop's Fables,' a life of Henry Clay, afterwards his model of an upright statesman; and Weem's 'Life of Washington.' When he was nineteen he made a trip to New Orleans in a flat-boat, with the son of one of his neighbours, with a cargo for the New Orleans market. In addition to a long voyage down

the river Ohio, which bounds Indiana on the south, the young voyagers had at least 1000 miles of the Mississippi to traverse before they arrived at their destination. The voyage was successful, and raised the character of Abraham Lincoln in the vicinity as a youth of energy and promise. In 1830, when about twenty-one years of age, he migrated once more with his father to Decatur, Illinois. Here he helped to build the family log-hut; and with a single assistant performed the feat of splitting 3000 rails in a day, which obtained him the popular *soubriquet* of the 'Railsplitter.' He afterwards started on his own account, hiring himself out first of all as a farm hand, and occasionally acting as a clerk in a store. When the war with the Indians broke out in 1832, commonly called the Black Hawk War, Mr. Lincoln was elected to the command of a company of volunteers. After his military career, Lincoln kept a store; and then took to the business of a surveyor. In 1834 he was sent to the local Legislature, and during the time the House was not sitting he applied himself with vigour to the study of law. In 1836 he obtained a license to practise; and in 1837 went to Springfield, the chief town in Illinois, and commenced as a lawyer, in partnership with the Hon. John F. Stuart. He rose rapidly in public favour, and is said to have been very successful as an advocate in jury trials. In 1846 he was returned to Congress, and took his seat as the only Whig member from Illinois. He continued to belong to Congress till 1849. The Whigs were the forerunners of the present powerful Republican party, the chief point of difference being that of slavery. Lincoln was for freedom, and on that ground opposed the Mexican war. He supported a bill abolishing slavery in the district of Columbia. When the Wilmot proviso was discussed to exclude slavery from those territories which had been captured from Mexico, Mr. Lincoln voted for the proviso; and he afterwards stated that, in one way or another, he had cast his vote about forty times in favour of the abolition of slavery. In 1849 he stood, and was defeated, for the office of United States senator for Illinois, and consequently remained at home from that period until 1854 in the practice of his profession. In that year the Kansas Nebraska Bill was passed by the slaveholding party, aided by some of their supporters in the North. Mr. Stephen A. Douglas stood for United States senator from Illinois, and Mr. Lincoln opposed him; the two champions ultimately holding seven joint debates in different towns of the state for the purpose of informing the people of the grounds of difference of policy upon which they were called to decide. Upon his discussions with Douglas, however, the eyes of the whole country were fixed, and the ability and quaint humour which Mr. Lincoln exhibited, and the success which he gained for the party, made him very popular among the Republicans. The immediate practical question which then agitated the people, and which came to be the turning-point of the presidential election of 1860, was whether or not slavery ought to be permitted in the new territories, as one by one they were included in the Union. Mr. Lincoln believed that slavery ought to be excluded from the territories, although he did not see his way to interfere with slavery in those states where it existed. The Republican Convention, which met at Chicago,

nominated Mr. Lincoln as their candidate for the presidency. The contest lay between him and Mr. Seward. The canvass was carried on with the usual good humour in the North, but amid threatenings and mutterings in the South in the prospect of their defeat. The polling resulted in the return of Mr. Lincoln—the numbers being, for Lincoln, 1,857,910; for Douglas, 1,291,574; for Breckenridge, 850,082; and for Bell (a Whig of long standing), 646,124. The election, in 1860, of Mr. Lincoln was hailed with delight by the people of the Northern states, and when he proceeded to Washington to execute the functions of president, the whole country watched his progress with intense satisfaction. He was installed in the president's chair, 4th March, 1861. His election by a sectional vote and on a sectional issue hostile to the South, was followed by the secession of eleven Southern states, and a war for the restoration of the Union. Mr. Lincoln's policy was to woo the South to submission to the constitutionally-expressed will of the people by every argument which would be supposed to have weight with American citizens. His appeal was vain, and he had no choice but to enforce the laws and to use all the powers of the Constitution for the suppression of the South. For the details of the terrible civil war that followed, the reader is referred to the article UNITED STATES. As a military measure, Mr. Lincoln proclaimed (January 1st, 1863) the freedom of all slaves in the rebel states, and afterwards the absolute freedom of the negroes throughout the country. He was re-elected as President in 1865, and after conducting the war to a successful issue, and witnessing the complete defeat of the Confederate or Southern forces, he fell the victim of one of the foulest and most daring acts of assassination whose record has ever disgraced the pages of history. President Lincoln died on the 15th April, 1865, from the effects of a shot fired at him by John Wilkes Booth, in Ford's Theatre, Washington, on the previous evening. He left a widow and family. His moderate views, high principle, and homely wisdom, had obtained for him the respect of the civilized world; and his cruel death, at the moment when he was engaged in attempting to heal the wounds made by civil war, was profoundly lamented.

LINCOLN COLLEGE, Oxford, was founded in 1427 by Richard Flemming, bishop of Lincoln, for a rector and seven fellows; it was afterwards greatly augmented by Thomas Rotherham, bishop of Lincoln, who added five fellowships, and gave a body of statutes to the foundation, in which he limited the election of the fellows to the old dioceses of Lincoln and York, with the exception of one to the diocese of Wells. This was in 1479. Lord Crewe, bishop of Durham, in 1717 made an addition to the emoluments of the rector and fellows, and in 1718 endowed twelve exhibitions of 20*l.* a year a-piece. The scholarships and exhibitions received a further augmentation at a later time by the will of Richard Hutchins, D.D., rector from 1755 to 1781.

The original limitations were abolished by authority of Parliament (17 & 18 Vict.). The foundation at present consists of a rector, twelve fellows, and eighteen scholars. The buildings of Lincoln College retain much of their original character. They consist of two quadrangles, besides six sets of rooms

erected at a later period. The largest quadrangle includes the rector's lodgings, library and hall, built in the fifteenth century; the library was originally the chapel. The smaller court was in part built about 1612 by Sir Thomas Rotherham. The present chapel, upon its south side, was built in 1631 by Archbishop Williams. The windows are rich in painted glass procured by the archbishop from Italy in 1629. In 1818 the whole front of the college was repaired.

LINCOLNSHIRE, an English county, is bounded N. by the estuary of the Humber, N.W. by Yorkshire, W. by Nottinghamshire, S.W. by Leicestershire and Rutlandshire, S. by Northamptonshire, S.E. by Cambridgeshire and Norfolk, and E. by the German Ocean. The greatest length N. to S. is 75 miles; the greatest breadth E. to W. is 52 miles. It is comprehended between 52° 39' and 53° 45' N. lat., and between 0° 22' and 0° 58 W. long. The population at the census of 1861 was 412,246—204,644 males, and 207,602 females—being an increase of 5024, or 1 per cent. since 1851. The number of inhabited houses in the county was 86,626; uninhabited, 4289; building, 530. The total area is 1,775,457 acres, of which nearly 1,300,000 are said to be cultivated, and about 450,000 inclosed fen land.

Coast-line and Surface.—The coast, from the Welland to the Humber, forms a tolerably regular curve convex to the sea, and is low and marshy except about Clea Ness, near Grimsby, where it rises into cliffs. A belt of sand of varying breadth skirts the land. From the mouth of the Welland to that of the Nene the coast is so low as to require the protection of a sea-wall or bank. The estuary of the Wash is occupied for the most part by sand-banks, dry at low water. Between these banks the streams which flow into the estuary have their channels; and two portions of deeper water, named Boston Deepes and Lynn Deepes, also occur between them.

A considerable part of Lincolnshire consists of alluvium, constituting a vast extent of flat or marsh land, from the border of which the subjacent strata rise and form comparatively elevated tracts. The alluvial soil occupies nearly the whole of the coast; and in some places it extends half across the width of the county.

From Barton-upon-Humber, to Burgh, near Wainfleet, stretches a line of chalk downs, called the Wolds of Lincolnshire. These downs sink on the north and east beneath the alluvium described above. Along the coast north and south of Saltfleet are natural outlets of water called provincially 'blow wells,' deep circular pits, which furnish a continual flow of water, and are vulgarly reputed to be unfathomable; they are presumed to communicate with the chalk. The green-sand forms a narrow belt, skirting the chalks on the west side of the Wolds; and the iron-sand occupies a narrow belt adjacent to it. Westward of the iron-sand extends a wide flat, occupied mostly by the Oxford clay; this district forms a large central valley separating the Wolds, with the adjacent hills, from the higher grounds formed of the oolitic strata, which extend southward through the county from the marshes which line the Humber. These higher grounds form part of what have been termed the Stonebrash hills, and separate

the valleys of the Ancholme and the Lower Witham from those of the Trent and the Upper Witham. The remaining part of the county is occupied by the lias, except a little of the new red sandstone in the north-west corner.

Hydrographic System.—The Trent, for about 16 miles, separates the counties of Lincoln and Nottingham; from below Gainsborough to its junction with the Yorkshire Ouse, its course of 19 miles is almost entirely within the borders of Lincolnshire. This river is navigable throughout that part which belongs to this county. The Idle, the Bykerdike, and the Torne flow into the Trent. The Ancholme rises near Spirdlington, and flows past Bishop Briggs to the Humber near Barton; there is a straight artificial cut of 20 miles to aid the navigation. The Tetney is formed by two streams which rise near Market Rasen, and flows into the German Ocean between Grimsby and Saltfleet. The Ludd rises near the south-west escarpment of the chalk range; it is formed by the junction of two or three brooks which unite above Louth and flow north-east into the German Ocean by several arms. The Louth navigation consists partly of this river and partly of an artificial cut. The Withern flows into the German Ocean at Saltfleet, and the Steeping at Spilsby.

South of Wainfleet the fen district commences: and from the extensive system of draining that has been carried on, the hydrography of the county becomes very complicated. The rivers have in several places been diverted from their natural beds, and now flow in artificial channels in direct lines, or are connected with artificial cuts, forming a very complete scheme of intercommunication.

The Witham, the most important river in the county, rises near the village of Thistleton, just within the border of Rutlandshire, and flows past Grantham, Lincoln, and Tattershall to Boston, below which town it flows into the Wash. The length of the Witham is about 80 miles, during the course of which it receives the waters of the Brant, Langworth, South Beck, Bain, Sleaford River, and the Waring, Scrivelsby, and Enderby Becks. Many of these minor streams are united by artificial cuts. The Welland rises in Northamptonshire, and flows past Stamford, Deeping, Crowland, whence there are two branches, the Old and New Welland, to the Wash. The Glen rises near Grantham, and flows into the Wash near the mouth of the Welland.

A general account of the great fen district of England, and of the changes which it has undergone, is given elsewhere. [BEDFORD LEVEL.] The northern fens are described in AXHOLME. The artificial cuts or drains are very numerous; they are called by the several names of 'cuts,' 'drains,' 'leams,' 'doves,' 'becks,' 'eans,' and 'dykes.' The chief among them, in this county, are the Car Dyke, the South Forty-Foot, the North Forty-Foot, the East Fen Drain, the West Fen Drain, the Old and New Hammond Becks, and the Shire Drain.

Of navigable canals, besides the Ancholme, Louth, Horncastle, Sleaford, Bourn, and other navigations, there are only two. One of them, the Foss Dyke, is probably a Roman work, and appears to have been used for navigation previous to the Conquest. Henry I. had it cleaned out and the navigation improved. It extends from the Trent to the Witham.

The other canal is the Stainforth and Keadby Canal, which connects the Trent with the Don.

Soil and Agriculture.—The soil varies greatly in different districts. In some places it is rich and productive, and in others so poor as to weary the patience and industry of the most persevering. But the grazing land in this county cannot be surpassed in its capabilities for fattening cattle; and some of the drained fens and warp-lands along the rivers possess a high degree of fertility when cultivated. The finest pastures are fed off by horses, which are fatted for the markets; but horses soon deteriorate the grass, while sheep improve it. Very little hay is made in the county: the grass is mostly eaten in a green state.

The lands which have been reclaimed from the sea by banking and draining are mostly laid out in large farms, which require a considerable capital. In other parts of the county there are many small properties, cultivated by the owners, and kept with great neatness. Fish is much used as a manure. Ground bones are used very abundantly on the light sands.

On the richest fen lands the most profitable rotation consists of the following crops:—1, Cole fed off with sheep; 2, oats; 3, beans; 4, wheat; 5, clover; 6, wheat. In some heavy soils the Essex rotation is adopted:—1, fallow; 2, barley; 3, beans; 4, wheat; and this, alternated with the others, answers well on rich land. For the poor sands there is no system so advantageous as that of raising turnips, and feeding sheep with them on the land where they grew.

There is some wood cultivated in the neighbourhood of Boston on rich warp-land; some sainfoin grown on the chalky soils, and lucerne on the richer. Cabbages and carrots are cultivated to a considerable extent; the former on the heavy clays, and the latter on the light and deep sands.

One of the most effectual improvements on land by the side of rivers in which the tide flows rapidly is that of warping; or in other words retaining the water on the land until it deposits a layer of sand and mud. The warping is effected by letting in the water of the rivers, which have a muddy current, by artificial channels and sluices, and retaining it there till low water. The river Humber carries off, in its course over various soils, all the finer particles which are too light to be immediately deposited. These consist of every kind of earth and portions of vegetable and animal matter, and are in such quantity that a layer one-tenth of an inch in thickness is often deposited between one tide and the next. Thus in a very short time a new soil is formed of any depth which may be desired, provided the land lies below the level of the river at high tides. Besides creating a soil, the warping fills up all inequalities, and a perfect level surface is produced. The soil thus produced is of extreme fertility.

In a county which contains such rich pastures it is of great importance that the breed of cattle and sheep be of the most profitable kind; accordingly we find that no county possesses finer breeds of horses, oxen, and sheep. There are not many dairies in Lincolnshire: breeding and fattening are considered more profitable and less troublesome. There is, however, some excellent cheese made of the Stilton kind.

Divisions, Towns, &c.—Lincolnshire has long been divided into three 'parts,' as they are termed, Lindsey, Kesteven, and Holland. Lindsey is by far the largest, and comprehends all that part of the county which lies north-east of a line drawn from Clifton-upon-Trent to Lincoln, thence by the Witham to near Boston, and from just above that town to the sea between Boston and Wainfleet. The name Lindsey, like that of the county, is derived from Lindum, the Roman name of Lincoln. Kesteven comprehends the south-western part of the county, and Holland (or Hollow-land) comprehends the remainder, including the greater part of the fens. Lincolnshire is further divided into wapentakes, hundreds, and soles. It is in the diocese of Lincoln, and in the Midland Circuit, the assizes being held in Lincoln. For parliamentary purposes the county is divided into North Lincolnshire and South Lincolnshire, each of which returns two members to Parliament; besides which, the city of Lincoln, Stamford, Grantham, and Boston return each two members, and Great Grimsby one—total, thirteen. The number of voters on the county register in 1866 was 21,632; 12,372 in the northern division; and 9260 in the southern.

The county is divided into 33 hundreds, and 629 parishes. It is famed for the number and beauty of its ancient parish churches.

The following are the principal towns, with the population of each in 1861:—

Alford ('Old-ford') is 22 miles N. by E. from Boston, and situated near the head of a small stream which flows into the sea. The town consists chiefly of one street. Population of the parish, 2658.

Barton-upon-Humber, a market town on the south side of the Humber, 33 miles N. by E. from Lincoln, is an ancient town, and at the time of the Norman Conquest was one of the principal ports of the Humber. It is now the place where the northern road passes the Humber to Hull; and the improvements which have been made in the ferry have rendered it a considerable thoroughfare. The town contains two large churches, one of which is very ancient. A thriving trade in corn is carried on; and bricks, tiles, ropes, and sackings are extensively manufactured. Population, 3797.

Bolingbroke is a small market town, 8 miles N. from Boston. There are a few remains of an ancient castle which belonged to John of Gaunt, and from which his son Henry IV. took the surname of Bolingbroke. Population of the parish, 1018.

Boston. [BOSTON.]

Bourn is a market town on the road from London to Lincoln, 36 miles S. by E. from Lincoln. It consists chiefly of one long street of modern houses. In the centre of the market-place is an ancient town-hall, said to have been built by the great Lord Burghley, a native of the town. The parish church is large. Wool-stapling and tanning are carried on, and the town has some trade in leather and wool. There is a navigable canal communicating with the river Glen. Population of the parish, 3730.

Crowland, or Croyland, is near the south border of the county, 42 miles S. by E. from Lincoln. Croyland Abbey was a rich monastic establishment. There are some remains of the church. The village is surrounded by fens. The market has been removed to Thorney. Population of the parish, 3148.

Gainsborough, an ancient market town and seaport, is situated on the eastern bank of the Trent, 15 miles N.W. by N. from Lincoln. The town consists chiefly of one street running parallel with the river, which is here crossed by a substantial stone bridge. There is a town-hall, beneath which is the gaol. By means of the Trent, which falls into the Humber about 20 miles below the town, vessels of 200 tons' burthen can come up to the wharfs, and the town has inland communication by canals, and a railway extends from Gainsborough to Great Grimsby. The population of the town is 6320; of the entire parish, 7339. The number of vessels which entered the port in 1864 was 177 (9083 tons), and the clearances 283 (13,045 tons). The customs revenue in 1865 was 90611.

Grantham, a parliamentary and municipal borough, is situated on the west bank of the Witham, 23 miles S. by W. from Lincoln. The church is a beautiful specimen of the Gothic architecture of the thirteenth century, with a spire which is much admired for its elegance and loftiness. There is a guild-hall, a gaol, a house of correction, and a free grammar-school founded in 1528. Grantham is connected with the Trent by means of a canal 30 miles long. The trade is chiefly in corn, malt, and coals. The municipal borough is governed by four aldermen and twelve councillors: population, 4954. The parliamentary borough returns two members: population, 11,121. The number of registered electors in 1866 was 755.

Grimsby. [GRIMSBY.]

Holbeach is a market town, 12 miles S. by E. from Boston. The church is large and handsome. Population of the parish, 4956.

Horncastle is a market town, 17 miles W. from Lincoln. The town has been much improved of late years, and contains many well-built houses. Part of the church is ancient. Corn and wool are the principal articles of commerce, which has been much promoted by opening the Horncastle navigation from this town to the Witham. Population of the parish, 4944.

Lincoln, the capital of Lincolnshire, a city and a county of a city, a municipal and parliamentary borough, is situated on the north bank of the Witham, 134 miles from London by the road. It was a place of considerable importance under the Romans, and also in the time of the Saxons.

The city is built on the southern slope and at the foot of a hill, on whose summit stands the cathedral. It is irregularly laid out; the principal street is along the road from London to Barton-upon-Humber, which traverses the entire city, crossing the Witham by a bridge, and running up the hill crowned by the cathedral. This street also extends a considerable length south of the Witham. The most interesting of the public buildings is the cathedral, which has two transepts, a central tower at the intersection of the larger transept, and two western towers. It has been erected at different periods. The predominant style is the Early English. Fuller remarks that the floor of this church is higher than the tops of most churches. The nave is very fine, and the piers in this part are peculiarly rich. The entire length, in the interior, is 482 feet, the height of the vaulting of the nave is 80 feet. The new bell, which is

larger and heavier than the old bell called Tom of Lincoln, is 6 feet 10½ inches in diameter at the mouth, and weighs 5 tons 8 cwt.—the old one weighed nearly a ton less. There are several parish churches. The remains of the castle stand on the hill, west of the cathedral: they consist chiefly of the outer walls and the gateway tower. The site of the interior of the castle is occupied by the county gaol and court-house, which were rebuilt some years ago by Sir R. Smirke. The guild-hall dates from the reign of Henry VIII. Lincoln abounds in monastic and other remains of ancient architecture. There are several ancient gateways, as Newport Gate, whose arch is Roman, the Chequer or Exchequer Gate in the Cathedral Close, and the Stonebow in the High Street. The remains of John of Gaunt's Palace, and of a building called John of Gaunt's Stables, present some interesting Norman and Early English features.

The chief trade is in flour, and there are some extensive breweries noted for their ale. The county assizes are held here. Its horse, sheep, and cattle fairs are of great importance.

The municipal borough is divided into three wards, and is governed by six aldermen and eighteen councillors. The parliamentary borough returns two members: the number of voters in 1866 being 1713. The population within the municipal and parliamentary limits (which are co-extensive), is 20,999.

Louth, a market town and municipal borough, is situated on the bank of the little river Ludd, 25 miles N.W. by W. from Lincoln. The church is one of the finest in the county; it has a lofty and elegant tower, surmounted by a spire. The Louth navigation extends from the town to the sea at the mouth of the estuary of the Humber. The municipal borough is divided into two wards, and is governed by six aldermen and eighteen councillors. Population of the parish, 10,667.

Sleaford, called *New Sleaford*, to distinguish it from the adjacent village of Old Sleaford, is a market town, situated on the little river Sleas, 16 miles S. by E. from Lincoln. The town has been much improved of late years, and is well paved and drained. The church is large and handsome, with a tower surmounted by a lofty spire. The Sleaford Canal is cut from this town to the river Witham. Population of the parish, 3467.

Spalding, a market town, is situated on the left bank of the river Welland, 15 miles S.W. by S. from Boston, of which port it is a member. The Welland is navigable for vessels of 60 or 70 tons up to the town. This town is in the fen district, but is well drained and clean. There is a town-hall, a gaol, a union workhouse, a small theatre, and a church with a fine tower and spire. Population of the parish, 8723.

Stamford, a municipal and parliamentary borough, stands on the left bank of the river Welland, 40 miles S. from Lincoln. A stone bridge of five arches crosses the river, and connects Stamford with a suburb in the bordering county of Northampton. The town is ancient, and the streets are irregularly laid out, but are paved and lighted with gas, and most of the houses are built of freestone and covered with slate. The Welland is made navigable to the town for boats and small barges. There are six churches in Stam-

ford, and one in the suburb on the right bank of the river. Most of the architecture of these churches is ancient, and some of it very fine. Some interesting monastic remains exist in and near the town. There are a town-hall, gaol, theatre, infirmary, several places of worship for dissenters, and numerous schools. The Great Northern Railway passes through Stamford. The municipal borough is divided into two wards, and is governed by six aldermen and eighteen councillors. The parliamentary borough returns two members, there being 512 electors in 1866. The parliamentary and municipal boundaries are conterminous, the inhabitants numbering 8047.

History and Antiquities.—At the time of the Roman conquest Lincolnshire constituted part of the territory of the Coritani. In the division which the Romans made of Britain it was included in the province of Flavia Cesariensis.

Under the Saxons, Lindsey, a name which perhaps applied to a district equal to the modern county of Lincoln, appears to have been a subordinate state dependent upon the kingdom of Mercia. Under the Danes it suffered greatly. The narrative of their ravages, given in the pages of the apocryphal Ingulfus, is interesting, and if its authenticity could be depended on would throw considerable light upon the historic darkness of the period. The county passed permanently into Danish hands about 877; it constituted part of the territory of the Danish burghs of Lincoln and Stamford, and was included within the boundary of the Danelagh (the Danish jurisdiction), as settled by the treaty between Alfred and Guthrun the Dane. In time, however, the Danish and Anglo-Saxon population became amalgamated, and the whole district passed under the supremacy of the Anglo-Saxon crown.

In the civil war between Stephen and the Empress Maud Lincolnshire was the scene of frequent contests. In the broils in which Henry II. was involved with his children, one of the Mowbrays, who had a castle in the Isle of Axholme, and was an adherent of the insurgent Prince Henry, was compelled to submit to the Lincolnshire men. In the civil war of the barons with John and his son Henry III., Lincoln was signalized by a second battle, which seated Henry III., yet a boy, securely on his throne. In the latter part of his reign, when troubles had again broken out, Axholme became once more the refuge of the disaffected. In the civil war of the Roses Lincolnshire does not appear to have suffered; but in the reign of Edward IV. an insurrection occurred in the county, in which the Lincolnshire men were defeated with great loss. At the time of the Reformation they again broke out into rebellion upon the suppression of the monasteries in 1536; but the insurrection was soon crushed.

In the civil war of Charles I. this county was the scene of several important events; engagements were fought, in 1642–3–4, at or near Grantham, Ancaster, Gainsborough, Horncastle, and Lincoln.

Of the ecclesiastical and baronial edifices which were erected between the Conquest and the Reformation, Lincolnshire contains many admirable specimens, especially churches. The cathedral of Lincoln, and the churches of Louth, Sleaford, and Spalding, are among the principal.

Of monastic edifices there are several remains. Of

Barling's Abbey part of a wall and some fragments of columns are extant. Of Thornton Abbey, the gate-house, which formed the western entrance, is yet tolerably entire; four handsome hexagonal towers form the four angles of this gate-house. A spacious room, probably the refectory, and an adjoining room with recesses in both ends, the abbey church, and a portion of the octagonal chapter-house, are also standing. Of Bardney Abbey, Kirkstead Abbey, Revesby Abbey, Haverholme Priory, Temple Bruer, and Croyland Abbey, some portions remain.

Sir Isaac Newton was born at Woolsthorpe, near Grantham, and John Wesley was a native of Epworth.

LINCOLN'S INN, one of the four English Inns of Court, having the exclusive right of calling persons to the English bar, or rather to the degree of barrister-at-law. It became an Inn of Court in 1310, occupying premises which had belonged to the earl of Lincoln; hence its name. The other Inns of Court are the Inner Temple, the Middle Temple, and Gray's Inn. [INNS OF COURT.]

LINDLEY, JOHN, an eminent English botanist, was born on the 5th February, 1799, at Catton, near Norwich, where his father kept a nursery garden. In early youth he evinced a strong partiality for botanical studies, and published in 1819 a translation of Richard's 'Analyse du Fruit.' Soon afterwards, his botanical papers in the 'Transactions' of the Linnæan Society having attracted favourable attention, he removed to London, and became assistant-secretary to the Horticultural Society. He recommended the classification of plants on the natural system in his great work on the 'Vegetable Kingdom,' published in 1846, which is now recognized as a standard authority. He also devoted himself to the popularization of botany, and in furtherance of this admirable object produced his 'School Botany,' 'Ladies' Botany,' and other lucid and instructive treatises. For many years he was editor of the *Gardener's Chronicle*, which he conducted with great ability. While engaged in these multifarious labours he was diligently employed, as a practical botanist, in describing new species of plants, on which he wrote a large number of papers for various botanical publications. From 1829 to 1860 he was professor of botany at University College, London. He was a Ph.D. of Munich, a member of several foreign scientific bodies, and a Fellow of the Royal Society, whose gold medal he received, in 1858, as a recognition of his services to botanical science. Dr. Lindley died November 1, 1865.

LINDSAY, SIR DAVID, was born about the end of the fifteenth century, at the family seat of 'The Mount,' in Fifeshire, whence he is commonly called Sir David Lindsay of the Mount. In the year 1512 he was appointed servitor, or gentleman usher, to the young prince of Scotland, afterwards James V. His duties seem to have been of the most servile kind—he had not only to attend the person of the infant prince, but practised the craft of nursing.

He is the authority on which his kinsman, Lindsay of Pitscottie, in his 'Chronicles of Scotland,' describes a spectral apparition which, in 1513, appeared to James IV. in the church of Linlithgow, and warned him against that campaign which terminated in the battle of Flodden. Sir David professed to have seen the apparition approach and vanish, and described

him as 'ane man clad in a blue gown, beltit about him with a roll of linen cloth, a pair of bootikins on his feet to the great of his legs, with all other clothes conform thereto.'

The 'Dream,' supposed to be the earliest of his writings, appeared in 1528. His other principal pieces are—'Complaint of the King's Papingo;' 'Complaint of John the Commonweil;' 'History of Squyer Meldrum;' 'The Monarchie;' and 'The Play, or Satire, on the Three Estates.' He particularly excelled in his attacks on the priesthood and the corruptions of the court; and after the Reformation his name was long popular as that of a Protestant champion. 'The Satire on the Three Estates' stands half way between the early 'Mysteries' and the dramas of the latter part of the sixteenth century. It was sometimes acted in the open air. Lindsay held the office of Lord Lyon King at Arms. In 1537 he had the task of preparing some masques or pageants to celebrate the arrival of Mary of Guise, queen of James V. The time of his death is not known, but he is said to have been alive in 1567.

LINE, a term used in military language, to distinguish the ordinary regiments of cavalry and infantry from the Guards, Artillery, and Engineers. They are so called from the fact of their usually constituting the 'line of battle.'

LINE. [SOLID, SURFACE, POINT.]

LINE SYSTEM. [PRINTING.]

LINEN MANUFACTURES. The textile fibres of the flax plant, twisted into threads and woven into an interlaced network so as to produce a compact fabric, have been employed from the most remote periods as a material for clothing. The production of linen occupied an important place among the manufactures of ancient Egypt. The sacred writings abound with allusions to it, and Herodotus and other authorities frequently refer to the skill which the Egyptians had acquired in weaving fabrics of fine linen, and the enormous quantities in which they were prepared both for home use and foreign exportation. In Egypt the priests were obliged to clothe themselves in linen garments; and microscopic examination of the bandages with which they wrapped the bodies of the dead, show that they were composed of the same material. These bandages have been found to consist of linen of every description of quality, from the 'fine linen' resembling the finest lawn of the present day to a coarse fabric like sacking. The weaving processes employed in the manufacture were evidently not so perfect as the spinning. The webs are usually found to consist of scarf-like pieces about six yards long, and the whole length of the web was probably stretched in a frame as at present by the native manufacturers of the East. The finer fabrics had a twilled appearance, owing to the weft rising on the surface from the looms employed not being capable of light weaving. In a fragment of mummy cloth given by Belzoni to Mr. Thompson, of Clitheroe, the warp contained 90 threads to an inch, the weft only 44. Mr. Thompson ascribed this peculiarity to the difficulty of getting in the weft when the shuttle was thrown by hand. In modern cloths the proportions of warp and weft are nearly equal. A specimen of cloth taken from the body of a mummy in the museum of the Natural History Society of Belfast, was lately submitted to

the examination of a flax merchant, who reported that under the 37-inch glass used by linen merchants 'it counted 17⁰⁰ in the warp and 9⁰⁰ in the weft, and was composed of yarn evenly and well twisted. The flax used was fine in quality, and prepared for spinning in the most careful manner. The warp is about No. 50 and the weft about No. 80. The fabric is not one that would be woven at the present day, as for a 17⁰⁰ linen about 90 warp and 110 weft would now be used.' The Egyptians had the art of introducing into the edgings of their fine linen threads of blue and fawn colours, dyed in the yarn, and some of the cloths are found with broad borders dyed blue, such as are worn at the present day in Nubia, and manufactured by the successors of the ancient weavers of Egypt. In the early times of Greece and Rome linen was regarded rather as an article of luxury than for common use, and confined to female dress; but as civilization and refinement advanced, its value as a healthy material for clothing became more generally recognized, and we find that under the emperors, the Romans had become manufacturers, as well as large importers of the more delicate fabrics of the looms of the East.

The spindle and distaff, such as are to be seen represented on the walls of the tombs of ancient Egypt, and to which there are so many references in the Old Testament, were until comparatively modern times the sole instruments employed in preparing the flax fibres for the weaver. The introduction of the common hand-spinning wheel was the first departure from patriarchal methods, and until about the end of the eighteenth century all the flax fibre produced in Europe was spun by its simple machinery. At that period the production of linen in those countries, as in some parts of Europe at the present day, was merely a rural manufacture of a purely domestic character. The farmer not only cultivated the flax crop but steeped and dressed the fibre, the female members of his household plied the wheel, while his sons wove the delicate threads into brown linen. Improvements, however, were going forward in every department of industry, and the ingenious application of automatic machinery by which Hargreaves and Arkwright had revolutionized the process of cotton spinning, was in 1787 brought to bear by two Durham mechanics, Kindrew and Porthouse, in the manufacture of flax. The earliest attempts in England were made at Darlington, and works were subsequently erected at Leeds, which has now, mainly through the persevering exertions of the Messrs. Marshall, become the head-quarters of the flax trade of England.

In Ireland the manufacture of linen claims the most remote antiquity. Even at an early period the linen merchants of Ireland appear to have found a market for their goods, as at present, in the great towns of England. In 1272 we find Irish linen at Winchester, and about the same period the ancient poem on 'The Battle of Down,' describes the followers of O'Neill as wearing 'fine linen shirts.' From the time of Charles I. the importance of the trade attracted the attention of the English government; and in 1639 the earl of Strafford, then chief governor, by introducing flax seed and skilled workmen from the Continent, and by the enactment of severe laws for the regulation of the processes employed, endeavoured to promote improvement in the manu-

facture. Though for political purposes successive governments endeavoured by bounties to stimulate the production of linen in Ireland, while they adopted stringent measures to confine the manufacture of woollens to England, but little real or permanent progress was made until the settlement in the north of Ireland of many Protestant families forced to fly from France by the revocation of the Edict of Nantes. Among the refugees were several linen manufacturers, one of whom, Mr. Lewis Crommelin, settled near Lisburn in the county of Antrim with a colony of his own countrymen, who were liberally encouraged by grants from government to devote themselves to the improvement of the linen trade. By Crommelin's efforts and the introduction of improved machinery and processes, both in spinning and bleaching, this branch of industry was greatly promoted, and the Irish weavers enabled to produce linen of much finer quality than had been previously manufactured by them. The next important event in the history of the Irish linen trade was the appointment, by an act passed in the ninth year of the reign of Queen Anne, of a 'Board of Trustees of the Linen and Hempen Manufactures.' Large sums were placed at the disposal of this board, and for several years 20,000*l.* were annually distributed under its management in the encouragement of flax cultivation, and in bounties on the export of linens; while, at the same time, heavy duties were placed on the import of flax fabrics of foreign manufacture. For some years this system tended to advance the Irish trade, but, like all false measures of the kind, prevented its healthy development. It was abolished in 1828, and the exportation of linen, which, while it existed, did not in any year exceed thirty-five millions of yards, in the course of a few years increased to upwards of seventy millions of yards annually. For a considerable time the attempts which were made to introduce the new spinning machinery into Ireland were not attended with much success; and the English and Scotch spinners who, like the Marshalls of Leeds, and Messrs. Ivory, of Glammis, in 1790, had adopted Kindrew's machines, and also various improvements which added to their efficiency, especially what is termed 'wet spinning,' by which the fibres of the flax plant, by being made to pass through warm water in the spinning process, are softened, so that they can be drawn out and made to yield thread of much superior delicacy than when dry spun, were enabled to purchase up the flax offered in the Irish markets, and to produce linens far below the prices of the Irish manufacturers. In 1828 Belfast, which is now the metropolis of the flax industry of the United Kingdom, did not possess a single flax mill; and the credit of introducing the new machinery into Ireland is due to Messrs. Mulholland, of Belfast, and Murland, of Castlewellsan, who in that year laid the foundation of the prosperity of the linen trade of the north of Ireland. Owing to the circumstance that the raw material was produced in abundance on the spot, while in England and Scotland the culture of flax had been almost abandoned, the new machinery enabled the Irish manufacture rapidly to outstrip that of the sister countries, and also of those continental countries which depended upon the ancient system of hand spinning. Though strenuous efforts

have of late years been made both in France and Germany to regain their former position as linen producers, Ireland, especially in the manufacture of certain qualities of flax fabrics, continues to maintain her superiority. France in 1864 had 563,000 spindles, and has at the present time, probably, at least 680,000 at work; Prussia in 1854 had only 47,000, but her twenty-two mills contained in 1864 133,800 spindles, and 38,200 additional spindles had been ordered. The American war, and the diminution in the supply of cotton, tended to stimulate the progress of the linen trade in every part of Europe, and has exercised the most remarkable influence on the development of this branch of industry in the north of Ireland. The successful application of the power-

loom to weaving flax fabrics has also, within the last six or seven years, contributed to promote the rapid extension of the Irish trade. In 1859 there were only 3124 power-looms employed in Ireland, while at present there are 7929. In 1828, as already stated, Belfast did not possess a single spinning mill. Of the 700,000 spindles, and 35,000 workers employed, in the present year in Ireland, three-fourths are to be found located in the neighbourhood of that town.

Next to cotton, coal, and iron, the linen trade is the most important of the United Kingdom. No record is kept of the very large quantity used at home, but the following tables give the imports and exports for the year 1864:—

IMPORTS.

	Quantity.	Value.	Chiefly from
		£	
Linen yarn, ...	2,040,952 lbs.	142,449	France, Russia, and Holland.
Cambrics and French lawns, ...	46,021 yards.	7,477	France.
Damask and diaper, ...	6,903 "	1,036	Hamburg and France.
Sails and sailcloth, ...	387,404 "	19,375	Russia and France.
Other kinds of linen not separately specified, ...	—	112,948	Russia and Belgium.
Total value, ...	—	283,285	

EXPORTS.

	Quantity.	Value.	Chiefly to
		£	
Linen yarn, ...	40,314,568 lbs.	3,000,969	{ Hamburg, Holland, Spain, Gibraltar, Italy, and the United States.
Linen manufactures:—			
Plain and unmixed, ...	171,371,186 yards.	6,005,275	{ Hamburg, Egypt, Cuba, United States, Australia, and West Indies.
" Mixed, ...	12,829,084 "	422,117	{ Egypt, Cuba, United States.
Cambric and lawns, ...	4,993,875 "	186,892	{ United States.
Damask and diaper, ...	1,459,609 "	93,335	{ United States.
Sailcloth, ...	6,941,249 "	394,284	{ Hamburg, United States, and British North America.
Checked, printed, or dyed, unmixed, ...	10,556,315 "	413,365	{ France, Cuba, and United States.
" Mixed, ...	2,137,351 "	85,990	{ Cuba, Mexico.
Ticking, ...	180,083 "	6,244	{ United States.
Lace of thread, ...	12,534 "	326	{ United States.
Sails, ...	—	12,897	{ British North America.
Tarpaulins, tilts, &c., ...	—	15,041	{ Australia.
Hosiery—Stockings of thread, ...	—	22	{ Australia.
" Other sorts, ...	—	25,786	{ South America and Australia.
Tapes and smallwares, ...	—	19,045	{ United States.
Thread for sewing, ...	3,978,321 lbs.	492,194	{ Hamburg and North America.
All other sorts of linen manufactures, ...	—	24,195	{ United States and Turkey.
Total value, ...	—	11,197,977	

The imports and exports of FLAX and HEMP are given in the articles relating to those subjects.

LINES OF INTRENCHMENT are the parapets executed by an army in the field, for its protection, when it is to remain for a time on the defensive. In many cases the protection of an army consists merely of the natural obstacles of the country, as escarpments, rivers, and marshes; but where these are wanting, and occasionally with them, there is formed a continuous breast-work, consisting of redans, as C C, fig. 1, joined by curtains, as a b. The distances of the redans from centre to centre may be 150 yards; such was the construction recommended by Vauban, but since his time it has been modified, by giving to the curtains the form indicated by the

lines a c, b c, in order that the ditch might be more effectually defended from the faces of the redans. These may have the form of equilateral triangles, and the lengths of their sides may be about 50 yards. The entrances are usually in the middle of the curtains.

Instead of simple redans, parts of the line have occasionally been formed of works resembling two united together, as D.

These lines are considered advantageous for the protection of a frontier, to prevent the enemy's marauding parties from making inroads for the purpose of levying contributions or laying waste the country.

When it is intended to defend a bank of a river, or a side of a road, the parapets may consist of a series of branches in the form a b c d, fig. 2. A line

of this kind is said to be à *crémaillères*; and in such situations a succession of fires from the branches, *a b, c d, &c.*, may be directed against the enemy during his advance. The distances between the salient points, *b, d, &c.*, should not exceed 100

enemy being supposed to occupy the ground in front of *a b*, the short branches could be easily raised high enough to defilade those which, as *b c, d e, &c.*, tend towards the foot of the hill.

The most perfect fortification for defending a line of country presenting few natural obstacles to the advance of an enemy, should the importance of the position render it advisable to incur the labour of the construction, would be a series of bastions connected by curtains, either straight or broken. The distance from the centre of one bastion to that of the next may be 180 yards.

Lines of intrenchment composed of works placed at intervals from one another, provided the distances be not so great as to prevent the troops in them from mutually assisting each other, have great advantages over those formed of continuous lines of parapet. In the latter case it is scarcely possible for the army to make a movement for the purpose of attacking the enemy, however favourable the opportunity, since much time would be lost in issuing from the line through the narrow passages. Detached works, on

the other hand, constitute a number of strong points by which the position of the army is secured, while through the spacious intervals an advance or retreat may take place with all necessary facility. It may be added, that detached works are capable of being easily adapted to any kind of ground; for it is merely necessary to place them on the more elevated spots in such situations that the enemy may not be able to penetrate between them without being exposed to their fire. [ENCAMPMENT.]

All the works which have been described consist of parapets formed of earth obtained by cutting a ditch in front.

LINGARD, DR. JOHN, was born at Winchester on the 1st of February, 1771. After receiving the rudiments of education under the parental roof, he was placed, while still very young, in the celebrated Roman Catholic seminary at Douai. Here he displayed great natural acumen, an untiring perseverance, and a passionate love of study; while he necessarily imbibed those religious principles which coloured all his later life, and infused so strong a theological leaven into all his writings. On his return to England he embraced historical pursuits with extraordinary ardour, and, the first among English writers, directed his attention to the stores of information accumulated in the national records and state papers. In 1806 he made his first appearance

yards, and the lengths of the short branches may be about 18 or 20 yards.

It may be added, also, that the line à *crémaillères* (indented line) is convenient when the descent of a hill is in its direction, as from *a* to *e*; for then, the

as an author. He was then in priest's orders at Newcastle-on-Tyne, and he published there his 'Antiquities of the Anglo-Saxon Church,' a work not more replete with erudition than with sophistry and misrepresentation. This was followed by the *magnum opus* which will hand his name down to posterity, 'The History of England from the first Invasion of the Romans to the year 1673.' Though to some extent superseded by the more comprehensive and elaborate research of Froude, Hallam, and Macaulay, it will always enjoy a deserved reputation for its learning, method, and intelligence; for the new paths of historical inquiry which it opened up; and because it provides us with the views of an able Catholic on many controverted points of English history. Where not biased by his religious tenets, his judgments are eminently impartial. His facts are arrayed with care and discrimination, and his style is lucid and dignified. Several editions of the History have been published. Lingard died in 1851.

LINGULA (Lat. *lingua*, 'a tongue'), a genus of bivalvular Mollusca, which abounds in the fossil state.

LINIMENTS (Lat. *linire*, 'to besmear,') are ointments of equal consistency with oil, and therefore rubbed into the skin more readily than ordinary ointments. Chemically, they are of the nature of soap, being a compound of oils and alkalies. Among the most important are, *Liniment of Ammonia*, or harts-horn and oil, being a mixture of solution of ammonia and olive oil, used to relieve neuralgia, rheumatism, and sore throat; *Soap Liniment*, made of soap, camphor, and spirits of rosemary, used for sprains, bruises, rheumatic pains, &c.; *Liniment of Lime*, or Carron Oil, a mixture of equal quantities of olive or linseed oil and lime-water, used for burns and scalds; *Camphor Liniment*, consisting of camphor dissolved in olive oil; and *Simple Liniment*, which is made of four parts of olive oil, and one part of white wax; it is used to soften the skin and to promote the healing of chaps.

LINKOPING. [SWEDEN.]

LINLEY, THOMAS, was born at Wells about the year 1730. He was first the pupil of Chilcot, organist of the abbey, Bath, and finished his studies under Paradies, an eminent Venetian, who had become a resident in this country. Mr. Linley established himself at Bath, where his concerts, supported by the vocal abilities of his two daughters, Eliza and Mary, afterwards Mrs. Sheridan and Mrs. Tickell, were very attractive. He joined with Mr. Stanley, and afterwards with Dr. Arnold, in conducting the London oratorios. In 1775 he set the music to Sheridan's opera 'The Duenna,' which ran seventy-five nights. He next purchased a large share in Drury Lane Theatre in 1775, and in connection with that theatre produced his 'Carnival of Venice;' 'Selima and

Azor,' from the French; 'Love in the East;' and 'The Camp.' He also added those charming accompaniments to the airs in 'The Beggar's Opera,' which are still in use. His Six Elegies, Twelve Ballads, and Madrigal, 'Let me, careless and unthoughtful lying,' were among the most popular of his musical productions. Linley's management of the theatre was generally successful.

Mr. Linley survived his two accomplished daughters and several of his other children. Mr. Linley died in 1795, leaving a widow, a daughter, and two sons, of whom

LINLEY, WILLIAM, born about the year 1771, was the youngest. Having been well educated, and placed in easy circumstances, he devoted most of his attention to the study of music. He produced a considerable number of glees, all of them evincing great originality of thought and refined taste. He composed a set of songs, two sets of canzonets, two comic operas, and many detached pieces; he compiled the 'Dramatic Songs of Shakspeare,' and wrote two novels and several short pieces of poetry. He died in 1835. Thomas Linley, the eldest son, was born at Bath in 1756, and at an early age discovered a remarkable genius for music. In addition to several beautiful pieces contributed to 'The Duenna,' he composed some new music to Shakspeare's 'Tempest,' which show him to have been possessed of a delicate fancy and fertile imagination. He was accidentally drowned in 1778, at the early age of twenty-two.

LINLITHGOWSHIRE, or WEST LOTHIAN, a county of Scotland, is bounded N. by the Frith of Forth, W., S.W., and N.W. by Stirlingshire and Lanarkshire, and S. and S.E. by Edinburghshire, from which it is separated by the rivers Breich and Amond. It lies between 55° 49' and 56° 1' N. lat., and 3° 18' and 3° 51' W. long. Its greatest length is nearly 21 miles, and its greatest breadth somewhat exceeds 10 miles. The area is 81,113 acres, about three-fourths of which are arable. The population in 1861 comprised 19,868 males, and 18,777 females—total, 38,645; being a considerable increase since 1851, when the inhabitants numbered altogether 30,135. At the last census there were 5392 inhabited houses, 166 uninhabited, and 37 building in the county.

The centre of Linlithgowshire consists of a somewhat elevated plateau, surrounded on all sides by hills, of which the highest, in the south-west, attain an elevation of about 1400 feet. Coal is abundant, and several valuable seams are wrought. Limestone and freestone are quarried. The soils are generally strong, well drained, and well manured with lime and farm-yard dung.

The county sends one representative to the House of Commons (the number of registered electors in 1866 being 831), and Linlithgow and Queensferry are each contributory to a parliamentary district.

Bathgate, a market town, is 6 miles S. by W. from Linlithgow. It is a burgh of barony, and governed by a provost, three bailies, and twelve councillors. The town contained in 1861 a population of 4827.

Borrowstownness, commonly written and pronounced Bo'ness, a burgh of barony, is situated on a point of land, or *ness*, which projects into the Frith of Forth, 3 miles N. from Linlithgow. The town is close to the harbour, which is formed by two piers

carried out into the Frith, and is very safe and convenient, with 16 or 17 feet of water at spring tides. The town was very flourishing, and the port had a large commerce till the opening of the Forth and Clyde Canal, and the erection of Grangemouth, in Stirlingshire, into a separate port, since which time it has decreased considerably. The population of the parish in 1861 was 5698, of whom 3814 were in the town. The total number of vessels which entered the port in 1864 was 263 (22,179 tons), and the clearances were 1582 (143,829 tons). The customs revenue in 1865 amounted to only 620*l*.

Linlithgow, the county town, is a royal burgh, and a place of great antiquity. It is 17 miles W. by N. from Edinburgh. The town is situated on the south side of Linlithgow Loch, which is a mile long, and about a quarter of a mile broad in the widest part. The town consists chiefly of one long street, and contains the county buildings and a town-house. It is well supplied with water, and governed by a council of twenty members, including the provost and four bailies. The Edinburgh and Glasgow Railway passes through Linlithgow. It is included in the Falkirk parliamentary district. The population of the burgh in 1861 was 3843; of the entire parish, 5784. The number of parliamentary electors is about 130. The remains of the royal palace of Linlithgow stand on an eminence which projects into the Loch, and divides it into two nearly equal parts. James IV., James V., and James VI. frequently resided in the palace. It was set on fire in 1746, but several of the rooms were preserved from destruction.

Queensferry is a small town and port on the south side of the Frith of Forth, included in the Stirling parliamentary district. The parliamentary burgh consists of part of the parishes of Queensferry and Dalmeny; the royal burgh, of part of Queensferry only. Population in 1861 of parliamentary burgh, 1230; of royal burgh, 760. Parliamentary constituency, 18. It was first chartered in 1636; and is governed by a provost, three bailies, and nine councillors. The harbour is formed by two piers.

LINNÉA, a genus of plants of the order *Caprifoliaceæ*, so called in honour of Linnæus. It is a pretty trailing shrub, and a native of the north of Europe.

LINNÉ, KARL VON, or as his name was Latinized, LINNÆUS, was born at Råshult, in the province of Småland, in Sweden, May 23, 1707. His father was a country clergyman.

In 1727 Linné repaired to the University of Lund in order to study medicine, and was received into the house of Dr. Stobæus, a physician possessing a fine library and a considerable knowledge of natural history. In 1728 he passed the vacation at home, and there formed the resolution of prosecuting his studies at Upsal. To meet the expenses of his academical education, his father was unable to allow him a larger sum than 8*l*. sterling; he consequently suffered much privation, and in vain endeavoured to increase his income by procuring private pupils. His circumstances, however, were somewhat improved by a royal scholarship awarded him on the 16th of December, 1728. He diligently persevered in attendance upon the courses of lectures connected with his future profession—the more diligently perhaps because of his poverty; and by the end of 1729 the clouds of adversity began to disperse. By this time he had

become known to Dr. Olaus Celsius, the professor of divinity at Upsal, who was glad to avail himself of Linné's assistance in the preparation of his 'Hierobotanicon,' a work illustrating the plants mentioned in the Holy Scriptures. His new friend procured him private pupils, and introduced him to the acquaintance of Rudbeck, the professor of botany, then growing old, who appointed him his deputy lecturer, received him into his house as a tutor to his younger children, and gave him free access to a very fine library and collection of drawings.

Here he began to sketch those works which were afterwards published under the titles of 'Bibliotheca Botanica,' 'Classes Plantarum,' 'Critica Botanica,' and 'Genera Plantarum,' and perceived the importance of reducing into brevity and order the unmethodical, barbarous, confused, and prolix writings with which he was surrounded. In the year 1731 Linnæus quitted the house of Rudbeck, and on the 12th of May, 1732, proceeded, under royal authority and at the expense of the University of Upsal, upon a journey into Lapland. The result of this journey was his 'Flora Laponica.' In the beginning of 1735 he set out upon his travels in search of some university where he could obtain the degree of doctor in medicine at the least expense, in order that he might be able to practise physic for a livelihood. He accomplished his purpose at Harderwijk in Holland, June 23, 1735.

In Holland Linné formed a close friendship with Dr. John Burmann, professor of botany at Amsterdam, and it was during his stay with that botanist that he printed his 'Fundamenta Botanica,' a small octavo of thirty-six pages, which is one of the most philosophical of his writings. At this time he was introduced to Mr. Clifffort, a wealthy Dutch banker, who possessed a fine garden and library at a place called Hartecamp. This gentleman engaged the Swede to arrange the objects of natural history contained in his museum, the plants in his garden and herbarium; and assisted him in the publication of a descriptive catalogue, the 'Hortus Clifffortianus.' It was during his engagement at Hartecamp that he visited England, where he seems to have been ill received by Dillenius, at that time professor of botany at Oxford, who was offended at the liberties Linné had taken with some of his genera; but a reconciliation was effected before the Swedish botanist returned to Holland. Towards the end of 1737 he quitted Mr. Clifffort, but did not leave Holland till the following spring.

On his return to Sweden he commenced practice in Stockholm as a physician, and with the aid of a pension of 200 ducats from the government, on condition of lecturing publicly on botany and mineralogy, his prospects for the future became so satisfactory as to enable him to marry at midsummer, 1739. By this time his botanical fame had spread over all Europe, and henceforward his life was one of increasing fame and prosperity. Every branch of natural history he revised or remodelled; books and collections were sent to him from all parts of the world; his pupils, Hasselquist, Osbeck, Sparrman, Thunberg, Kalm, Lofling, and others, communicated to him the result of their travels in Europe, Asia, Africa, and America. He was named professor of medicine at Upsal in 1740, and afterwards of botany; in 1746 he received the rank and title of archiater; in 1757

he was raised to the nobility, and took the title of Von Linné; and by the year 1758 he was able to purchase the estates of Hammarley and Söfja for 80,000 Swedish dollars (above 2330*l.* sterling).

During these eighteen years his life was one of incessant labour; besides his practice as a physician, which was extensive and lucrative, and his duties as professor, he published a most extraordinary number of works on various branches of natural history. In addition to a large number of dissertations bearing the names of his pupils, the 'Flora' and 'Fauna Suecica,' 'Materia Medica,' edition after edition of the 'Systema Naturæ,' and numerous miscellaneous works, some of great importance, he produced his 'Philosophia Botanica,' and 'Species Plantarum.'

Towards the latter part of his life Linné suffered severely in health. He died January 10, 1778, and was buried in the cathedral at Upsal.

After the death of his son, his library and herbarium were purchased for the sum of 1000*l.* by the late Sir James Edward (then Dr.) Smith, and are now in the possession of the Linnæan Society of London.

LINNET, the name of a hard-billed singing bird, which, though well known under one or the other of its various appellations to every English bird-catcher, has, in consequence of the changes of its plumage, and the names applied to it when it appears under those changes, given rise to much confusion in our systems and catalogues, leading both the learned and the unlearned into considerable error.

As synonyms of the Linnet or Common Linnet, we have the Greater Red-headed Linnet, the Greater Redpole, the Rose Linnet, the Gray Linnet, the Brown Linnet; *Fringilla Linota*, Gmel.; *F. Cannabina*, Gmel.; *Linaria rubra major*, Briss.; *Linaria Cannabina*, Swainson, and modern authors. According to Temminck this bird is subject to accidental variation of plumage, from the natural colour even to pure white, or whitish with faint markings; sometimes the plumage is variegated with white, sometimes the general colour is dusky black, the feet being often red. We need not here enter into any long account of the plumage of a bird so well known; yet it may be as well to state that the adult male in spring is thus characterized:—Feathers of the forehead and the breast of a crimson red, terminated by a narrow border of rosy red; throat and front of the neck whitish, with longitudinal brown markings; top of the head, nape and sides of the neck of a pure ash; back, scapulars, and wing-coverts, chestnut brown; under parts whitish; some of the quills blackish, bordered externally with white; tail forked, black. Caged birds do not acquire the roseate tints in spring which adorn the plumage of the free birds. After the breeding season, the roseate tints begin to fade, and gray and brown prevail.

The Linnet is spread over Europe generally, and is abundant in England. It resorts to wild commons, and hedges of furze, building its nest in a low bush; the eggs are bluish white, dotted with purplish red. In winter linnets assemble in flocks, visiting the sea-coasts till spring calls them to return to the uplands, when they separate and pair. Their food consists of small seeds generally, as of the flax, thistle, dandelion, &c., and particularly of those of the cruciform

plants. The song of the Linnet, though short, possesses much sweetness, and hence this bird is very commonly kept in cages.

Besides the Common Linnet, the genus *Linaria* contains two other British species, viz., the Mountain Linnet or Twite (*L. montana*), and the Redpole or Lesser Redpole Linnet (*L. minor*). [FRINGILLIDÆ; GREENFINCH.]

LINSEED, the seed of *Linum usitatissimum*, or Flax plant, contains a mealy albumen of so oleaginous a nature that it yields by pressure in great abundance the oil of linseed. The seed of the flax plant is harvested, not merely with a view to the reproduction of the plant, but also because of the oil which it yields by compression. For both these purposes of sowing and crushing, linseed is largely imported into the United Kingdom. Linseed is also much used as food for small birds. The quantity imported into the United Kingdom in 1865 was 1,350,000 quarters, about two-thirds of which came from Russia, Bombay, and Bengal. It was estimated to be worth 3,690,211*l.*, or about 2*l.* 14*s.* per quarter. In the same year 146,798 quarters, value 390,000*l.*, were exported, five-sixths of the entire quantity having been shipped to Holland and France. The residuum of linseed from which the oil has been expressed is used, under the name of oil-cake, for fattening cattle.

LINSEED OIL may be procured by cold expression of the seeds, a process which makes the oil clearer; or the bruised seeds are roasted in the oil mills, in which case it is brownish yellow, and easily becomes rancid, probably from attracting oxygen. Linseed oil is pellucid, with a faint but peculiar odour and taste. Specific gravity, 0.93. By long boiling it becomes dark brown, tenacious, and thickened, but dries more easily, and in this state is used for printer's ink; by still longer boiling it becomes black, almost solid, and elastically tenacious, like caoutchouc, and in this state it serves for bird-lime.

Linseed oil is used to form liniments, of which the most common is that mixed with lime-water, as an application to burns. But it is much more extensively used in the arts, particularly for painting. The quantity of linseed oil imported into the United Kingdom in 1865 was about 8000 tons, value 340,000*l.*, or about 42*l.* per ton. In the same year about 10,000,000 gallons of British manufacture were exported. The bulk of the former came from Hamburg, Prussia, Holland, and France, and the latter was sent to almost every country in the world.

LIN-TSEH-SU, Chinese Imperial Commissioner, was born at Hing-hwa, in 1785. His father was an artificial flower maker, at which trade the son worked for some years, till a wealthy friend sent him to Peking. He acquired high educational honours, and at the age of thirty was employed by the emperor as censor. He was afterwards appointed to superintend the repairing of the banks of the Yellow River, then to the post of financial commissioner for Kiangnan, and eventually viceroy of the two provinces of Shen-se and Kan-su. On his return, he unwisely urged his sovereign to adopt stringent measures towards the importers, dealers, and consumers of opium, and in dealing with this evil, he excited a war with Great Britain, and brought down upon himself the vengeance of his enraged sovereign. He

was banished, but afterwards recalled, and appointed to a military command. He died January, 1850, while on his way to attack the Taepings.

LINUM, a genus of plants which gives its name to the small family of *Linacæ*. The species are chiefly found in Europe and the north of Africa, but a few likewise in other parts of the world. Few, however, are of any importance, except that which has been an object of culture from the earliest times of which we have any record, that is, *Linum usitatissimum*, or the flax-plant, which is valuable as well for its seed as for the ligneous fibre of its cortical layer, which forms the tow spun into yarn and woven into linen cloth.

The seeds of *Linum usitatissimum* yield several articles useful in medicine and surgery. The testa, or husk of the seeds, is very mucilaginous, the kernel contains much oil, and the farina or meal procured by grinding or bruising the seeds, after the oil has been expressed, furnishes an excellent material for poultices.

LINZ, the capital of Upper Austria, is situated in 48° 19' N. lat., and 14° 17' E. long., on the right bank of the Danube, over which there is a wooden bridge 864 feet long, leading to the suburb Urfahr. The old town consists of one long street, and is of much less extent than the suburbs. There are four gates and three squares. Linz is, on the whole, a well-built city. There are many churches, the largest of which is the cathedral. Other remarkable buildings are—the government house; the hall in which the provincial parliament meets; the town-hall, built in 1414; the city brewery, the custom-house, the gymnasium, the theatre, and the great imperial manufactory of woollen cloths and carpets. Linz gives title to a bishop, and has a lyceum, with a library of 25,000 volumes, several public schools, a deaf and dumb asylum, and many charitable institutions. There are considerable manufactures of cotton and silk goods, leather, gold lace, cards, tobacco, &c. The population of the town at the last census was 27,628. It is a place of considerable trade, with a station on the railway, 100 miles west from Vienna. It is a great railway centre, and its transit trade by the Danube is very considerable. Some Roman antiquities have been discovered here, and it is probably the *Lentium* of the Romans. The fortifications of Linz, constructed on a new plan by Prince Maximilian d'Este, consist of a series of thirty-two detached forts, twenty-three on the right bank and nine on the left bank of the Danube, each at a distance of from one mile to three miles from the town, round which they form a circuit of nine miles, being joined to each other by a covered way. The town and neighbourhood of Linz are celebrated for attractive beauty of scenery. Steamers ply regularly to Vienna, and in summer up the river to Passau and Ratisbon.

LION, *λεων* and *λεαινα*, 'Lion' and 'Lioness' of the Greeks; *Leo*, *Lea*, and *Leena* of the Romans; *Leone* and *Leonessa* of the Italians; *Lion* and *Lionne* of the French; *Löwe* and *Löwin* of the Germans.

The Lion is the largest and most formidable of the existing species of the Cat-tribe [FELIDÆ]. The neck and shoulders of the male are, as a general rule, ornamented with a shaggy mane, and the tail

is tufted at the end. The female has no mane. The colour of the Lion is uniformly tawny, varying in intensity almost to brown; but the young are obscurely striped or brindled. The lion, divided into several varieties, is at the present day confined to Africa, Arabia, India, Persia, and the borders of the Euphrates. Formerly this ferocious animal was common in Egypt and Syria; and not only so, but also in several portions of eastern Europe.

Of the African Lions the following varieties are recorded by Lesson:—

1. *The Lion of Barbary*.—This lion has a deep yellowish brown fur, and the mane of the male is very much developed.

African Lion (Barbary).

2. *The Lion of Senegal*, characterized by fur of a more yellow tint; the mane in the male being less thick, and nearly wanting upon the breast and insides of the legs.

3. *The Cape Lion*, of which there are two races, one yellowish and the other brown; the latter is regarded as the most formidable. The Dutch colonists speak of the *blue* and *black* kinds, and it seems indeed that there is a black-maned lion, one of which, accompanied by his lioness, Mr. Burchell encountered in his travels in Africa.

The lion is not 'king of the forest,' but of wide plains and karroos, interspersed with tracts of brushwood, as well as the borders of rivers. During the day he usually slumbers in his retreat, rousing up from his lair as night sets in, and prowling during the hours of darkness in quest of food. The larger herbivorous animals fall before him, and the horse and the ox of the settler too often become his prey; nor is man always safe from his attack, although experience has taught this fierce brute the deadly nature of fire-arms. Many astonishing details proving the enormous strength of the lion, many thrilling accounts of hair-breadth escapes, and of exciting yet fearful lion-hunts, are on record; but we have not space for such narratives, and therefore refer to the works of various travellers in Africa, as Le Vaillant, Sparrman, Burchell, Steedman, Messrs. Schoon, Gordon Cumming, Livingstone, Baldwin, Andersson, and others.

Of the Asiatic Lions, three varieties appear to be well ascertained:—

1. *The Bengal Lion*.—Mr. Bennett points out the characteristics by which the Asiatic race is distinguished from that of Southern Africa, as consisting principally in the larger size, the more regular and graceful form, the generally darker colour, and the less extensive mane of the African.

2. *The Persian or Arabian Lion*.—This is stated to be distinguishable by the pale Isabella colour of the fur; and those which have been exhibited in England as Persian lions certainly bear out this remark.

3 *The Maneless Lion of Guzerat*.—The ancients (Pliny, viii. 16) evidently were acquainted with a maneless variety of lion in Arabia and Persia, and Olivier enters into details relative to a maneless lion of Arabia and the country around Bagdad. Still nothing very definite was known respecting this variety. In December, 1833, Captain Walter Smee exhibited to a meeting of the Zoological Society of London the skins of a lion and lioness killed by him in Guzerat, and selected from eleven obtained there by him, eight of which he had brought to this country. This lion, he stated, is distinguished from those previously known by the comparative absence of a mane from the sides of the neck and shoulders, the middle line of the back of the neck being alone furnished with longer hairs, which are erect, like those in the same situation in the *Cheetah* (*Felis jubata*). The under surface of the neck has long, loose, silky hairs, and there is a tuft at the angle of the anterior legs. Besides the absence of the extensive mane, the tail is shorter than that of ordinary lions, and is furnished at its tip with a much larger tuft or brush. In this tuft there existed, in the oldest of Captain Smee's lions, subsequently to the arrival of the skins in England, a short horny nail or claw. The ancients believed that the lion lashed himself into fury with his tail, this claw acting as an additional stimulus—an opinion destitute of solid foundation.

The habits of the Asiatic lions do not differ much from those of Africa, excepting that the former, from the state of the country, frequent the jungles. In India the elephant is generally employed in the chase; and in the accounts of most modern sportsmen in Asia, the great courage of the lion is particularly noticed. One of them states that the lions in India, instead of running away when pursued through a jungle, seldom take to cover as a refuge at all, but boldly face their foes, and have been known to bring elephant and rider to the ground. The tiger shrinks from exposing himself.

Reproduction and Length of Life.—The lioness is said to go with young five months, and generally produces two or three at a litter, which are born blind. The age to which the lion naturally lives is doubtful; it is generally supposed to be twenty or twenty-two years. If, however, the assertion is to be relied on, Pompey, the great lion which died in the Tower in 1760, was above seventy years of age, and another from the Gambia is stated to have attained the age of sixty-three. Hybrids have been produced in confinement between the lion and tigress.

There is in America a large feline animal called the *Puma* or *American Lion* (*Felis concolor*). The uniformity of colour in this great cat, combined with its ferocity, were probably the reasons which induced

the early travellers in America, to whom accounts of its destructiveness were detailed, and who perhaps caught hasty glimpses of it, not unaccompanied with terror, to state that there were lions in America, but this was a mistake.

This animal is called, in various languages of America, *Puma*, *Cuguacuara*, *Cuguacurana*, &c.; hence the French *Couguar*. The Anglo-Americans term it *Panther*.

Puma (*Felis concolor*).

Description.—*Adult Male*. No mane. Silvery fawn above, sometimes reddish, the tawny hairs of the upper parts whitish at the tips; nearly white beneath, and on the inside of the limbs; whitish on the throat, chin, and upper lip. Head black and gray irregularly mixed; ears on the outside, and particularly at their base, sides of the muzzle whence the whiskers spring, and end of the tail (which has no tuft), black. Length from nose to tail about four feet; tail rather more than two.

Female coloured like the male. Head small when compared with his.

Young.—Back marked with three chains of spots, which are generally of a blackish brown; dispersed spots or markings on the neck, shoulders, and sides. As the animal advances in age, these markings become more and more obscure, till they are at last lost in the uniform colour.

Geographical Distribution.—North and South America. There is reason to think that it was formerly to be found from Canada to Patagonia, with an extensive range to the east and west, but its geographical area has been very much diminished, and is daily becoming more and more contracted before that civilization which is in our own time obliterating more species than one. Mr Washington Irving ('Astoria') mentions it as being found about the mouth of the Columbia river.

The *Puma* is insidious and ferocious, and when wounded becomes very dangerous to the hunter. It is said to commit wholesale havoc; for when it meets with a herd of animals it will slay in all directions, sucking only a small portion of blood from each victim. To sheep, fifty of which it is said to have been known to kill in one night, it is most destructive, and the squatter well knows the ravages that it will make among his hogs. Though an expert

climber, it is said to haunt in South America the marshy meadow lands bordering on the rivers rather than the forest. In the Pampas it must affect the comparatively open country; for there it is commonly taken by the lasso. In the northern districts the swamps and prairies are its principal haunts; and its prey, where flocks and herds are not, deer principally, upon which it is said to drop in the manner described by Charlevoix with regard to the elk.

The reader must bear in mind that there is another cat of a uniform colour, *Felis unicolor*, Traill, which is said to inhabit the forests of Demerara, and is one half less than the *Puma*. The *Black Cougar*, *Felis discolor*, is allowed by some zoologists, and rejected by others.

LION D'ANGERS. [MAINE-ET-LOIRE.]

LIPARI ISLANDS, the ancient *Æolia*, or *Vulcaniæ Insulæ*, are situated between Calabria and the northern coast of Sicily, and between 38° 20' and 38° 50' N. lat., and 14° 10' and 15° 13' E. long. They are mentioned by the ancient geographers as seven in number. *Stróngyle* (now *Stromboli*); *Lipara*, now *Lipari*; *Hiera*, or *Vulcania*, now *Vulcano*; *Dídyme*, now *Saline*; *Phœnicódes*, now *Felicudi*; *Ericódes*, now *Alicudi*; and lastly *Eúónymos*, supposed to be either *Liscabianca* or *Panaria*. There are several other smaller islands, or rather rocks, such as *Liscanera*, *Basiluzza*, &c., which belong to the same group, but are uninhabited and barren. *Stromboli* consists of a volcanic conical mountain nearly 2500 feet high. It rises abruptly from the sea, except on the N.E., where it has a cultivated space between it and the sea, which produces cotton and some wine, and is inhabited by about 1200 people. The island is about 12 miles in circuit. The flames of the crater are a constant light to the sailors in that sea; but no eruption has taken place for fully 2000 years. It is called by sailors the 'Lighthouse of the Mediterranean.' *Panaria* is an extinct volcano, whose crater slopes on one side to the sea-shore; the bottom or funnel of it is cultivated by a few individuals, who are also fishermen. Population, 200. *Lipari*, the largest and most important island in the group, is a bishop's see, and the residence of a military governor; it is about 18 miles in circumference, and contains about 20,000 inhabitants. It has several mountains with volcanic craters now extinct: it also contains a hot spring, and is wholly composed of volcanic products. The land, which is very fertile, produces cotton, olives, grapes, and the 'Malvasia di Lipari' wine. The town of Lipari with its harbour is on the eastern coast of the island; it contains a castle, several churches, and some remains of antiquity; population (1861), 19,133. Lipari belonged successively to the Greeks, the Carthaginians, and the Romans. *Vulcano* is a barren deserted island, consisting entirely of mountains, the chief of which, Mount *Aria*, contains two craters. *Salina*, 16 miles in circumference, with several villages, and about 4000 inhabitants, consists of two mountains separated by a deep and very fertile valley. *Felicudi*, about 10 miles in circumference, produces corn, fruits, and wine; population, 800. *Alicudi*, the most western of the Lipari group, is hilly and not very productive, has some pastures, and about 1000 inhabitants. The islands belong to Sicily.

LIP'ARIS (Gr. *λαπαρίς*, 'shining'), the Sea-snail,

a genus of fishes of the family *Discobuli*. They resemble the gobies in form, and are generally found under stones at low-water mark.

LIPPE, River. [RHINE.]

LIPPE, a German principality which takes its name from the river Lippe, a feeder of the Rhine, is now divided into *Lippe-Detmold* and *Schaumburg-Lippe*, from the names of the two branches into which the ancient house of Lippe is divided.

Lippe-Detmold forms a compact territory, bounded E. by Hanover, N.E. by Hesse-Cassel, and on the other points by Prussia. The small bailiwick of Lipperode, with the town of Lipstadt, lies detached, being entirely surrounded by Westphalia. The area of the principality is 432 square miles, and the population in 1861 was 108,513. The country is mountainous, but well-wooded. The Weser, the only navigable river, just touches the northern frontier of the principality for a short distance, and receives the Emmer, the Exter, the Werre, the Bega, and some other small streams. The Ems rises in a branch of the Osning or Teutoburgerwald mountains, which run through the territory from S.E. to N.W., and soon enters the province of Westphalia. The Lippe merely touches the bailiwick of Lipperode and the town of Lipstadt. Vast forests of oak, beech, and other timber clothe the higher parts of the mountains, while on the slopes there is the finest arable land. The climate is temperate, but the air is frequently loaded with fogs. The winter is cold and wet; the summer very hot. The chief crops are corn, flax, hemp, potatoes, rape seed, garden vegetables, and timber. The mineral products are plaster of Paris, lime, iron, clay, marble, and freestone; and there is a salt spring from which nearly 40,000 bushels of salt are annually obtained. The breed of horned cattle is good; that of sheep has been much improved of late years. Swine and goats are numerous. The horses are good. The only manufactures of any importance are linen and linen yarn. The present constitution of the state dates from the 15th March, 1853, and nearly all power is in the hands of the prince. The annual expenditure and revenue are about 30,000*l*. The chief towns are Detmold, Lemgo, and Horn.

Detmold, the capital of the principality, situated on the Werra, 47 miles south-west of Hanover, has among its chief buildings a palace, Lutheran and Calvinist churches, and a gymnasium. The inhabitants (with the military) numbered, in 1861, 5598, many of whom are engaged in manufactures of linens and leather, and in several breweries. There are also in the town a normal school, school of arts and sciences, library, Bible society, &c. In the vicinity is the battlefield where the army of Varus was destroyed by the Germans under Hermann (Arminius) A.D. 9. *Lemgo* on the Bega, a walled town with seven gates, has 4000 inhabitants, who manufacture woollen cloth, linen, leather, and tobacco-pipes.

Schaumburg-Lippe, or *Schaunburg-Lippe*, is a principality surrounded by Hanover, the Hessian part of Schaumburg, Lippe-Detmold, and Westphalia. It is 445 square miles in extent, and had a population of 30,774 in 1861. The country is mountainous; its products are similar to those of Lippe-Detmold; but, in addition, it has coal. The chief town and residence of the prince is *Bückeburg*, on

the Aue, which has a population of 4219. Representative institutions of a very limited character were given to Schaumburg-Lippe in 1816. To the prince belongs the whole legislative and executive authority. He acts through a minister, called the President of the Government. The budget, as far as it is known through statements laid at intervals before the Diet, comprises an annual revenue of 34,050*l*., and an expenditure of the like amount. There exists a comparatively large public debt, particulars of which, however, are not published.

The reigning house of Lippe is descended from a count of the same name, who lived in the sixteenth century, acquiring some small territorial possessions in Westphalia. It was only in 1807 that the two counts of Schaumburg-Lippe and Lippe-Detmold were elevated to the rank of princes, and became independent rulers of their estates, by espousing the cause of Napoleon, as members of the Rheinbund. They would have been struck from the list of sovereigns by the Congress of Vienna, but for the protection of Prince Metternich, who preferred having two crowned heads more in Europe to giving their territories to Prussia.

LIPPI, FRA FILIPPO, was born at Florence in 1412. When he was eight years old, he was received into the Carmelite convent Del Carmine. Filippo himself gave early evidence of his extraordinary ability in art by a fresco of the papal confirmation of the rules of the order of the Carmelites; he executed also several other works in various parts of the convent and its church, each work superior to his preceding effort, and so like those of Masaccio that his spirit was said to have passed into Filippo. All these works, however, or at least what remained of them, were destroyed in the conflagration of the church in 1771.

In 1430, or when only seventeen years of age, Filippo repaired by sea to Ancona, was captured by a pirate, carried in chains to Africa, and sold as a slave. Eighteen months after, he amused himself one day with drawing from memory his master's portrait in chalk upon a white wall. The performance so pleased his owner, that he immediately released Filippo, and after he had employed him to execute various pictures, sent him back to Italy. Filippo was landed in Naples, where he remained only a few months, and then returned to Florence. One of the first works which he executed at this time was a small picture of the Adoration of the Madonna, for the wife of Cosmo de' Medici, which is now in the Imperial Gallery at Florence.

Filippo executed many excellent works at Florence, Fiesole, Arezzo, and at Prato. The Death of San Bernardo, painted for the cathedral of Prato, is one of his finest; it is still in the cathedral. Vasari terms the Martyrdom of St. Stephen, in the same church, his master-piece.

Filippo is supposed to have died at Spoleto in 1469, aged 57. He is said to have been poisoned by the relations of Lucrezia Buti, a young Florentine novice who had eloped with him, and by whom he had a son, Filippino Lippi, who was also a celebrated painter. The tale, however, seems without any good foundation.

LIPSIUS, JUSTUS, was born at a village between Brussels and Louvain, the 18th of October,

1547. He was educated at Brussels, Cologne, and Louvain, and at the age of nineteen published 'Varie Lectiones' of some of the principal Roman authors. This work was so highly esteemed that its author was received with distinguished honour at Rome by Cardinal Granvelle and Pope Pius V. After remaining there two years, he was appointed professor of history at Jena, where he resided till 1574. In 1579 he was appointed professor of history at Leyden, and during his residence there professed the Reformed religion; but on quitting Leyden in 1591, returned to the Roman Catholic Church, in which he had been brought up. He was afterwards professor of history at Louvain, where he remained till his death, March 24, 1606. The works of Lipsius, which are very numerous, were collected and published at Antwerp in 1637; and also at Wesel in 1675.

LIQUEUR, the name applied to any alcoholic preparation which is flavoured or perfumed, and sweetened to be more agreeable to the taste. Among the numerous varieties of liqueurs, we may mention the following:—*Aniseed Cordial*, made by flavouring weak spirit with aniseed, coriander, and fennel seed, and sweetening with syrup of refined sugar. *Ab-sinthe* is flavoured with the young tops of certain species of artemisia, and *Clove Cordial*, with bruised cloves, and coloured with burnt sugar. *Curacao* is made from small oranges which have fallen from the tree long before maturity, or from orange-peel, by digesting in sweetened spirits, along with a little cinnamon, and often a little mace or cloves. It is coloured with powdered Brazil wood and burnt sugar. *Maraschino* is distilled from bruised cherries. *Noyau* is a cordial flavoured with bitter almonds, and sometimes with peach or apricot kernels. *Peppermint* is sweetened gin, flavoured with oil of peppermint, which is previously mixed with refined sugar. The imports of liqueurs in 1864 were 170,230 gallons, of which 13,528 gallons were entered for home use.

LIQUIDAMBAR, a genus of plants of the natural order *Altingiaceæ*. The species are only three in number, all forming fine trees, and occurring in Java, the Levant, and North America. *Liquidambar styraciflua* is the species found in Mexico and the United States, in the latter of which it is called Sweet Gum, and forms a large and fine tree. The wood is of a hard texture and fine grain, and makes handsome furniture; but the tree is more noted for the fragrant liquid resin which exudes from incisions in the stem, though not very copiously. This is called *Liquidambar*, or Oil of Liquidambar, which has a pleasant balsamic odour and an aromatic bitter taste. This, becoming dry and opaque, forms what is called Soft or White Liquidambar, which resembles very thick turpentine, has a feeble odour than the liquid balsam, and contains less volatile oil. The word is a contraction of *Liquidum ambar*, or liquid amber, and refers, of course, to this balsamic product.

LIQUIDITY is that condition of a material substance in which the particles have a perfect freedom of motion, without any sensible tendency to approach to or recede from one another, except by the action of some external power. [FLUID, FLUIDITY; FLUIDS, ELASTIC.] When the particles of a substance are situated beyond the limits of the attractive forces existing between them, the repulsive power, arising probably from the action of caloric, causes the

particles to recede continually from one another, and induces the state of aeriform fluidity; and when the particles of a substance are, from any cause, brought so near one another that the attraction of affinity is in equilibrio with the repulsive force of the caloric, the particles become freely movable in any direction about one another, whatever be their form; and thus may arise the condition of liquidity.

The particles of a liquid are held together with considerable force, notwithstanding their freedom of motion, since a small quantity of a liquid has a tendency to take a spherical form when at a distance from any substance for which its particles have greater affinity than for one another: this is very evident in mercury, oil, and water, the first of which, on being suffered to fall on a table, immediately divides itself into globules, and the others take a like form when a small quantity of either is suspended from a pointed extremity of any object.

The expansions of any liquid, at different temperatures, for equal increments of caloric, are not equal to one another.

From the experiments of MM. Dulong and Petit, the mean expansion of mercury, in volume, for 1° (Fahr.) between the temperatures of freezing and boiling water, is expressed by '000101; between the freezing-point of water and 392° (Fahr.) by '000102; and between the freezing-point of water and the temperature at which mercury boils, by '000105. The expansion, in volume, of water for 1° (Fahr.) between the temperatures of 34° and 44° is '00002; at 90° it is '0002; and at 212°, '00088. The expansion of spirit of wine, highly rectified, for 1° is, at 0°, '00047, and at 172°, '00083.

LIQUORICE. [GLYCRRHIZA.]

LIRIODENDRON. [TULIP-TREE.]

LIRIS. [CAMPANIA.]

LISBON (Portuguese, *Lisboa*; French, *Lisbonne*; German, *Lissabon*), the capital of the kingdom of Portugal, is situated on the northern bank of the Tagus, about 9 miles above the bar or entrance of the river, in 38° 42' N. lat., and 9° 8' W. long. It rises in the form of an amphitheatre from the bank of the river, being built on a succession of hills, the highest of which are the hill of Buenos Ayres, or Estrella, to the west, and the Castle Hill to the east. Most of the streets are steep, irregular, and tortuous, besides being ill paved and dirty. The new town, built in a valley between the hills, after the earthquake of 1755, contains, however, many fine streets. At the river's edge is a fine square called Praça de Commercio, one side of which is formed by the Tagus, and the other sides by the arsenal, the custom-house, the exchange, royal library, and other public buildings. Other open places are the Praça da Figueira, or market-place, the Praça do Rocio, and the Passeio Publico, or promenade. The oldest part of Lisbon, east of the castle, consists of narrow streets of lofty houses. Westward of the new streets the town ascends a slope, crowned by massive buildings, chiefly convents and churches, which crown the summits of the hills, and tower above all the rest. The extreme limits of Lisbon extend about four miles by one and a half; but many parts of the included area (3000 square acres) are occupied by extensive gardens, plantations, the naked steep

declivities of the hills, and by ruins and waste ground. West of the bridge of Alcantara a line of streets parallel to the Tagus connects Lisbon with the market-town and royal residence of Belem, or Bethlehem.

The Tagus from Belem up to Lisbon is little more than 1 mile in width, but opposite the city it expands to 5 miles, and assumes the noble aspect of a fine estuary. The southern bank is studded with a number of small towns and villages, which supply the capital with provisions. The river affords to Lisbon a most splendid and safe harbour, which might contain all the fleets of Europe. The largest men of war can anchor close to the city. The entrance of the river is defended by two forts with lighthouses adjacent, St. Julian on the north bank, and Bugio on a small island opposite, which is joined to the southern bank at low water.

The most striking and imposing buildings of Lisbon are its vast and massive convents, which crown the hills, and look like palaces and fortresses; the royal palace of Ajuda; the theatre of San Carlos, or opera-house; and the cathedral, and other large churches, especially those of Do Caraço da Jesus, Santa Engracia, and the Martyrs.

The climate of Lisbon is healthy and genial; it is very hot and dry in the summer months, when the heat is often 96° of Fahrenheit, but is relieved by north-west winds: heavy rains fall in November and December; cold clear weather prevails in January, but in February the weather becomes mild again, and the spring begins. Snow is a very rare occurrence.

A fine aqueduct, Os Arcos das Agoas Livres, supplies Lisbon with good water, brought from several springs in the neighbourhood, through tunnels and along viaducts, to a central reservoir, from which the water is distributed to several fountains about the town. The Gallegos, or porters, draw water in small barrels from the fountains, and sell it from house to house, or cry it about the streets. Lisbon is ill provided with conduits or sewers, and all the filth is thrown into the streets, from which it is washed off by the rain into the river.

Olive and orange trees, cypresses and judas trees, and some elms and poplars, grow near the city. Much of the adjacent country is covered with large gardens called 'quintas,' surrounded by high walls, which bound the view on every side. A large house is usually attached to them, in which the families of the owners spend part of the summer.

The population of Lisbon at the last census was 275,000. Its trade, though much diminished since the loss of Brazil, is still considerable. It exports wine, fruits, and oil; and it imports corn, salt fish, salt butter, cheese, timber, iron, lead, tin, copper, coals, tar, and all sorts of foreign manufactures, with which it supplies the whole southern part of the kingdom. Lisbon has some manufactories of silks, paper, soap, and leather; its goldsmiths and jewellers are very expert; and there are also sugar refineries and potteries. Lisbon is 764 miles by the shortest sea-route from Plymouth, steamers making the voyage in about three or four days.

LISBURN. [ANTRIM.]

LISCOW, CHRISTIAN LUDWIG, born at Wittenberg, 1701, ranks high in Germany for his satirical writings. About the year 1739 he was private tutor

at Lübeck. After this he became private secretary to the Geheimrath von Blöme, and subsequently entered the service of Von Heinecker at Dresden. Having offended the English minister at that court, he drew upon himself the resentment of Count Brühl, who caused him to be sent as a state prisoner to Eilenburg, where he died shortly afterwards, October 30, 1760. Some, however, have questioned the truth of his having been in confinement. The first complete edition of Liscow's works was published by Mühler, in 3 vols. 8vo, Berlin, 1806.

LISIEUX. [CALVADOS.]

LISKEARD. [CORNWALL.]

LISLE, or L'ISLE. [VAUCLUSE.]

LISMORE. [WATERFORD.]

LISSA. [POSEN.]

LIST, DR. FREDERIC, an eminent political economist, and member of the Wirtemberg Parliament, was born in 1789. His general opinions were of so bold and liberalizing a tendency, that he was at length expelled the Assembly; but in 1819 he established a journal, and published several spirited works on political economy, in support of his peculiar views and opinions. He at length succeeded in laying the foundation of the celebrated Zollverein (the Customs Union of the German States), which, after encountering various obstacles, was eventually adopted by nearly the whole of Germany; but the doctor, having been long exposed to serious annoyances and disappointments, lost his mental faculties, and in a fit of insanity committed suicide in 1846.

LISTER, THOMAS HENRY, a historian and novelist, was born in 1801, and may be said to have descended from a literary ancestry; for both his father and grandfather, of whom Miss Seward has left some favourable notices, were well known in the republic of letters. Among Lister's lighter productions may be mentioned his 'Granby' and 'Herbert Lacy,' two 'fashionable' novels of considerable merit. But his 'Life and Administration of Lord Clarendon,' and his tragedy of 'Epicharis,' have contributed to establish his reputation as a historian and dramatist. He died in 1842.

LISTON, JOHN, a very clever and popular actor of farce and low comedy, was born in 1776 in the parish of St. Anne's, Soho, and in early life was engaged as a day-school teacher. But directing his attention to the stage, in 1805 he obtained an engagement at the Haymarket Theatre, where his peculiar drolleries and natural humour drew vast crowds of laughter-loving playgoers, and established his fame as a first-rate comedian. His acting, in the very clever comedy of 'Paul Pry,' which was one of his favourite characters, acquired him immense popularity, and has probably never been surpassed. On quitting the Haymarket he made his appearance on the boards of Covent Garden, where he remained, increasing in popularity, till 1823, when he received an engagement at Drury Lane, where he acted for some time. But in 1831 Madame Vestris, the then manager of the Olympic Theatre, offered him the enormous salary of 100*l.* per week, which he was induced to accept, and played on the boards of that theatre for six successive seasons. This may be said to have closed his theatrical life; but he was able to retire with a very comfortable independence. He died in 1846.

LISTOWEL. [KERRY.]

LITANY. A collection of prayers and supplications. The term is derived from the Greek *λειτουργία*, and was adopted by Christian writers at a very early period.

In the Common Prayer Book of 1549 (the first book of King Edward), the Litany was placed between the Communion Office and the Office for Baptism, under the title of 'The Letany and Suffrages;' which book also directed it to be said or sung on Wednesdays and Fridays. In the review of the Common Prayer in 1552, the Litany was placed where it now stands, with the direction that it shall be used on Sundays, Wednesdays, and Fridays, and at other times when it shall be commanded by the ordinary. Till the last review, in 1661, the Litany was used as a distinct service, and followed the morning prayer; it was then directed and has ever since continued to be read as one office with the Morning Prayer, after the third Collect for Grace. In the Roman Catholic Church three litanies are used: 'the Litany of the Saints' (which is the most ancient, and the only one in the public service books of the church), 'the Litany of the Name of Jesus,' and the 'Litany of our Lady of Loretto.' Throughout all the varieties of form which the litanies used publicly in different churches have assumed, one characteristic has always been maintained, viz., that the prayer should alternate between the priest and the people. The former announces the object of each petition, and the latter reply in a common supplicatory form.

LITCHI, or **LEE-CHEE**, the produce of the *Nephelium litchi*, natural order *Lapindaceæ*, a native of China. The fruit is about the size of a small walnut, of a red or green colour, with a thin tough rind, and a colourless pulp, in the centre of which is one dark brown seed. The pulp is rather sweet, and very pleasing to the palate. The Chinese dry the fruit, and much of it has been sent to England during the last few years.

LITHARGE. [LEAD.]

LITHIC ACID. [URIC ACID.]

LITHIUM, a metal, the oxide of which is one of the earths, and is called *lithia*: it occurs in a few minerals, combined with silica. When separated, the metal resembles sodium in whiteness; but it has not been much examined.

Oxygen and *Lithium* combine with great readiness, and are separable with difficulty. The compound is *lithia*, which as a hydrate exhibits a crystalline structure; the oxide is supposed to consist of $L^1 O^1$. *Chlorine* and *Lithium* ($Ch^1 L^1$) form a white semi-transparent substance, very deliquescent, and soluble both in water and in alcohol. By evaporation cubic crystals are obtained. *Sulphur* and *Lithium*, when obtained in combination by decomposing the sulphate of lithia with excess of charcoal, form an extremely pyrophoric substance. *Fluorine* and *Lithium* form a fusible compound, prepared by dissolving lithia in hydrofluoric acid; it is difficultly soluble in water; the solution deposits small opaque crystals.

Nitrate of Lithia ($L^1 Acid^1$) is obtained by adding lithia to the acid. This salt is very deliquescent; when the solution is gently evaporated, crystals are obtained. Its taste is like that of nitre; it is extremely fusible, and becomes by heat as liquid as water. *Carbonate of Lithia* ($L^1 Acid^1$) is very slightly soluble in cold water; it is decomposed by acids with effervescence, and has an alkaline taste.

Sulphate of Lithia ($L^1 Acid^1$) is very soluble in water; it has a saline taste without bitterness, and crystallizes only in irregular masses. *Phosphate of Lithia* is an insoluble compound.

Characters of Lithia and its Salts.—Lithia acts so readily upon platinum, that this property will serve to detect a small quantity in any substance. Lithia is distinguished from soda and potash by its greater saturating power; chloride of lithium is distinguishable from the chlorides of sodium and potassium by its solubility in alcohol, and the solution burns with a red flame. Unlike potash and soda, lithia forms a difficultly soluble carbonate and phosphate.

LITHOGRAPHY, (Gr. *λίθος*, 'a stone,' and *γραφειν*, 'a graving' or 'writing') the art of printing from stone, was invented by Aloys Senefelder, at Munich, about the end of the eighteenth century. It consists in writing or drawing on stone with a pen, brush, graver, crayon, or chalk; or in transferring to the stone an impression printed upon transfer-paper with transfer-ink from an engraved copper or steel plate, or a writing or drawing made with the pen or brush on transfer-paper; and then printing as described below.

The best *lithographic stones* are found at Kelheim and Solenhofen, near Pappenheim, in Bavaria; they have been found also in Silesia, England, Ireland, France, Canada, and the West Indies. These stones are composed of lime, clay, and silicious earth, and are of various hues, from pale yellowish-white to a light buff, reddish, pearl-gray, light-gray, blue, and greenish colour. Those of uniform colour are the best. The yellow-buff ones, being soft, are adapted for lettering and transfer; the pearl-gray ones, being harder, for chalk-drawings and engraving. They are found in beds, commencing with layers of the thickness of paper, till they reach the dimensions of one, and several inches in thickness, when they are easily cut, being yet soft in the quarries, to the sizes required for printing purposes. The stones are ground plane with sand, and when required for the pen, the brush, the graver, or transfer, they are polished with pumice stone. Imports in 1864, 13,000 cwts.

The two chief agents employed in producing designs, writings, &c., on stone, are termed lithographic chalk, and lithographic ink. The lithographic ink is composed of 2 parts of white wax, 2 shell-lac, 1 hard soap, $\frac{1}{2}$ tallow, $\frac{1}{4}$ carbonate of soda, and 1 of powdered lamp, or better, Paris black. The lithographic chalk (crayon) is made of 3 parts of white wax, 2 hard soap, 1 shell-lac, $\frac{1}{2}$ 'drops of' mastic, 1 tallow, $\frac{1}{2}$ old lard, $\frac{1}{2}$ Venetian turpentine, $\frac{1}{4}$ Brunswick black, $\frac{1}{4}$ carbonate of soda, and $1\frac{1}{2}$ of Paris black, properly melted and burned together. The mass is then poured into a mould, from which it takes the form required to fit it for use. The chalk is used dry, as it comes from the mould; but the ink, rendered soluble by the presence of the soap, is dissolved by attrition in water, and used with a pen or a pencil of camel hair.

To render the lithographic process intelligible, let it be supposed that the artist now completes a drawing with the chemical chalk just described, upon a grained stone. If, while in this state, a sponge filled with water were passed over the face of the stone, the

drawing would wash out, the chalk with which it is made being, as we have seen, soluble in water, by reason of the soap which it contains. Before, therefore, it is capable of yielding impressions, a weak solution of nitrous acid is poured over it, which unites with and neutralizes the alkali or soap contained in the chalk, and renders it insoluble in water. After this, the usual course is to float a solution of gum over the whole face of the stone; and when this is removed, if a sponge and water be applied to its surface, as before supposed, the drawing is found to be no longer removable, because the chalk with which it is executed is now no longer soluble in water. In this state the work is ready for the printer, who obtains impressions by the following process.

Having thrown a few drops of water on the stone, and spread them with a sponge, so as to wet, or rather damp, the whole surface equally, the printer finds that the water has been imbibed by the stone only on those parts not occupied by the drawing, which, being greasy, repels the water and remains dry. A roller properly covered with printing-ink is now passed over the whole stone, which will not even be soiled where it is wet, from the antipathy of oil and water. But the parts occupied by the drawing being, as we have seen, dry and greasy, have an affinity for the printing-ink, which therefore passes from the roller, and attaches itself to the drawing. In this state it is said to be charged, or rolled in. Damped paper is then put over it, and the whole being passed through a press, the printing-ink is transferred from the stone to the paper, and this constitutes the impression. By repeating in this manner the operations of damping the stone and rolling in the drawing, from 1000 to 1500 good impressions may be obtained. A steam lithographic press by Huguet of Paris has recently been introduced, by which from 3000 to 4000 impressions have been obtained from one stone. [See Plates PRINTING, 'Lithographic Press.']

The modes of lithography are, as we have said, various, but the illustration just given will explain the principle of them all. It consists in the mutual antipathy of oil and water, and the affinity which the stone has for both, *i.e.*, in its power of imbibing either with equal avidity.

To insure complete success, great nicety is requisite in the preparation of all the agents employed in this art. Those who wish to study or practise the art in its full extent will do well to consult 'A Complete Course of Lithography,' by its discoverer, M. Senefelder, or 'A Manual of Lithography,' by M. Raucourt, both translated into English.

Plates of zinc have, for some descriptions of common work, been much used as substitutes for the German stones; the practice is then called *zincography*, but excepting the difference of the material on which the work is performed, it is precisely the same art as lithography.

LITHOLOGY, in mineralogy, is the name given to the study of the mineral structure and constituents of rocks. By some it is used in a wider sense, and is regarded as including the relations of different rocks to each other. It is, however, better to limit its use to such features of rocks as can only be known by the aid and appliances of inorganic chemistry.

LITHOMARGE, a mineral of a white, gray, or blue colour, occurring in massive or scaly glimmering

particles; the constituents of which are silica, alumina, oxide of iron, chloride of sodium, and water.

LITHONTRIPTICS (λίθος, 'a stone,' and τριβω, 'to rub or bruise'), medicines or other means which are thought to possess the power of dissolving stone or calculus in the urinary organs. With few exceptions, their employment has been nearly empirical; and aggravation of the case has as frequently resulted as benefit from their employment. The researches of recent chemists and pathologists have given something approaching to a scientific explanation of the circumstances under which calculi form, as well as of their varied characters, so that more good may reasonably be expected from the use of lithontriptics than has hitherto been realized. [CALCULUS.]

LITHOPHA'GIDÆ, a name applicable to all marine *Conchifera*, *Mollusca*, *Radiata*, &c., that penetrate stone, masses of madrepore, and other hard corals, forming therein a nidus for themselves; but more particularly applied to the *Conchifera*. The perforation is effected by chemical erosion and mechanical action. The erosion is not confined to the *Conchifera* only; for *Patella* has the power of perforating certain rocks to a limited extent: nor to the *Mollusca* generally; for some of the *Echinidæ* (*Radiata*), for instance, are known to make shallow basin-like lodgments in the rocks whereon they dwell.

LITHOSPERMUM, a genus of plants belonging to the natural order *Boraginæ*. The whole of the species are noted for the stony hardness of their pericarps or nuts.

The nuts of *L. officinale* were formerly esteemed as an infallible lithontriptic. Their virtues in this respect are, however, entirely imaginary. This species is indigenous to Europe, Asia, and North America. It is found in dry and stony places in Great Britain, but sparingly. *L. purpureo-cæruleum* has white, highly polished, and hispid nuts. It is a native of middle and south Europe, of the Caucasus in woody mountain places, and of England and Wales in chalky soil. *L. arvense*, Bastard Alkanet, has white and small flowers, the root of a bright red, communicating its colour to paper. It is a native of Europe, Asia, Africa, and some parts of North America, and is found plentifully in the corn-fields of Great Britain.

LITHOTOMY (from λίθος, 'a stone,' and τέμνω, 'to cut'). Although urinary calculi may be extracted from the kidneys, urethra, or bladder, the term lithotomy is restricted to the operation of cutting into this latter viscus for the purpose of removing one or more stones. Before the operation is performed, it is necessary to determine with certainty the presence of a stone, which is done by *sounding* the patient. This consists in introducing into the bladder, through the urethra, a metallic instrument called a sound, by means of which the stone can be plainly felt, and an audible noise perceived on striking it: till this be rendered evident, no surgeon would be justified in undertaking the operation.

Several modes of performing lithotomy have been in use; but that which is mostly had recourse to at the present day is the *Lateral Operation*—so called from the prostrate gland and neck of the bladder being cut laterally, in order to avoid wounding the rectum. The patient having been put under the influence of chloroform, and then sounded, to ascertain that the stone is actually within the bladder (for instances have

occurred of stone becoming encysted a short period before the operation), he is placed on his back upon a table, with his buttocks projecting rather beyond its edge; he is then made to grasp the outside of each foot with the hand of the same side, and the two pair are firmly bound together. A *staff*, which is an instrument shaped very much like a catheter, or sound, but somewhat longer, and grooved on its convex side, is passed through the urethra into the bladder, where it must be retained firmly by an assistant; its convexity looking towards the perineum, and the groove slightly inclined to the left side of the patient. The operator now commences his incision below the bulb of the urethra, about an inch and a quarter in front of the anus, and continues it obliquely downwards to the left of the raphe of the perineum for three inches, till it reaches midway between the tuberosity of the ischium and the anus: this should cut through the integuments and superficial fascia. The next incision, made in the same direction, divides the transversus perinei muscle, and exposes the membranous portion of the urethra, and the groove in the staff must be felt for with the finger; into this groove, which serves as a director for making the concluding section of the operation, is inserted the point of the knife, which is then pushed along the groove in the staff till it enters the bladder. The surgeon then introduces his left forefinger to ascertain that the wound is sufficiently extensive to permit the extraction of the stone; and if it be not, he either repeats the last incision, or dilates the opening in the bladder with his finger. The staff is now to be withdrawn, and the forceps carefully introduced, and the stone seized and removed.

Dr. A. Buchanan of Glasgow has contrived another form of staff, called the rectangular, which necessitates only *one* incision; the operator at once entering the groove in the staff, and, without removing the knife, pushing it into the bladder by a straight thrust. This operation is very easily performed, and has been attended with very great success. The writer has performed it nineteen times with only *one* fatal result.

LITHOTRITY (from λίθος, 'a stone,' and the root τρι-, 'to pierce'); *Lithotripsy* (from λίθος, and τριβω, 'to break'), the reduction of a calculus in the bladder into small pieces, by means of instruments passed into that organ through the urethra, so that the fragments may be discharged through the latter tube. This operation must be ranked among the most brilliant achievements of modern surgery, as it proposes to substitute a nearly perfectly safe proceeding for the more serious and dangerous operation of lithotomy. It, however, can only be performed with certainty of success in the adult, and on calculi of a comparatively small size. The lithotrite is an instrument consisting of a smooth hollow steel rod 15 inches in length, with its extremity about 1½ inches bent at nearly a right angle. Through this rod glides another, its extremity bent the same as the first, in such a manner that its bent end is received into a groove in the bent end of the first. When shut up, the two rods seem one instrument, but when introduced into the bladder the inner one can be withdrawn so as to leave an interval between the bent ends, into which the stone falls or is caught, and by a rack and pinion the bent ends are driven together,

and the stone crushed to pieces. Great care is necessary in the employment of instruments in such a delicate organ as the bladder.

LITHUANIA, a large tract of country in the north of Europe, which now forms the Russian provinces of VILNA, GRODNO, BIALYSTOCK, MINSK, MOHILEV, and VITEPSK, with the palatinate of Augustov, in the kingdom of Poland.

LITOPA, a genus of pectinibranchiate molluscs, established by M. Rang, and placed by him between *Janthina* and *Phasianella*. M. Bellanger, we believe, was the first to discover the singular fact that this mollusc, which lives upon floating plants in the sea, sometimes quits them, holding itself secure by a thread. Subsequently M. Rang detected some small glairy masses which appeared to be attached to the foot, and which were easily drawn out to a considerable length.

LITMUS, or LACMUS, a fine blue but fugitive colour prepared from the *Leconora tartarea*, a lichen which grows in the Canary and Cape Verde islands. In order to extract the colouring matter, the lichen is cleaned and reduced to powder; this is then mixed with urine and lime, and in a few days the blue colour is developed. The litmus is imported in small cubical cakes of dusky blue colour, which are light and easily reducible to powder.

Litmus is used as a chemical test for detecting the presence of acids, by which it is turned red, and the blue is restored by alkalies, so that when slightly reddened it may also be employed to detect alkalies. It will exhibit the presence of sulphuric acid, even when diluted with 100,000 times its weight of water.

LITTLETON, THOMAS, was the eldest son of Thomas Westcote, of the county of Devon. Educated at one of the universities, he removed to the Inner Temple, where in due time he became one of the readers. On the 26th April, 1466, he was appointed one of the judges of the Court of Common Pleas, and went the Northamptonshire Circuit. He married Joan, widow of Sir Philip Chetwin, of Ingestre, in the county of Stafford, one of the daughters and co-heiresses of William Burly, Esq., of Broomscroft Castle, in the county of Salop, with whom he had large possessions. By her he had three sons and two daughters.

Littleton died at Frankley on the 23rd August, 1481, aged about sixty, and was buried in Worcester Cathedral.

Littleton's work on English Tenures is written in Norman French, divided into three books, and addressed to his son. The style of this treatise is very good. It combines the qualities of clearness, plainness, and brevity, in a degree that is extraordinary for the rude age in which the author wrote.

Littleton very seldom quotes any authority. Owing to the alterations in and additions to the law since Littleton wrote, there is much of Littleton's book that is not now law; but Littleton is still an indispensable manual to the student of jurisprudence. Roger North observes in his 'Life of the Lord-Keeper Guildford,' 'Coke's Comment upon Littleton ought not to be read by students, to whom it is at least unprofitable; for it is but a commonplace (book), and much more obscure than the bare text without it. And, to say truth, that text needs it not; for it is so plain of itself, that a comment, properly so called,

doth but obscure it.' It is much better for the student who wishes to lay well the foundations of his professional knowledge to read Littleton first without the comments of Coke, which he will find useful afterwards, when he wishes to examine any particular point very minutely.

LITRE, the French standard measure of capacity in the metrical system. It is a cubic décimètre, or a cube whose sides are each 3·9371 English inches. It contains a little less than our quart; more precisely, it is 22009637 of a gallon. The litre is subdivided into the decilitre, centilitre, and millilitre, or the tenth, hundredth, and thousandth part of a litre. Ten litres make a decalitre; 100 a hectolitre; 1000 a kilolitre. The hectolitre is equal to 3439009 English quarter, or nearly $2\frac{3}{4}$ bushels, and is the common measure for grain.

LITUITES (Lat. *lituus*, 'a curved trumpet'), a group of fossil Cephalopods, found in the Silurian and other systems. The shell is partly convoluted and partly straight.

Lituites Cornu-arietis.

Mr. Dallas calls these Lituities the representatives of the Nautilus and cuttle-fish, which, though not so plentiful as in former times, are still very common in certain localities.

LITURGY (from the Greek *λειτουργία*, which originally signified at Athens, 'certain public functions or duties to which the citizens were personally liable') is a form of public devotion, and more particularly the Office of Common Prayer used in our own or any other church. In the Greek or Constantinopolitan church three Liturgies are in use: those of Basil, Chrysostom, and the Liturgy of the Præsanctified. In the Romish church the Liturgy is divided into several books or offices, as the breviary, the ceremoniale, or office peculiar to the pope; the missal, or office of the mass; the pontificale, directing the functions of the bishops; and the rituale, or pastorale, for the guidance of the simple priests.

At the Reformation all the Protestant churches on the Continent, without a single exception, introduced liturgies for the decorous celebration of divine service.

Previous to the Reformation of the Church of England the service was performed in Latin, and different liturgies were used in different parts of the kingdom. The cathedrals of York, Lincoln, Hereford, and Bangor, and even Aberdeen in Scotland, had their respective uses; but no cathedral had such a variety of service books for its use as Sarum.

The publication of King Henry VIII.'s 'Primer'

in 1535, in the vernacular tongue, was one of the first steps in the reformation of doctrine and worship in the Church of England. In 1547, 1st Edward VI., Archbishop Cranmer, Bishop Ridley, with eleven other bishops and eminent divines, were commissioned by the king in council to compile a liturgy in the English language, which was confirmed by Parliament in 1548, and published in 1549. It 1551 it was slightly revised and again confirmed by Parliament. Both acts were repealed in the first year of the reign of Queen Mary; but upon the accession of Elizabeth, several learned divines, headed by Archbishop Parker, were appointed to make another review of King Edward's liturgies, when the restoration of the second book of King Edward VI. was determined upon, and finally confirmed by Parliament. The Act received the royal assent April 29, 1559. In the 1st of James I., after the conference at Hampton Court, a few slight alterations were introduced. In this state it continued till the time of Charles II., who, in 1661, issued a commission to empower twelve bishops and as many Presbyterian divines to consider the objections raised against the liturgy, and to make such reasonable and necessary alterations as they should jointly agree upon, nine assistants on each side being added to supply the place of any of the twelve principals who should happen to be absent. The conference broke up without anything being done, except that some particular alterations were proposed by the episcopal divines, which in the May following were considered and agreed to by the whole clergy in convocation. The liturgy was then brought to its present condition, and was unanimously subscribed by both houses of convocation of both provinces on Friday, 20th of December, 1661, and being brought before Parliament the March following, both houses passed an Act for its establishment; and the earl of Clarendon, then lord-chancellor, was ordered to return the thanks of the lords to the bishops and clergy for the great care and industry shown in its revision. Of late years several attempts have been made by Lord Ebury and others to obtain a revision of the liturgy, the objections being that it is too long, and contains too many repetitions for one service, and that particular parts require modification or alteration. Hitherto the heads of the church generally have objected to any change, and the attempts at alteration have therefore been unsuccessful.

LIUTPRANDUS, or LUITPRANDUS, was a deacon at Pavia in the year 946, when Berengarius, marquis of Ivrea and regent of the kingdom of Italy, sent him as his ambassador to Constantinople, where he learnt the Greek language. After his return he was made bishop of Cremona, where he died. He was a man of considerable learning for his age, and his works are valuable for the historical information which they contain.

LIVER. The liver is the secreting organ or gland by which the bile is formed. Its existence has been traced very low in the scale of animals; and parts supposed to have an analogous function have been found in insects, but their nature is at present a disputed question. The differences in regard to size, form, and colour, which the liver presents in the higher animals (mammalia, birds, reptiles, amphibia, and fishes), are of no great importance.

In man the liver is a large solid viscus, of a reddish

brown, or mottled red and yellow, colour, situated immediately beneath the diaphragm, in the right hypochondriac, and partly in the epigastric region of the abdomen. [ABDOMEN.] When enlarged, it can be felt by the hand applied below the ribs on the right side. It is flattened in the vertical direction, is thinner at its anterior than at its posterior border; and its outline, when viewed from above, is irregularly ovoid. The upper surface, which is convex, is applied to the diaphragm; the lower, which is irregularly concave, lies above, and in contact with the stomach, large intestine, and right kidney, has attached to it the gall-bladder, and presents two deep furrows, which divide it into several compartments, termed by anatomists lobes. Of the furrows, one running from before backwards (the longitudinal fissure), transmitted, during uterine life, the vessel which conveyed the blood from the placenta to the heart of the fetus; it afterwards contains merely the cord-like remains of that vessel, now impervious in the greater part of its extent. The second furrow, in the under surface of the liver, is called the transverse fissure, since it crosses the former at right angles, lying, however, chiefly to its right side; it serves to allow the entrance of bloodvessels and nerves to the liver, and the exit of the bile-ducts. Like other viscera of the abdomen, the liver receives an investment from the lining membrane of that cavity, the peritoneum, which, being reflected from it at different points, forms broad bands connecting the liver with surrounding parts.

The intimate structure of the liver consists of ramifications of the hepatic artery and vein, the portal vein, and the hepatic ducts. The ultimate arrangement of these different bloodvessels in the liver is very peculiar. When the substance of the liver is torn, it is seen to be composed of innumerable granules of about the size of a pin's head; each of these contains the elements of a liver. They are connected most intimately with the branches of the hepatic vein, a small twig of which is contained in the interior of each, while on their exterior surface and in their interstices run branches of the portal vein, hepatic artery, and bile-duct. The mass of each granule or lobule is constituted in great part of a close network of capillary bloodvessels, which communicate on the exterior with the small branches of the portal, and on the interior with the twig of the hepatic vein. The blood brought by the portal vein, therefore, is poured into the capillary net-work of each granule or lobule of the liver, and, after yielding in it the constituents of the bile, is received into the branches of the hepatic vein, whence it is transmitted to the general vascular system. The branches of the hepatic artery soon become very minute on the exterior of the lobules, and few can be traced into their interior; it is probable that, after having nourished the coats of the vessels and ducts, and other tissues of the liver, the blood of the hepatic artery is poured into the minute net-work formed by the ultimate division of the portal vein, and contributes, with the blood of that vein, to yield the constituents of the bile.

The biliary canals, reduced in number by successive reunion to two tubes, one from the right, the other from the left lobe of the liver, issue at the transverse fissure of its under surface, there soon unite, and

form one main trunk, the hepatic duct. After running a short distance together with the portal vein, hepatic artery, and nerves, in a quantity of dense cellular tissue inclosed within the fold of the peritoneum, the hepatic duct meets and unites with the duct of the gall-bladder, or cystic duct. The tube resulting from the junction of the hepatic with the cystic duct is called the *ductus communis chole-dochus*: it is about three and a half inches in length, and terminates by opening, together with the duct of the pancreas, into the portion of the intestine named duodenum, at the distance of a few inches from the stomach.

The gall-bladder is a pyriform membranous sac, lodged in a shallow depression at the inferior surface of the liver, which communicates, as we have stated, with the excretory duct of the liver, by means of a tube called the cystic duct. [BILE.]

Diseases of the liver.—The liver is subject to all those general morbid changes which, depending on disordered actions of the bloodvessels, modification of the nutritive process, or alterations in the blood itself, may affect most organized parts of the body: such are inflammation (hepatitis), acute and chronic; hypertrophy and atrophy; induration and softening; and the different kinds of tumours or transformations of tissue, carcinoma, or cancer, medullary sarcoma, fungus hæmatodes, melanosis, and scrofulous tubercle. It is occasionally infested by parasitic animals (hydatids), which may likewise affect other parts of the body.

But the liver is also liable to other diseases which appertain to it specially, and are connected with its function—secretion. The chemical changes which give rise to the formation of bile in the liver may be so deranged, that one or all of the ingredients of that fluid are increased or diminished in quantity, or vitiated in quality, and such disorder of the secreting process may manifest itself in several ways: the imperfectly formed fluid passing into the intestines may cause irritation there, and consequently diarrhœa; or, being absorbed into the blood, may produce jaundice and its concomitant symptoms; or some of the ingredients of the bile may congregate into solid masses in the ducts of the liver or the gall-bladder, forming gall-stones. The diseased state of the liver, in which it becomes impregnated with an unnatural quantity of fatty matter, may also be reckoned among the diseases appertaining to the special function of the organ, for the bile naturally contains a large proportion of fatty matter (cholesterine), though the chemical composition of this substance, and that of the oil or fat with which the liver is impregnated in disease, appears to be different.

The treatment of diseases of the liver is regulated by the general principles according to which the cure of diseases in other parts is attempted, and will of course vary with the nature of the particular affection requiring it.

LIVERPOOL, a municipal and parliamentary borough and seaport of Lancashire, stands on the right or E. side of the estuary of the Mersey, in 53° 24' N. lat., and 2° 58' W. long.

Liverpool is first mentioned in a deed of Henry II. about the year 1173, at which time it was a ville and manor, but not a borough. In the year 1207 King John purchased the manor and granted a charter, by which he gave to all persons who

should take burgages or grants of land at Liverpool, on burgage tenure, all the rights enjoyed by the burgesses of any free borough on the sea in any part of England. This was the first charter of Liverpool, and although expressed in a few lines, it included everything that could be granted in the largest and most liberal charter. In the year 1227 Henry III. granted a second charter to Liverpool, confirming in detail to the burgesses all the local rights that were usually granted in those times to seaports and municipal towns. These charters were afterwards confirmed by Edward III. (1333), Richard II., Philip and Mary (1556), and Charles I. (1625). In the reigns of Edward III. and Richard II. the burgesses were authorized to raise rates to pave the town; and in the reign of Henry VIII. (1561), an improved harbour was constructed in the pool or arm of the sea which at that time ran along the S. and E. sides of the town, and with the river on the W. made it almost an island. The castle of Liverpool, probably built by King John, for there is no earlier mention of it in any deed of authority, stood in the middle of the town, at the point where St. George's Church now stands, and the streets sloped down from it towards the river and the pool.

Until the time of the colonization of the North American continent and the West India islands by England, the trade of Liverpool only extended to the W. coast of Scotland, to Wales, to the E. and S. coast of Ireland, and occasionally to France, Spain, and Portugal. The imports consisted of wool and linen yarn, which were in great demand even in those early times by the manufacturers of Manchester, and of wine and dried fruit from France and Spain. The exports consisted chiefly of Manchester goods, Sheffield cutlery, coals, and occasionally grain. During all this period Liverpool was a small place with only from 1000 to 1500 inhabitants; but there were then no great towns in the N. of England, and Liverpool was as large as any of the neighbouring towns except Chester, which was then much the richest place in the north-western division of England.

But when new colonies were established in Virginia, New England, Barbadoes, and numerous other points on the mainland or on the islands of America, the trade of Liverpool began to expand, and at the close of the civil war, in 1649, Liverpool had a considerable trade with America and the West Indies, as well as with other parts of the British Islands and the continent of Europe. The town suffered greatly in the civil war, having been twice besieged; once by Prince Rupert, who carried it by storm, and a second time by Sir John Meldrum, one of the commanders of the parliamentary army, who compelled the king's general, Sir Robert Byron, to surrender it to the Parliament. From the time of the Restoration to the Revolution of 1688, the commerce of Liverpool increased rapidly, and at the beginning of the eighteenth century nearly the whole of the Virginian tobacco trade, then the principal staple of America, was concentrated there.

In the reign of Queen Anne the corporation of Liverpool obtained power to form a wet dock and a dock for the building and repairing of ships at the entrance of the pool. A second dock of larger size was formed in the reign of George II. A third and still larger dock was constructed immediately after

the accession of George III. Two other large docks were constructed during the peace between the first American war and the French Revolution, and before the close of the century the Liverpool docks, either formed or authorized to be formed, extended nearly two miles in length from N. to S. During the present century they have been still more rapidly enlarged, so that they are now between five and six miles in length, independent of the immense docks which have been constructed at Birkenhead on the opposite side of the river Mersey. These docks, taken as a whole, now form the finest artificial harbour in the world, and accommodate the greatest trade.

The most important public buildings in Liverpool are the Town Hall; the Exchange Buildings, entirely rebuilt and greatly beautified and enlarged during the last three years; St. George's Hall, one of the most beautiful Grecian structures of modern times; the banks, and the large masses of offices built on a uniform plan, some of them in the very best style of architecture. In the Town Hall the ground floor contains the council room, several committee rooms, the mayor's, town clerk's, treasurer's, and town surveyor's offices; but some of these are about to be removed to the new public buildings which the corporation are erecting in Dale Street. The principal story of the Town Hall contains a very fine suite of rooms magnificently furnished, and approached by a noble staircase lighted from the dome. The saloon, two drawing-rooms, two ball-rooms, and the banquet-room, all communicating with each other, are noble apartments. The Exchange Buildings form, with the Town Hall, three sides of a quadrangular area which is used by the merchants of Liverpool as an Exchange. The news room, which is just finished, is one of the largest rooms ever erected for commercial purposes, being built to accommodate from 3000 to 4000 subscribers. The other buildings, designed for the underwriters of the port, with the cotton saleroom and other establishments, are also on a large scale. The Custom House, in which are also contained the dock offices, the excise office, the post office, the stamp office, and other public offices, is situate on the site of the old dock; the extreme length, measuring from E. to W., is 466 feet. St. George's Hall is a most elegant building. The eastern façade is 400 feet long, and has a colonnade, projecting centre, with depressed wings. Within the central projection is an ambulatory 26 feet wide: behind this is St. George's Hall, a noble vestibule or hall bounded on the N. and S. by the assize courts, to which it affords approaches.

Liverpool contains upwards of forty churches belonging to the Establishment; these, with the various episcopal and dissenting chapels, give a total of more than a hundred places of worship.

Numerous buildings devoted to charitable purposes have been erected in various parts of the town. The infirmary, the workhouse, the fever hospital, the lunatic asylum, with the numerous smaller hospitals and the dispensaries, are all most valuable and efficient establishments. There is also the Sailors' Home, of which the first stone was laid by Prince Albert in 1846. The Bluecoat School, established by Bryan Blundell in 1709, has accommodation for 250 boys and 100 girls, who are educated,

boarded, and clothed free of charge. There are also charitable schools for the blind, for the deaf and dumb, for male and female orphans, with corporation free schools, and others supported by different denominations of Christians. The Collegiate Institution, opened in 1845, is a fine Elizabethan structure, and is appropriated as a school for the higher branches of education. The Queen's College, formerly the Mechanics' Institute, is applied to equally valuable purposes. Amongst the other educational and literary establishments of Liverpool are the Brown's Institute, the Royal Institution, the Literary and Scientific Institution, and the extensive libraries of the Lyceum and the Athenæum. The borough jail is a large and well-managed prison. The county house of correction at Kirkdale stands within the limits of the borough.

The markets in Liverpool are on a very extensive scale. St. John's, which covers several acres, is open daily for the sale of meat, poultry, fruit, and garden vegetables. The fish market, on the opposite side of the street, is always liberally supplied.

Many of the modern commercial buildings are architectural ornaments to the town. Amongst them may be named—the Royal Bank, in the Italian style; the Royal Insurance Office, in florid Italian; the Union Bank, Grecian; Brunswick Buildings, on the model of the Farnese Palace; the Branch Bank of England, and the Commercial Bank Buildings. Many of the new ranges of offices exhibit a noble design and great richness of decoration, as Brown's Buildings near the Exchange, Tower Buildings, and several others.

The principal places of public amusement are St. George's Hall, where musical performances are given almost weekly, the Theatre, the Royal Amphitheatre, the Prince of Wales' Theatre, the Philharmonic Hall, one of the noblest music rooms in England, and the Wellington Assembly Rooms. Most of the public balls are given either at the Town Hall or at St. George's. Two or three small public gardens have already been opened, and the corporation has decided to form a new and splendid park in the Parliament Fields at a cost of 250,000*l*. Numerous public baths, formed at the expense of the corporation, are much resorted to.

The municipal borough of Liverpool is divided into sixteen wards, and is governed by sixteen aldermen and forty-eight councillors. The parliamentary borough returns two members to the House of Commons. Electors in 1866, 20,618.

No other town in Great Britain presents such a surprising increase in commercial prosperity as Liverpool. This is in a great measure owing to the impetus given to the cotton trade, and the perfection of communication wrought by the 'iron road,' which made Liverpool the depot of all species of merchandise and manufactures intended for exportation to the United States. Nor must the enterprise of its inhabitants be forgotten, which still operates to increase the prosperity and maintain the commercial influence of the second city in the United Kingdom. At the beginning of the last century its population consisted of only 5000 persons, and its shipping of about 80 vessels. In 1760 its population had increased to 25,780, and its vessels to 1245. The increase was still more rapid during the next forty years, for in 1800 it had 78,000 inhabitants, and about 5000 vessels entered and cleared annually. The great increase of the cotton trade was the cause of this wonderful improvement. In 1781 only 5,000,000 lbs. of raw cotton were imported; in 1791, 31,000,000 lbs.; and in 1800, 43,000,000 lbs. The value of the exports of cotton manufactures during the same period had increased from 355,000*l*. to 6,040,000*l*. But rapid as was this progress, it has been very much exceeded since, until at last Liverpool has become the most important commercial port in the world. The following figures will give the best idea of its progress from 1801 to 1861:—

Year.	Pop.	Vessels.	Tonnage.	Dock Dues.
1801	77,708	5,060	459,719	£28,365
1831	205,572	12,537	1,592,436	183,455
1861	443,938	21,095	4,977,272	444,417

The population is now (Sept., 1866) estimated at very nearly half a million, and the actual state of its trade will be seen from the annexed table:—

	Sailing.		Steam.		Total.	
	Vessels.	Tons.	Vessels.	Tons.	Vessels.	Tons.
Number of vessels registered, 1865,	2721	1,409,772	340	144,713	3061	1,554,485
Entries, coastwise, 1864,	4602	402,324	3426	1,069,417	8028	1,471,741
Clearances, ditto, “	4895	351,563	3349	1,009,834	8244	1,361,397
Entries from the colonies, “	1233	855,422	62	68,530	1295	923,952
Clearances to ditto, “	1260	841,503	87	92,137	1347	933,640
Entries from foreign countries, “	2812	1,015,073	860	759,497	3672	1,774,570
Clearances to ditto, “	2590	1,032,609	736	686,685	3326	1,719,294

The total number of entries of all kinds in 1865 was 12,607 (4,224,447 tons), and the clearances, 12,285 (4,010,705 tons); or together, 24,892 vessels, and 8,235,152 tons.

But perhaps the most striking idea of the vast commerce of Liverpool is furnished by the following figures, which give the value of British produce

exported from the twelve principal ports of the United Kingdom in the years 1863 and 1864. It will be seen that not only does it head the list, but that it actually exports more than all the others combined; and if every other port in the kingdom is added, it will still be found that Liverpool sends out, within a fraction, as much as all the rest:—

Ports.	Exports.	
	1863.	1864.
Liverpool, ...	£65,154,232	£72,748,031
London, ...	36,211,510	36,554,913
Hull, ...	13,556,254	16,052,398
Glasgow, ...	6,770,368	7,604,426
Southampton, . . .	4,071,991	4,726,513
Newcastle, ...	1,894,281	1,879,041
Leith, ...	1,552,899	1,765,441
Greenock, ...	455,021	502,873
Bristol, ...	341,674	290,113
Cork, ...	108,102	137,435
Dublin, ...	38,196	34,540
Belfast, ...	12,041	21,660
Total, ...	130,166,569	142,317,384

Cotton goods, of course, form by far the largest items in producing the above vast amount, but there are also some very large exportations of other articles. We annex all above 1,000,000*l.* in value which were shipped in 1864, and insert the quantities wherever possible:—

	Quantities.	Value.
Cotton yarn, ...	27,412,775 lbs.	£3,246,448
Cotton manufactures, piece goods, ...	1,266,044,528 yds.	30,932,572
Hosiery & small wares, Haberdashery and millinery, ...	—	1,155,174
Hardware & cutlery, .	—	1,942,700
Linen yarn, ...	—	1,976,632
Linen manufactures, piece goods, ...	14,951,908 lbs.	1,098,676
Machinery of all kinds, Iron of all kinds, . .	144,746,220 yds.	5,219,696
Copper, ...	737,836 cwt.	1,783,349
Woollen manufactures, Worsteds & mixed stuffs, Flannels and carpets, .	1,502,964 tons.	4,867,451
	737,836 cwt.	1,525,668
	22,289,950 yds.	3,090,153
	85,910,597 yds.	3,980,349
	13,211,070 yds.	1,301,616

The import trade of Liverpool is also exceedingly large, and in some articles far surpasses that of London. The official returns do not give the value of the different articles imported at each port, but the quantities of some of the most prominent items landed in 1864 will be found below:—

Cocoa, ...	2,591,720 lbs.
Coffee, ...	6,914,002 "
Wheat, ...	6,347,560 cwt.
Indian corn or maize, .	1,610,497 "
Flour, ...	1,939,683 "
Cotton (raw), ...	7,086,657 "
Madder, ...	216,807 "
Currants, ...	248,618 "
Hemp, ...	328,062 "
Jute, ...	623,820 "
Hides (wet), ...	251,808 "
Hides (tanned), . . .	1,717,179 lbs.
Palm Oil, ...	440,429 cwt.
Bacon and hams, . . .	776,867 "
Cheese, ...	349,954 "
Lard, ...	155,326 "
Rice, ...	1,670,386 "
Saltpetre, ...	453,843 "

Silk (raw), ...	298,922 lbs.
Pepper, ...	2,864,930 "
Rum, ...	1,191,899 galls.
Brandy, ...	766,618 "
Sugar (unrefined), . .	2,248,786 cwt.
Tobacco (all kinds), .	31,484,972 lbs.
Wine, ...	1,385,496 galls.
Wool, ...	53,035,883 lbs.

The customs' revenue collected at Liverpool in the year ended 31st March, 1866, amounted to 2,771,712*l.* In 1821 the total was 1,488,072*l.*; in 1831 it was 3,562,114*l.*; in 1841 it was 4,607,326*l.*; in 1851 it was 3,366,284*l.*; in 1861 it was 3,343,518*l.* The diminution in the receipts since 1841 is due entirely to the abolition of duties on many hundred articles of importation, and to the great reduction of rates on sugar, tea, spirits, and wine, the results of Mr. Gladstone's liberal financial policy.

LIVERPOOL, ROBERT BANKS JENKINSON, EARL OF, a distinguished statesman, and Premier of England, was born in 1770. He was educated at the Charterhouse; from which he proceeded to University College, Oxford. Under the ægis of his father, Charles Jenkinson, first earl of Liverpool, he entered with every advantage on the political arena of his country at a most critical period of its history. In 1790 he was returned as member for Rye, and in 1796, having received the title of Lord Hawkesworth, on the elevation of his father to the earldom, he was appointed a commissioner of affairs for India. In 1801 he became secretary of state for foreign affairs; and four years afterwards was appointed head of the home department. In 1812 he was appointed prime minister. On the dissolution of the Addington administration, he resigned his position; but in 1817 he was re-appointed to the same office. On the death of his father, in 1818, he succeeded to the earldom. He died in 1828.

LIVERWORTS, or LICHENS, a family of plants belonging to the class *Cryptogamia*, of which a definition is given under LICHENS. The order consists of between fifty and sixty genera, which are divided by Fries into four sub-orders:—*Hymenothalami*, *Gasterothalami*, *Idiothalami*, and *Coniothalami*: to these some systematists add *Byssaceæ*. These are again subdivided into several tribes, each tribe comprising several genera. The species of the genus *Usnea* are amongst the most common of the Lichens which cover the trunks of aged trees. The species of the genus *Everina* are common in Great Britain. One of them, *E. prunastri*, has a peculiar power of imbibing and retaining odours, and on this account is in much request as an ingredient in perfumed cushions and sweet pots. It has been recommended as a remedy in pulmonary affections. It is frequently found on the oak and other trees. The species of *Parmelia* are exceedingly numerous. One of the most common throughout Europe is the *P. parietina*, Yellow Moss. It has a very bitter taste, which has caused it to be used as a tonic in medicine, and it has been recommended as a remedy in intermittent fever. *P. tartarea* yields the dye known by the name of Cudbear. *P. parella* affords the substance known as Litmus, or Lacmus. One of the species of the genus *Sticta*, *S. pulmonacea*, has been used as a substitute for the Iceland Moss. It is used in Siberia for giving a bitter flavour to beer. It is a

native of Great Britain, and is found on the trunks of trees in mountainous districts, almost entirely covering them with its large shaggy fronds. The tribe *Lecidinæ* embraces the important genus *Cladonia*, and also *Cenomyce* and *Scyphophorus*, which are often only regarded as subgenera of *Cladonia*. They have both been used in medicine as astringent and febrifuge. (See Plates 1, 2, 'Lichens.')

LIVERY. During the earlier period of English history, when the feudal system had permeated all ranks of society, the wearing of livery was not confined to domestic servants as it is now. Each class wore the livery of their superiors: the armed retainers wore that of the noblemen whom they served; the son of a gentleman wore that of a knight; and the knight that of the duke; and even the duke's son, as page to the prince, wore the prince's livery. The colours of the livery were then, and are usually now, borrowed from the armorial bearings of the family whose livery is worn; being generally the tincture of the field and that of the principal charge, or the two tinctures of the field, where it has two. The royal family of England have at times adopted other colours than those found in their arms. The Plantagenets had scarlet and white; the Tudors, white and green; the Stuarts, yellow and red; and the House of Brunswick, scarlet and blue. In London, the freemen of the trade-guilds or companies, are called liverymen; and it was anciently the custom to allow each of them twenty shillings a year, towards the purchase of a suit of the livery of their respective companies, that they might make a splendid appearance in civic pageantry. The liverymen elect the common council-men, sheriffs, and aldermen of the city; and before the Reform Bill of 1832 they were the exclusive constituency of the city of London.

LIVIVS, with his full name, **LU'CIUS LIVIVS ANDRONICUS**, was the first person who introduced a regular drama upon the Roman stage. (Liv., vii. 2.) The time and place of his birth are uncertain; but his first play was probably exhibited 240 B.C., in the year before Ennius was born. The fragments of his works which have come down to us are too few to enable us to form any opinion respecting them: Cicero says that they were not worth being read a second time.

LIVIVS, TITUS, the Roman historian, was born at Patavium (Padua), B.C. 59. We possess very few particulars respecting his life. He appears to have lived at Rome, and to have been on intimate terms with Augustus, who used, according to Tacitus ('Ann.' iv. 34), to call him a Pompeian, on account of the praises which he bestowed upon Pompey and his followers. He also encouraged the historical studies of Claudius, afterwards emperor. He died A.D. 17, in his seventy-sixth year.

Livy's great work, which was originally published in 142 books, gave an account of the history of Rome, from the earliest period to the death of Drusus, B.C. 9. Of these books only 35 are now extant, namely, the first ten, which contain the history of the city to B.C. 293; and from the twenty-first to the forty-fifth inclusive, which commence with the Second Punic War, B.C. 218, and continue the history to the conquest of Macedon, B.C. 167. There also exist brief epitomes of the lost books, as well as

of those which have come down to us, though these have been frequently supposed, but without sufficient reason, to have been compiled by Florus. We have, however, only epitomes of 140 books; but it has been satisfactorily shown by Sigonius and Drakenborch on Livy, 'Ep.' 136, that the epitomes of the 136th and 137th books have been lost, and that the epitome of the 136th book, as it is called, is in reality the epitome of the 138th. The fragments of the lost books, which have been preserved by grammarians and other writers, are given in Drakenborch's edition. That portion of Roman history which was contained in the lost books has been written in Latin by Freinshemius.

We have no means for ascertaining when the whole of the history was completed, though there are indications of the time at which some particular portions were written. Thus in i. 19, he mentions the first shutting of the temple of Janus by Augustus after the battle of Actium, B.C. 29; whence we may conclude that the first book was written between this year and B.C. 25, when it was closed a second time. He must also have been engaged on the 59th after B.C. 18, since the law of Augustus, 'De maritandis ordinibus,' passed in that year, is referred to in its epitome.

Tacitus and Seneca, among the later Roman writers, speak in the highest terms of the beauty of Livy's style and the fidelity of his history—praises which have been constantly repeated by modern writers. But while most will be ready to admit that his language is eloquent, his narrative clear, and his powers of description great and striking, it can scarcely be denied that he is deficient in the first and most important requisites of a faithful historian—a love of truth, diligence and care in consulting authorities, and a patient and painstaking examination of conflicting testimonies.

The best editions of Livy are those by Crevier, 1735–40; Drakenborch, 1738–46; Ernesti, 1804; Ruperti, 1817; Döring, 1816–24; and Kreyssig, 1823–27. His Roman History has been translated into most European languages; the most esteemed are the translations in German by Wagner (1776–82) and Cilano (1777–79); in Italian, by Nardi (1755); in English, by Philemon Holland (1600, 1659), by Baker (1797); and in French, by Dureau de la Malle and Noel (1810–12; and 1824).

LIVONIA, one of the Baltic provinces of Russia, situated between 56° 34' and 59° 3' N. lat., 28° 20' and 27° 38' E. long., is bounded N. by Esthonia, E. by Lake Peipus and Pskow, S. by Vitepsk and Courland, and W. by the Gulf of Livonia or Bay of Riga. The area is 18,773 square miles; the population at the last census was 883,681, very mixed, and mostly Lutherans. The surface is generally level, with here and there some hills, which rarely exceed 100 feet in height. Livonia is covered with vast forests, lakes, rivers, marshes, and heaths. The soil on the sea-coast, which is bounded by high cliffs, is very sandy: in the interior, sand, clay, loam, and moorland alternate, but there are also many very fertile tracts. In the south, especially on the banks of the Duna, there is some very picturesque scenery. Most of the forests and marshes are in the west. Of the lakes, 1120 in number, the most considerable are—the great Lake of Peipus, crisscrossed by a narrow channel with that of

Pskow on the north-east; and the Lake Wirzjærw, 80 square miles in extent, in the centre of the province, which is connected by the Great Embach river with Lake Peipus. The principal river is the Düna, which is the boundary between Livonia and Courland till it reaches Kirchholne, whence it runs north-west into the Bay of Riga at Dünamunde. The smaller rivers and streams are very numerous.

The climate is cold and raw from October till the end of May; very hot in the three summer months. September has some fine days, but the nights are often frosty.

The chief occupations of the inhabitants are agriculture and the distillation of spirits. The country produces rye and barley, flax, hops, hemp, and linseed. The fruit, such as apples, plums, and cherries, is very indifferent. There are some good horses on the estates of the nobles, but those of the peasantry are small and of little value. The horned cattle are small; sheep of the German breed are kept by the nobles; the peasants have an inferior breed, the coarse black wool of which is manufactured into cloth. Goats, swine, and domestic poultry are kept. There is abundance of game, white and gray hares; the other wild animals are bears, wolves, lynxes, foxes, beavers, otters, martins, badgers, and squirrels. The Lake Peipus abounds in fish. There are no minerals of importance nor manufactures, except in Riga. The exports are corn, hemp, flax, and linseed; the imports are salt, iron, lead, colonial produce, wine, manufactured goods, and articles of luxury.

The chief towns in the province of Livonia are, RIGA; ARENSBERG, or ARENSBURG; DORPAT; Pernau, a well-built fortified town and port, with 6850 inhabitants, at the mouth of the Pernau, which flows from the Wirzjærw Lake, and falls into the north-eastern part of the Gulf of Livonia. Only vessels of 6 feet draught can come up to the town; those of larger size anchor in the roads about a mile from the harbour, where they are unloaded by small craft. The exports are chiefly corn, flax, and hemp; the imports consist of wine, brandy, salt, drugs, and various kinds of manufactured goods. The total value of the exports in 1842 was 103,015*l.* 16*s.* 2*d.*, which represents the freight of 75 ships of 4451 tons' burthen. Wenden, north-east of Riga, situate on the Aa, which drains the centre of the province, has a population of 2500. The fortress of Dünamunde, built on an island, in the estuary formed by the embouchures of the Düna and the Aa, deserves mention for its light-house, and as defending the entrance to the harbour of Riga.

LIVORNO. [LEGHORN.]

LIVRE, an ancient French coin. The word is derived from the Roman *libra*, or pound. The livre was of two kinds—Tournois and Parisis, the latter being equal to $\frac{1}{14}$ th of the former. This was on account of the rate of money, which was one-fourth higher at Paris than at Tours. Under the decimal system accounts are now kept in francs of twenty sons, of ten decimes each, and each decime is divisible into ten centimes. Eighty francs are worth eighty-one livres Tournois. Livre was also the ancient French unit of weight, and was equal to 17·267 oz. avoirdupois; the kilogramme has taken its place. [GRAMME.]

LIXIVIVM, a term which is synonymous with

ley. It was used by the older chemists to signify a solution of an alkali in water.

LIZARD. [LACERTIADÆ.]

LIZIER, ST. [ARIÈGE.]

LLAMA (genus *Auchenia*), a genus of Ruminants of the family *Camelide*, and representing in the mountains of Peru and Chili the camels (*Camelus*) of the deserts of Arabia or Bactria. In dentition, at least very nearly; in outward form, excepting that there is no hump on the back; in the general structure and cellular apparatus of the stomach, with the concomitant power of abstaining for a long time from water; in the expression of the large, full, overhung eye; in the mobility and division of the upper lip; in the fissured nostrils; in the slenderness of the neck; and in the long woolly character of the clothing—the Llama and the camel exhibit striking points of agreement. In the feet, however, the difference is very considerable. The feet of the camel are broad and extensively cushioned below, being in fact precisely adapted to the sands of its congenial desert; whereas the slender, elastic, claw-tipped foot of the Llama is destined for the crags of the Cordilleras.

The foot of the Lama consists of two springy toes completely divided, each having a rough pad beneath, and at the tip a strong hoof; these hoofs are pointed at the extremity, and hooked down somewhat like a claw; they are compressed laterally, and the upper surface presents an acute ridge, while the under surface is linearly concave, a form well fitted for security on the mountain range.

The Spaniards, when they conquered Peru and Chili, found the Llama, which seems to have been the only beast of burden possessed by the natives as a domestic animal: it was not merely a beast of burden—its flesh was eaten, and its wool was woven into cloth. It was at once pack-ox and sheep, and was described by the early Spanish writers as a sort of sheep. Its skin was also prepared as leather.

One of the labours to which the Llama was subjected was that of bringing down ore from the mines among the mountains. Its ordinary load was 80 or 100 pounds, and its average rate of travelling with this burden was from 12 to 15 miles a day, over rugged paths and through mountain passes; but, like the camel, if too heavily laden, it would lie down, and obstinately refuse to proceed; nor would it bear to be urged beyond its accustomed pace. Gregory de Bolivar estimated that in his day 300,000 were employed in bearing the produce of the mines of Potosi alone, and 4,000,000 annually killed for food.

Augustin de Zarate, treasurer-general in Peru in 1544, in his account of the conquest, speaks of the Llama, as it was observed in the mountains of Chili, as a sheep of burden. He says that, in situations where there is no snow, the natives, to supply the want of water, fill the skins of sheep with that fluid, and make other living sheep carry the skins; for he remarks that these Peruvian sheep are large enough to serve as beasts of burden. De Zarate evidently had the eye of a zoologist, for he says that these sheep resemble the camel in shape, though they have no hump. He states that they can carry about 100 pounds or more, that the Spaniards used to ride them, and that their rate of travelling was 4 or 5 leagues a day. His description appears to be that

of an eye-witness, and bears upon it the impress of truth. When they are tired, says De Zarate, they lie down, and the load must be taken off, for neither beating nor help will make them get up. Their weariness is manifested in a very disagreeable way when a man is on one of them; for our author says that, if the beast is pressed on under such circumstances, it turns its head and discharges its saliva, which has a bad odour, into its rider's face. He speaks of them as of great utility and profit to their masters, praises their good and fine wool, particularly that of the species named *Pacas*, which have very long fleeces, and shows that their keep costs little or nothing, either in money or trouble; for they are satisfied with a handful of maize, and are able to go four or five days without water. He declares that their flesh is as well flavoured as that of a fat Castilian sheep, and notices the public shambles for the sale of it in all parts of Peru then frequented by these animals. But he remarks, this was not the case on the first arrival of the Spaniards; for when an Indian killed a sheep at that time, his neighbours came for what they wanted, and then another Indian would kill a sheep in his turn.

Similar information is given us by the old writers, as John De Laet (folio, Leyden, 1633), D'Acosta, Hernandez, Captain G. Shelvocke (1719-22), Molina, and many others.

As a beast of burden in its native mountains, whether of Peru or Chili, the Llama has yielded to the mule. But it is still most important on account of one of its qualities which attracted the attention of the ancient Peruvians; it is a woolbearer, and that of no ordinary kind, the wool approximating in its character to silk. Large quantities of this material are imported into Europe for the manufacture of shawls and other delicate fabrics, and the improvement of this material has been made a subject of earnest consideration and trial. The older writers leave us in considerable doubt as to the number of species belonging to the genus *Auchenia*. It would appear, however, that the domestic Llama, a stout strong animal, variable as to colouring, but mostly white, is the descendant of a wild species termed the Guanaco, and that the Vicuña, and the Paca or Paco, are still further distinct.

The following species of the Llama are now generally recognized:—

1. *Tame and Wild*.—The Guanaco, Guancu, Huanco (*Auchenia llama*).
2. *Tame and Wild*.—The Paco, Paca, or Alpaca (*Auchenia alpaca*, Desm.)
3. *Wild*.—The Vicuña, Vicugna, Vigognia, &c. (*Auchenia vicuña*).
4. *Wild*.—The Taruga, or Taruca (*Auchenia taruca*), a doubtful species, described by De Laet as a solitary animal of a dark burnt brown colour, with pendulous ears, larger than the Vicuña, but distinct from the wild Guanaco.

Some zoologists consider that there are only two truly distinct species, the Guanaco and the Vicuña; if so, the varieties must be very marked. In the tame Guanaco (or Llama) the wool is long and coarse; in the wild Guanaco it is much finer and softer, and of a cinnamon brown. In the Vicuña, a small species inhabiting the mountain ranges on the verge of perpetual snow, the wool is exquisitely fine, but short,

and of a pale yellow brown. Thousands are annually killed in Peru for this material alone.

In the Paca, or Alpaca, the domestic breed of which is often of an intense lustrous jet black, the wool falls in long flakes, glossy and silken, reaching down to

Llama (*Auchenia llama*).

the knees. This is the Paco-llama of De Laet. With respect to the Taruga of De Laet, nothing is known. Of Alpaca silk-wool vast importations are yearly made into this country; it is worked up into exquisite textures, chiefly at Paisley, Glasgow, &c.,

Vicuña (*Auchenia vicuña*).

and great quantities of yarn, varying from 6s. to 12s. 6d. per pound, are sent to France.

The habits of the Guanaco, or Wild llama, are much better known than those of any other species, and have been described at length by Mr. Darwin in the 'Voyage of the Beagle.' This species lives in the highlands of Patagonia, Chili, and Peru, descending into the valleys on the approach of winter. It is gregarious, wild, fleet, active and inquisitive, and, takes readily to the water. General colour, rich rufous brown; head and part of the neck gray; tail a little raised up and curled down; neck long; height at the top of the shoulders, 3½ feet. (See Bennett, Darwin, and others.)

Attempts to naturalize the Llama, Alpaca, and Vicuña in Europe have been made with spirit and judgment, but hitherto without decided success. In Australia, through the exertions of Mr. Ledger, it has been successfully introduced, and its wool is becoming one of the staple exports of the British colonies in that vast island.

No fossil species of Auchenia has yet been discovered; but Mr. Darwin brought home from South America the remains of a most interesting animal nearly allied to the Llamas, which Professor Owen has characterized under the name of *Macrauchenia*. The cervical vertebrae in this form present the same character in the absence of the holes for the vertebral arteries in the transverse processes as in the Llamas and Camels.

LLANRYST. [DENBIGHSHIRE.]

LLANTRISAINT. [GLAMORGANSHIRE.]

LOYD'S, a name given to a set of offices on the first floor of the Royal Exchange, London, which is the great centre for all relating to shipping and marine insurance. The name arose from the fact that the first voluntary association of underwriters was at Lloyd's private coffee house. It has now grown into a vast organization, transacting an insurance business to the amount of forty millions annually. The offices of Lloyd's are very magnificent; the subscribers' room for the business of underwriting is 100 feet long by 48 feet wide, and communicates with a large library and reading-room. These contain a valuable collection of maps and charts, and instruments of navigation. There is also a captains' room, where ships are sold, and captains and owners meet for business; a commercial club-room, board-room, and clerks' offices.

The society of Lloyd's is managed by a committee selected from the members, and the expenses are defrayed by fees and annual subscriptions. None but those who have paid the fees are allowed to transact business there as insurance brokers or underwriters. Every day is registered a list of all vessels arrived or departed, all casualties at sea, and shipping intelligence from every part of the world, which is distributed over the country every evening by the publication of *Lloyd's List*. There is scarcely a port in the world without an agent of Lloyd's, who gives the earliest possible information of all shipping movements. *Lloyd's Register of British and Foreign Shipping* is published annually, and contains an accurate classification of the mercantile marine of the kingdom, and of the foreign vessels trading thereto. This information is supplied by paid surveyors at each of the ports of the United Kingdom. The committee of Lloyd's also give rewards to those captains and others who render services to ships in distress, and exercise a general supervision over the maritime interests of the country.

LO, ST., the capital of the French department of Manche, is situated in $49^{\circ} 6' 59''$ N. lat., $1^{\circ} 5' 55''$ W. long., at a distance of 157 miles W. from Paris, and has a civil tribunal and of commerce, a college, and 9810 inhabitants. The central part of the town

stands on a rocky eminence above the Vire, from which the other streets, all irregularly and badly built, extend down the slopes in all directions. The square called Champ-de-Mars is prettily laid out with avenues of trees. The most remarkable structures are the church of Notre-Dame, in which are fine painted windows, the gift of Louis XI.; the church of Sainte-Croix, the best preserved edifice in the oldest Norman style in France; the church of St.-Thomas, which is now a corn market; and the tower in the garden of the prefecture, which is all that remains of the former defences of the town. The chief manufactures of St.-Lô are drugget, woollen yarn, tape, lace, linen, and leather. There is a considerable trade in horses for the French cavalry, in cattle, corn, small wares, cloth, &c. The town has a museum, dye-houses, and bleaching establishments.

LOACH. [COBITTS.]

LOADSTONE OR LODESTONE, the natural magnet, or magnetic iron ore ($\text{Fe O} + \text{Fe}_2 \text{O}_3$), has been long known for its power of attracting small pieces of iron, and making them adhere to its surface. Loadstone is one of the most valuable of the iron ores. It is sometimes found in nature beautifully crystallized in regular octahedral crystals. For the most part it is of a dark gray colour with a metallic lustre. A careful examination of this substance shows that its attractive force for particles of iron is greatest at certain points, while elsewhere it is weak or even absent. These points are named its poles, and the loadstone is on this account said to be endued with magnetic polarity. 'If one of the poles of a natural loadstone be rubbed in a particular manner over a bar of steel, its characteristic properties will be communicated to the bar, which will then be found to attract iron-flings like the loadstone itself. Farther, the attractive force will appear to be greatest at two points situated very near the extremities of the bar, and least of all towards the middle. The bar of steel so treated is said to be magnetized, or to constitute an artificial magnet.'

LOAM, a soil compounded of various earths, of which the chief are silicious sand, clay, and carbonate of lime, or chalk. The other substances which are occasionally found in loams, such as iron, magnesia, and various salts, are seldom in such proportions as materially to alter their nature. Decayed vegetable and animal matter, in the form of humus, is often found in loams in considerable quantities, and the soil is fertile in proportion. [SOIL.]

LOANGO, on the west coast of Africa, extends from Cape Lopez Gonsalvo in $0^{\circ} 44'$ S. lat., to the river Congo or Zaire, which separates it from Congo in about 6° S. lat. *Loango*, the capital town, stands in a large plain, at the distance of 3 miles from the sea, in $4^{\circ} 40'$ S. lat., 12° E. long. The town is said to be 10 miles in circumference, and the population, including the suburbs, about 20,000. It is the place of residence of the king, whose government, like that generally prevalent among the barbarous tribes of this part of Africa, is the most absolute species of despotism.

A great part of the country is covered with thick woods, which abound in game, and it is only mountainous in the interior towards the south. In the north it possesses some lakes of considerable extent, from which, and from the mountains, many rivers

descend to the sea. The climate is excellent, the soil is rich, and produces potatoes, gum, enormous sugar-canes, palms, manioc, maize, and a pulse called *msangen*. The wild animals are tiger-cats, ounces, and hyenas.

LOANO. [ALBENGA.]

LOASA'CEE, a small natural order of polypetalous Exogens, consists of herbaceous and frequently annual plants, covered with stinging hairs, which cause considerable pain by the wounds they inflict.

LOBEL, or L'OBEL, MATTHEW, one of the founders of the science of systematic botany, was born in Flanders, in the year 1558, travelled in various parts of the middle and south of Europe, and finally settled in England, where he became physician to James I. He is chiefly known now as the author of botanical works illustrated by great numbers of figures, of which there are above 2000 in his '*Plantarum Historia*,' a folio work published at Antwerp in 1576, and still referred to by critical writers on systematic botany. But his name deserves mention more particularly as that of the first naturalist who devised the present method of arranging plants in their natural orders, rudely indeed, but with sufficient distinctness. Lobel died at Highgate, near London, in 1616. The genus *Lobelia* was dedicated to him by Linnæus.

LOBELIA'CEÆ, an important natural order of monopetalous Exogens. The species principally inhabit the warmer parts of the world. They abound in a milky juice, which in all is acrid, and in some so intensely so as to produce dangerous or even fatal consequences when applied to the surface of the body or taken internally. Among the most virulent is the *Hippobroma longiflorum*, a West Indian species, and the *Lobelia tupa*, a Chilian plant now common in gardens. Certain species, however, have proved, in skilful hands, valuable curative agents, especially the *Lobelia inflata*, or Indian tobacco, which is an annual plant, growing in most districts of North America, of which the oval obtuse leaves are used in medicine. The action on the human system is nearly the same as that of tobacco when chewed, producing a copious flow of saliva, and if swallowed in a considerable dose, causing great relaxation of all muscular structures, including the heart and arteries, accompanied with debility and cold perspirations, and also paleness of the surface. In large doses it proves decidedly poisonous. It frequently acts as an emetic and expectorant when given in small and regulated doses.

LOBO, JEROME, a native of Lisbon, entered the order of the Jesuits, and was ordered to the missions in India. He arrived at Goa in 1622, and volunteered for the mission to Abyssinia. He remained at Fremona for several years as superintendent of the missions in that kingdom, but was compelled to fly with the rest of the Portuguese in 1634, on account of the persecutions which they experienced from the native government and the Abyssinian priests. He exerted himself with the utmost vigour and perseverance to re-establish the influence of the Roman Catholics in Abyssinia, but meeting with neither assistance nor encouragement from either the court of Spain or the pope, he was obliged to relinquish the attempt.

In 1640 he returned to India, and became rector

and afterwards provincial of the Jesuits at Goa. In 1656 he returned to Lisbon, and in 1659 he published the narrative of his Journey to Abyssinia, under the title of '*History of Ethiopia*.' The whole was translated into English, from the French of the Abbé le Grand, by Dr. Johnson in 1735. Lobo died at Lisbon in 1678.

LOBO'TES (Gr. λοβός, 'a lobe'), a genus of fishes, of the family *Chaetodonidæ*, in which the body is thick, broad, and ovate, and the pectoral and caudal fins rounded.

LOBSTER. [ASTACUS.]

LOCAL ANÆSTHESIA IN SURGERY. The parts operated upon are rendered insensible to pain by the spray of rectified sulphuric ether: the ether employed for the purpose is called 'Anæsthetic Ether; it has a specific gravity of 0.720 (60° Fahr.) The ethereal spray is developed by a hand bellows, and is projected upon the skin through a fine jet. The parts subjected to the influence of the spray become, in less than a minute, perfectly blanched and deprived of sensation through the refrigerating effects of the ether. It is well known that chloroform renders the whole system insensible to pain, the patient being quite unconscious. By local anæsthesia, on the other hand, the sensibility of a part can be temporarily destroyed without sacrificing the consciousness of the individual. Moreover, one great objection to the employment of chloroform is the great risk attendant on its administration; in certain organic diseases it cannot be used with safety, and may indeed be contra-indicated altogether. In several instances chloroform has caused death. 'Chloroform takes away pain, but it may also take away life.' From local anæsthesia no fatal effects or bad consequences can possibly follow; and there is every probability that, although it will never supersede chloroform altogether, it will do so to a large extent in the minor operations of surgery. Many operations have already been performed under the influence of local anæsthesia with the most satisfactory and gratifying results. The local anæsthetic process not only annuls the pain of the surgeon's knife, but also in a great measure prevents the attendant hæmorrhage. Experience has shown that it does not impair the vitality of the tissues, or interfere with any process of repair which may subsequently be set up. Some incredulity at first prevailed in regard to the advantages of local anæsthesia, but recent experience has dispelled every doubt. The honour of this invaluable discovery is due to Dr. Richardson of London; and the great rapidity with which this method of inducing local anæsthesia has been adopted by the profession affords sufficient evidence of its efficiency and practical utility. The principle may not be altogether novel, but Dr. Richardson may justly claim priority for originating a practice which cannot fail to prove an inestimable boon. It may here be stated, that some years ago it was proposed to induce local anæsthesia by means of ice, but this was found a very tedious and uncertain process. The sulphuret of carbon has been very recently proposed for this purpose by Professor Delcominette, of Nancy. Various painless operations have been performed under the local influence of this agent. One great drawback, however, to the use of the sulphuret of carbon is its extremely disagreeable odour.

LOCARNO. [TICINO.]

LOCHABER. [INVERNESS-SHIRE.]

LOCHMABEN. [DUMFRIES-SHIRE.]

LOCK, a fastening by means of a movable bolt, which bolt is projected by the action of a key, and cannot be withdrawn except by the application of a similar key.

Locks possessing considerable merit are of very great antiquity. The most ancient is an ingenious contrivance described by Mr. Bonomi in his 'Nineveh and its Palaces.' It consists of an arrangement of loose pins so adjusted as to drop into corresponding holes in the upper side of the bolt whenever the bolt is thrown. The bolt can then only be withdrawn by first lifting the pins out of the bolt, which is effected by means of a very simple lifting key.

Practically all locks that are actuated by keys now in use may be ranged under one of three classes: the ward lock, the slide lock, and the lever lock. The ward lock is of almost unknown antiquity, keys on this principle having been found in the ruins of Pompeii and Herculaneum. The drawings in the Plate, marked fig. 1, are copies of keys found at these places, the keys themselves have been deposited in the British Museum; many allusions apparently to a lock of this kind are found in the oldest writings extant. It consists of an arrangement of obstacles called 'wards' for preventing any but the proper key being turned in the lock for the purpose of throwing the bolt. These locks are still in very general use, and perhaps afford a nominal security sufficient for ordinary purposes, although against picking and other methods of skilled burglary their security is very small indeed.

In 1784 and 1817 Joseph Bramah, the celebrated engineer, patented a most ingenious invention, which has become well known as the 'Bramah lock.' This invention, in its present complete form, consists in the introduction of a series of slides radiating around the key-pin, which slides may be regarded as a continuation or multiplication of the cleft portion of the ordinary key; only in this case such cleft portions, instead of being, as they might be, arranged around the key, are retained in the lock itself, and made to take their correct position with reference to the wards by the insertion of the key: the wards in this lock consisting simply of a series of studs or plates around the circumference of the slides. Thus the 'barrel' of the lock, namely, that portion which holds the slides, becomes, in fact, in its movement a portion of the key, and acts as one with it in throwing the bolt. Fig. 2 shows a section of a complete Bramah or Slide lock, together with the key, in the shaft of which the cuts may be seen, to receive the slides of the lock. Several important improvements have been added to this ingenious lock, especially by Larkin, Cotterill, and Mappin. Its great merit is the neatness of its form and the smallness of the key required.

Lever locks differ from all variations of the Ward lock in the fact that instead of offering obstructions to the turning of a wrong key in the lock, they depend for their security on obstructing the passage of the bolt itself, unless the rightful key be used in the attempt to throw it. This object is attained by arranging a number of levers close to and parallel with the bolt. They consist generally of a series of

plates with an up and down motion, working on and held together by a common pin. In each of these plates a passage or gating is cut, so as to allow a stump, or projection from the bolt, to pass through the gating only when the plates are raised to a certain given height. By varying the altitude of the passage or gating in each lever, and forming lifting steps in the key to correspond, a new and important principle of security is obtained. Fig. 3 shows a mortise lock for a room door, and has been selected for illustration as being one of the most complete of its kind. B is the bolt; T shows a series of levers with the open spaces, and passages called "gatings" through which the stump passes. This stump may be seen in the open space to the left, retaining the bolt in the position of being locked; when the bolt is withdrawn, or in other words, the lock unlocked, this stump will be in the inner gating. L shows the position of the latching bolt; s the bolt spring, and F the follower (Hobbs & Co.'s patent) which actuates the bolt.

The first introducer of the lever principle was Robert Barron, who in 1778 patented the application of movable levers for arresting the return of the bolt until they were raised to the required height. These levers he used in combination with ordinary wards. In 1790 Moses Bird patented a series of locks constructed on the true lever principle, and may be regarded as the originator of the present lever lock. In his specification he shows a key formed for lifting twelve levers. The modifications of this principle which have since been devised by many different inventors are too numerous to allow of special mention. We must, therefore, confine ourselves to the more important and substantial improvements.

The first of these is the 'detector lock,' invented by Jeremiah Chubb, and patented by him in 1818. Its object was, in addition to preventing the bolt from being withdrawn by any but the proper key, to give notice to the owner of any attempt being made with a wrong or false key; hence the use of the word 'detector.' If the reader imagine a scale beam to be placed over the levers (shown at T, fig. 3) with clutch ends, to retain the levers should they be raised too high by a false key, an idea of this 'detector' may be obtained. The 'Chubb lock' of the present day contains the same detective movement, with many additional contrivances to give increased security. The principal of these are, first, serrated or notched gatings to the levers, similar to a plan described in Bramah's patent for 1817 as applied to his slides, and again in Strutt's patent of 1819 as applied to his 'new-shaped tumbler or lever lock;' and secondly, the covering curtain of the keyhole invented by De la Fons, and patented by him in 1846. Great credit is due to the eminent firm of Chubb and Son, who have done so much to introduce this lever lock to the public, and to bring it into more general use.

The next important step in the development of the lever lock was made by A. C. Hobbs, who in 1852 patented his celebrated 'protector lock.' This invention consists of an ingenious contrivance, by which it is made impossible for any one to put a pressure upon the levers, and so feel their way to the several gatings through which the bolt stump passes

when the bolt is thrown; and is now universally admitted to be an effectual security against picking. The form of the 'protector' very much resembles a steelyard; it is placed at the back of the bolt, & the slightest pressure against the stump working between the gatings is taken by the long arm of the protector, and thus frees the levers from the only means by which the locks can be picked. This principle marks a new era in the history of locks, and has formed the foundation of many subsequent inventions for the purpose of rendering locks unpickable. Among such inventors may be mentioned Dennison, Tucker, G. Price, and O'Connell. A still further advance has since been made by J. M. Hart, who in his patent of 1861 describes a method of protecting the lock against any fraudulent attempts to cut away that portion of the bolt by which it is thrown, and thus delude the owner into fancying that he had secured his lock, when actually he had only turned the key round in the lock and lifted the levers without carrying the bolt to its destination. These two principles of protection against picking and against fraud are now combined in the 'patent protector locks,' manufactured by Hobbs, Hart, and Co. An important development of Hobbs' 'movable-stump' principle above referred to, is also the invention of J. M. Hart, and patented by him in 1865. Its main feature consists in the multiplication and combination of movable and fixed stumps to such a number that the whole length of a door secured by it would require to be broken away before the lock could be effectually violated.

A valuable and ingenious lock, containing still further principles of security was patented in 1851 by Robert Newall, of New York. It is popularly known as 'Hobbs' changeable lock,' having been introduced by him into this country. The principle on which it is constructed is that, by an admirable mechanical contrivance, the levers adjust themselves in the act of locking to any arrangement of the key-steps by which it is locked; and however the relative positions of the steps of the key may be changed, the levers take accurately a corresponding arrangement. By this means any person holding the key may vary it at pleasure, and thus virtually obtain a new lock as often as he pleases. This lock has since been considerably improved in the details of its construction, and, as now made, constitutes the highest attainment of mechanical art that has ever been reached in this department of industry and skill. Fig. 4 shows a complete lock of this description, with its key and movable bits.

Locks that are actuated without keys are known as puzzle or letter locks; they differ from any of the above, and afford certain advantages peculiar to this class of locks. They are made on the permutation principle, of which the simplest application is the padlock. These locks are regarded rather as an ingenious toy than as an available substitute of the more usually constructed locks. Fig. 5 represents this particular lock.

Some locks have been made in which the action depends on the key being a powerful magnet. In others the difficulty of opening is increased by requiring a peculiar method of applying the key; but in addition to the circumstance that the secret must be known to several persons, these advantages have

the disadvantage of being very inconvenient in use. Many contrivances have been effected for attaching an alarm to locks, by which the introduction of a false key should ring a bell or fire a pistol; but all such contrivances are curiosities rather than conveniences.

LOCK-JAW. [TETANUS.]

LOCK OF A CANAL. [CANAL.]

LOCKE, JOHN, was born at Wrington, near Bristol, on the 29th August, 1632. Locke was placed at Westminster School, from which he was elected in 1651 to Christ Church, Oxford. He applied himself at that university with great diligence to the study of classical literature, and by the private reading of the works of Bacon and Descartes sought to acquire that alimnet for his philosophical spirit which the Aristotelian scholastic philosophy, as taught in the schools of Oxford, did not afford. He adopted the profession of medicine, which, however, the weakness of his constitution prevented him from practising.

In 1664 Locke visited Berlin as secretary to Sir W. Swan, envoy to the elector of Brandenburg; but after a year he returned to Oxford, where he accidentally formed the acquaintance of Lord Ashley, afterwards earl of Shaftesbury, and accepted his invitation to reside in his house. Here he became acquainted with some of the most eminent men of the day, and was introduced to the earl of Northumberland, whom, in 1668, he accompanied on a tour into France. Upon the death of the earl, he returned to England, where he again found a home in the house of Lord Ashley, who was then chancellor of the exchequer, and Locke was employed to draw up a constitution for the government of Carolina, which province had been granted by Charles II. to Lord Ashley with seven others.

In 1672, when Ashley was created Earl of Shaftesbury and made lord chancellor, Locke was appointed secretary of presentations. This situation he held until Shaftesbury resigned the great seal, when he exchanged it for that of secretary to the Board of Trade, of which the earl was still president.

In 1674 Locke visited France, and resided at Montpelier. In 1679 he was recalled to England by the earl of Shaftesbury, who had been restored to favour and appointed president of the council. Six months afterwards, however, when the earl was again disgraced, and was ultimately compelled to leave England (1682) to avoid a prosecution for high treason, Locke followed him to Holland, where, even after his patron's death, he continued to reside; for the hostility of the court had been transferred to Locke, and his name was erased, by royal mandate of the 16th of November, 1684, from the number of the students of Christ Church. During his residence in Holland he had commenced his 'Essay concerning Human Understanding' in 1675, which he completed in 1687. On the revolution of 1688, Locke returned to England in the fleet which conveyed the princess of Orange. He now obtained through the interest of Lord Mordaunt, the situation of commissioner of appeals, with a salary of 200*l.* a year. In 1690 his reputation as a philosophical writer was established by the publication of his 'Essay concerning Human Understanding,' which met a warm reception. Numerous editions passed rapidly through the press, and translations were

made of it into Latin and French. In the same year Locke published two treatises on Government. These essays were intended generally to answer the partisans of the exiled king, who called the existing government a usurpation, but particularly to refute the principles advanced in the 'Patriarcha' of Sir Robert Filmer. In the second essay Locke maintains that the legitimacy of a government depends solely and ultimately on the popular sanction, or the consent of men making use of their reason to unite together into a society or societies. The philosophical basis of this treatise formed a model for the 'Contrat Social' of Rousseau, the source of great errors and infinite miseries to mankind.

The air of London disagreeing with Locke, he accepted the offer of apartments in the house of his friend Sir Francis Masham, at Oates in Essex. In this retirement he wrote a third letter on Toleration, which called forth a reply from a former antagonist of Locke on the subject; in answer to whom a fourth letter, in an unfinished state, was published after its author's death. In 1693 he first gave to the world his 'Thoughts upon Education,' to which Rousseau has been largely indebted for his 'Emile.' Though appointed one of the commissioners of trade and plantations in 1695, he still found leisure for composition; and he was principally engaged in writing on Christianity.

His health had now become so impaired that he resigned his office of commissioner of trade and plantations, refusing a pension which was offered him. From the time of his retirement he resided at Oates, and devoted the remainder of his life to the study of the Holy Scriptures. He died on the 28th of October, 1704, in the seventy-third year of his age.

The personal character of Locke was in complete harmony with the opinions which he so zealously and so ably advocated. Truly attached to the cause of liberty, he was also willing to suffer for it. Perfectly disinterested, and without any personal object at stake in the political views which he adopted, he never deviated from moderation; and the sincerity of his own profession rendered him tolerant of what he believed to be the conscientious sentiments of others.

Locke has a happy facility in expressing his meaning with perspicuity in the simplest and most familiar language. Clearness, indeed, is the leading character of his composition, which is a fair specimen of the best prose of the period. His style, however, is rather diffuse than precise, the same thought being presented under a great variety of aspects, while his reasonings are somewhat prolix, and his elucidations of a principle occasionally unnecessarily prolonged. These are faults, however, which, though they may materially detract from the merits of his composition as a model of critical correctness, have nevertheless greatly tended to make his 'Essay concerning Human Understanding' a popular work.

LOCKERBIE. [DUMFRIESSHIRE.]

LOCKFAST PLACES. The opening of lockfast places is, in Scotch law, an aggravation of the crime of THEFT.

LOCKHART, JOHN GIBSON, D.C.L., was born at Cambusnethan, in Lanark, in 1794, and educated at Glasgow. Such was his early progress in scholastic studies, that in 1809, at the early age of fifteen, he received the Snell exhibition to Balliol

College, Oxford. He there graduated as B.C.L. in 1817; and in 1834 had the diploma of D.C.L. conferred upon him. After visiting the Continent he was called to the Scottish bar in 1816, but never distinguished himself in forensic eloquence. In 1818 he became acquainted with Sir Walter Scott, who recommended him to the publishing firm of the Ballantynes, and he was employed to write the historical part of the *Edinburgh Annual Register*. Lockhart now became a most intimate friend of Professor Wilson, and his ablest coadjutor in the conduct of *Blackwood's Magazine*. In 1820 he was married to Sophia, the eldest daughter of Sir Walter Scott, and lived for some time at Chiefswood, a cottage within an easy distance of Abbotsford. In 1821 he published his first novel, entitled 'Valerius, a Roman Story,' which was soon followed by 'Reginald Dalton,' 'Adam Blair,' 'Ancient Spanish Ballads,' and 'History of Matthew Wald.' In 1825 his 'Life of Burns' made its appearance, and he also wrote a 'Life of Napoleon.' In 1826, on the death of Mr. Gifford, Lockhart was appointed editor of the *Quarterly Review*, which he conducted with great learning and ability for a period of twenty-eight years.

On the death of Sir Walter Scott, in 1832, Lockhart was selected as his biographer; and he executed his important trust with equal skill and discretion.

In 1843 Sir Robert Peel appointed him to the office of auditor of the duchy of Cornwall, at a salary of 600*l.* per annum. In 1853 his declining health compelled him to resign the editorship of the *Quarterly Review*; and with broken spirits he visited Rome, but without any benefit to his enfeebled system. On his return to Scotland he was able to rally in some degree; but a violent attack of diarrhoea, acting upon a weakened constitution, speedily terminated his existence in November, 1854.

Some interesting details of his character and genius will be found in Mrs. Gordon's 'Life of Professor Wilson.'

LOCMARIA. [BELLE-ILE-EN-MER.]

LOCOMOTIVE STEAM ENGINE, or LOCOMOTIVE, a machine consisting essentially of a carriage, on which are conveyed a steam boiler and a steam engine; the engine serving to drive one or more of the wheels of the carriage, so as to enable it to move from place to place, and also to propel other carriages, usually by dragging, and sometimes by pushing. The stores of fuel and water may be carried either by the locomotive itself, or by a separate carriage called a *tender*. Locomotives are used chiefly on railways, and occasionally on common roads. The application of the steam engine to locomotion on land was, according to Watt, suggested by Robison in 1759. The first actual locomotive engine appears to have been a steam carriage for use on common roads, invented by Cugnot, a French engineer, about 1763. It was made, and tried upon a short journey, in 1769, and in an improved form in 1770; but was abandoned on the ground of supposed danger. In 1769 and 1784 Watt took patents for the application of his steam engine to locomotion; but those inventions were never carried into effect. In 1784 William Murdoch, assistant to Watt, made a very efficient working model of a locomotive engine. The first practically successful locomotive engine was that of Trevithick and Vivian, patented in 1802, and

set to work in 1804. It travelled at about 5 miles an hour, with a net load of ten tons, on a tramway near Merthyr Tydvil.

After various inventors had long exerted their ingenuity in vain to give the locomotive engine a firm hold of the track by means of roughened wheel-tires, rackwork-rails, and toothed driving wheels, legs and feet, and other contrivances, William Hedley, in 1813, made the important discovery that no such aids are required, the adhesion between smooth wheels and smooth rails being sufficient. To adapt the locomotive engine to the great and widely varied speeds at which it now has to travel, and the varied loads which it now has to draw, two things are essential—that the rate of combustion of the fuel, the original source of the power of the engine, shall adjust itself to the work which the engine has to perform, and shall when required be capable of being increased to many times the rate at which fuel is burned in the furnace of a stationary engine of the same size; and that the surface through which heat is communicated from the burning fuel to the water shall be very large compared with the bulk of the boiler. The first of those objects is attained by the *blast-pipe*, invented and used by George Stephenson in 1814; the second, by the tubular boiler, invented about 1829, simultaneously by Séguin in France and Booth in England, and by the latter suggested to Stephenson, who was the first to combine those inventions, and adapt them to a form of engine and arrangement of mechanism suited to high speeds. On the 6th October, 1829, occurred that famous trial of locomotive engines, when the prize offered by the directors of the Liverpool and Manchester Railway was gained by Stephenson's engine the *Rocket*, the parent of the swift and powerful locomotives of the present day. The *Rocket*, and two of the other engines which competed on that occasion, Hackworth's *Sanspareil*, and Braithwaite and Ericsson's *Novelty*, are preserved in the Patent Office Museum at South Kensington. Since that time the locomotive engine has been varied and improved in various details, and by various engineers. Its weight now ranges from 5 tons to 60 tons; its load from 50 to 500 tons; its speed from 10 miles to 70 miles an hour.

The hauling force of a locomotive engine is in general limited, not by the power which the engine is capable of exerting—for that is almost always more than sufficient to draw any load that it ever has to convey—but by the '*adhesion*,' as it is called, or force which prevents the driving wheels from slipping on the rails.

The adhesion is equal to the weight which rests on the driving wheels, multiplied by a coefficient which depends on the condition of the surface of the rails; being greatest when they are clean and dry, and least when they are wet and greasy, or covered with ice.

On an average, the adhesion of a locomotive engine may be estimated at about one-seventh of the load on the driving wheels; for by sprinkling sand on the rails when they are slimy, or if they are icy, directing jets of steam on them, it may in general be prevented from falling below that amount.

In order that the rails may be able to bear the load on the driving wheels without damage, it is considered advisable that the load on *each wheel* should not in ordinary cases exceed 1 ton for every 15 lbs.

in the weight of a yard of rail; that is to say, for rails of the ordinary weight of 75 lbs. to the yard 5 tons = 11,200 lbs. Nevertheless there are examples of heavy engines in which the load on each driving wheel is 7 tons.

Locomotive engines are seldom made with fewer than six wheels. Those which are intended for the propulsion of comparatively light trains at high speeds have but one pair of driving wheels of from 5 feet 6 inches to 7 feet 6 inches, and sometimes even 8 feet in diameter. The best position for the shaft of that pair of wheels is nearly under the centre of gravity of the engine, in which case, by proper adjustment of the springs, it can be made to bear any proportion of the weight from $\frac{1}{3}$ to $\frac{2}{3}$. Engines for goods trains of moderate weight have also usually six wheels, two pairs of which are driving wheels, of 5 feet diameter, and are coupled together. For heavier goods and mineral trains engines are used having all six wheels coupled, and usually of smaller diameter, such as 4 $\frac{1}{2}$ or 4 feet, and in some cases of engines for ascending steep inclined planes, 3 $\frac{1}{2}$ or 3 feet; and occasionally the wheels of the tender also are driven by steam power.

WEIGHTS OF ENGINES WITH SEPARATE TENDERS.

(The Tender weighs from 10 to 15 tons.)

	Tons.
Narrow gauge passenger locomotives, six-wheeled, with one pair of driving wheels, ...	19 to 23
Do. do. do. unusually heavy, ...	24 to 27
Broad gauge passenger locomotive, eight-wheeled, with one pair of driving wheels	35
8 feet in diameter, ...	
Goods locomotive, from four to six wheels, coupled, ...	27 to 32

WEIGHTS OF TANK ENGINES, CARRYING FUEL AND WATER.

	Tons.
For light traffic on branch lines, ...	12 to 20
For heavy traffic on steep inclined planes, with from 6 to 12 wheels, ...	40 to 60

By an invention of Mr. Ramsbottom, the tender of a locomotive is made to supply itself with water while in motion, through a tubular scoop which dips into a long water-trough lying between the rails. The speed should be at least 22 miles an hour, to enable the apparatus to work. (See Plate 3, fig. 1.)

In comparing the tractive force of a locomotive engine, as limited by adhesion, with the resistance and gravity of the train which it is to draw, it is obvious that the resistance due to friction and concussion of the engine itself is to be left out of account; for that resistance does not constitute a backward pull on the engine, tending to make the driving wheels slip.

It appears, then, that the *available tractive force* of a locomotive engine in ascending a given inclined plane, which must be at least equal to the resistance of the heaviest train that it has to draw, is to be found by subtracting from the adhesion that component of the weight of the engine which acts as a resistance to its ascent; that is to say, the weight of the engine, divided by the number of times that the length of the inclined plane contains the height of the ascent.

The resistance of the load dragged behind the engine, which must not be greater than the adhesion of the engine, is made up of the resistance on a level, and of the resistance due to gravity. The resistance due to gravity is found, as in the case of the engine, by dividing the load by the number of times that the

length of the inclined plane contains the height of ascent. The resistance on a level is made up of three parts, due respectively to friction, to concussion, and to curvature. The resistance due to friction ranges from '0027 to '004 of the load, according to circumstances. The resistance due to concussion at a speed of 12 miles an hour is about one-tenth of the resistance due to friction; and at other speeds it varies as the square of the speed. The resistance due to curvature, on a curve of 1000 feet radius, is about '0033 of the load; and of other radii it varies inversely as the radius.

Besides drawing the train, the locomotive engine has to overcome the resistance of its own wheels and axles, and of its own mechanism. If the mechanical energy thus expended, while the engine travels a given distance, be divided by that distance, there is obtained the additional train-resistance which would be equivalent to the resistance of the engine; and this being added to the resistance of the tender and train, gives the *gross resistance* of the engine, tender, and train.

The resistance of the engine consists of two parts; the first, being the resistance of the engine *as a carriage*, is the same with that of a train of the same weight; the second, being the resistance caused by the strain on the mechanism, bears a certain proportion to the whole resistance of the engine and train, whether arising from friction, concussion, curvature, or gravity; and that proportion appears to be about one-third. Hence, to calculate the *gross effort* of a locomotive engine, take the sum of the resistances due to friction, concussion, curvature, and gravity, for the *gross load* and to that sum add *one-third*.

The *energy exerted by the engine per minute*, in foot-pounds, is the product of the effort or gross resistance in pounds and speed in feet per minute. To find the *mean effective pressure* of steam in the cylinders, divide the energy exerted per minute by the volume swept by the pistons per minute; if that volume is expressed in cubic feet, the quotient will be the required pressure in lbs. on the square foot, which divided by 144 will give lbs. on the square inch. The *indicated horse-power* of the engine is found by dividing the energy exerted in foot-pounds per minute by 33,000.

The following are some examples of the results of such calculations; the line of railway being supposed straight, and the rails and rolling stock in a good condition, so that the resistance due to friction is only '0027 of the load:—

EXAMPLE.	I.	II.	III.
1. Speed in miles an hour, ...	24	18	12
2. Ascending gradient, ...	1 in 133'3	1 in 133'3	1 in 80
3. Weight of engine, ...	20 tons	30 tons	30 tons
4. Weight of tender, ...	10 "	12 "	15 "
5. Weight of train, ...	104 "	245 "	238 "
6. Effort or gross resistance, ...	4502 lbs.	9241 lbs.	13,057 lbs.
7. Circumference of driving wheel, ...	20 feet	15 feet	14 feet
8. Stroke of pistons (2 in number), ...	2 "	2 "	2 ft. 2 in.
9. Area of each piston, ...	200 sq. in.	226 sq. in.	253 sq. in.
10. Mean speed of pistons, feet per minute, ...	422'4	422'4	328'85
11. Volume swept through by pistons in cubic feet per minute, ...	1173'3	1325'9	1155'58
12. Mean effective pressure in lbs. on the square inch, ...	56'3 lbs.	76'7 lbs.	83'4 lbs.
13. Indicated horse-power, ...	228	444	418

The pressure of the steam in the boiler exceeds the mean effective pressure in the cylinder in a proportion depending on the extent to which the steam is worked expansively, and various other circumstances. It usually ranges in practice from 80 lbs. to 140 lbs. per square inch above the atmospheric pressure. In some cases engines have been worked at a pressure of 200 lbs. per square inch. The most common pressures at present are from 100 to 120 lbs.

The speed at which the engine runs when exerting a given effort is regulated by the quantity of steam at the required pressure which the boiler is capable of producing; which quantity depends on the quantity of fuel that can be burned in the furnace in a given time, and the efficiency of that fuel in producing steam.

The consumption of fuel by locomotive engines, per indicated horse-power per hour, may be estimated as ranging from 3 to 5 lbs., and the evaporation from 7 to 9 lbs. per lb. of fuel. The whole area of heating surface in ordinary engines varies from 800 to 2000 square feet; and the area of heating surface for each lb. of fuel burned per hour varies from about half a square foot to 1½ square foot, and is on an average about one square foot.

The action of the blast-pipe gives to the locomotive engine the power of adapting its consumption of fuel to the work which it has to perform, within certain limits. Hence the rapid consumption of fuel by heavy and powerful engines, in ascending steep inclined planes, is to a great extent compensated by the saving which takes place in descending.

The details of the construction of locomotive engines, and of the action of the fuel and steam in them, cannot be comprehended in the present article. For information respecting these matters, see Mr. D. K. Clark's work 'On Railway Machinery,' Mr. Z. Colburn's work 'On Locomotive Engineering,' and that of Professor Rankine on 'The Steam Engine and other Prime Movers.'

Both engines and carriages may be adapted to sharply curved lines of railway by means of the 'bogey,' a truck capable of turning about a pivot into various positions relatively to the carriage or engine which it supports. A locomotive engine has a two-wheeled bogey under the leading end, the after end being supported on one or two pairs of driving wheels, and the pivot about which the bogey turns being midway between the centre of the bogey and the middle point between the axles of the driving wheels. Instead of a bogey and pivot, Mr. W. B. Adams uses a pair of axle-boxes for the leading wheels, sliding in curved guides, whose centre is at the point already described as the proper place for the pivot. By the aid of these contrivances engines and carriages are enabled to pass round curves of radii as small as 3½ chains (231 feet). On British railways curves of sharper radii than 10 chains are of rare occurrence. For the purpose of ascending gradients on which the ordinary adhesion would be insufficient, locomotives have been introduced in which the engine drives a pair of small horizontal wheels, which grip between them a central rail with a force that can be adjusted so as to prevent slipping.

Locomotive engines for common roads fell for many years into disuse; but have been revived in the 'traction engine.' This machine, of which various

forms have been invented, is adapted to drawing long trains of heavily laden vehicles at a low speed, such as four or five miles an hour, and appears to have been quite successful. To insure that the driving wheel shall take a sufficient hold of the road, without injuring its surface, different contrivances are used; for instance, in one form of traction engine the driving wheel successively sets down in front of itself, runs over, and picks up again, a series of flat oblong plates or shoes, which form a sort of endless tramway for the wheel to run upon, and enable it not merely to travel on roads, but on rough and soft ground.

The examples of railway locomotives in the following illustrations are taken mainly from those shown at the London International Exhibition of 1862.

Plate 4 is a longitudinal section, and Plate 5 a transverse section of an engine by John Ramsbottom, Esq., being one out of a great number of similar engines now used on the London and North-Western Railway. The driving wheels are 7 feet 7½ inches in diameter, the wheel base is 15 feet 5 inches; the cylinders are outside, and are 16 inches diameter and 24 inches stroke; the area of the fire grate is 14·95 square feet; of fire-box heating surface 85 square feet; of external tube surface 1013 square feet. The boiler is fed without pumps by two Giffard's injectors, and is fitted with Mr. Ramsbottom's duplex safety valve, in which a pair of valves are pressed down by the two ends of a cross-bar, the middle of which is held down by means of a spring, as shown in the Plate—an arrangement which makes it impossible for the engine-driver to increase the load on the valves. The ordinary working pressure is 120 pounds on the square inch.

Plate 2, fig. 2, represents a sectional elevation of an express engine, made by Messrs. Neilson and Company, of Glasgow, for the Caledonian Railway Company, according to the design of Benjamin Conner, Esq., locomotive superintendent. Its driving wheels are of the great diameter of 8 feet 2 inches; the wheel base is 15 feet 8 inches; the trailing axles have outside journals; the cylinders are outside, and are of 17¼ inches diameter, and 24 inches stroke; the area of fire-box surface is 96 square feet; of external tube surface 1094 square feet. The weight of the engine when in working order is 30 tons 13 cwt., and of this the unusually large proportion of 14 tons 11 cwt. rests on the driving wheels.

Plate 1, fig. 2, represents an express passenger engine, belonging to the Imperial and Royal Austrian State Railway Company, and designed by John Haswell, Esq., the manager of their engineering works. The driving wheels are 6·74 feet in diameter, and are placed to the rear of the other two pairs of wheels; the bearings are outside; the wheel base, for the purpose of passing easily round curves, is short, being about 11 feet; the cylinders are outside, and are four in number, of 11 inches in diameter, and 25 inches stroke; the area of fire-grate is 15 square feet, of fire-box surface 84 square feet, of tube surface 1260 square feet. The engine when in working order weighs 32 tons, of which about 12½ tons rest on the driving wheels. Each end of the axle is driven by a pair of cylinders lying side by side, in which the pistons move in opposite directions, and thus a balance of inertia is effected of a much more perfect kind

than can be obtained by any system of revolving counterpoises. The compound cranks, which are exposed to a somewhat severe and complex strain, are made of Krupp's cast steel. This engine has run at a speed of 14 German miles, or nearly 70 British miles per hour. (For details see 'Mittheilungen über die zur Londoner Ausstellung im Jahre 1862, von der k. k. priv. (Österr. Staats-Eisenbahn-Gesellschaft gesendeten Gegenstände.')

Plate 2, fig. 3, represents a coal-burning heavy goods engine, made for the London, Chatham, and Dover Railway, by Messrs. Sharp, Stewart, and Company. The wheels are 5 feet in diameter; the wheel base 15½ feet; the cylinders are inside, of 17 inches diameter, and 24 inches stroke; the area of fire-grate is unusually large, being 27½ square feet; the fire-box surface is also large, being 120½ square feet; the tube surface is 1063 square feet; the boiler is fed by a pair of Giffard's injectors, without pumps. The weight of the engine is when empty 28 tons 11½ cwt.; when full 32 tons 1 cwt.

The coal-burning arrangement is Mr. Cudworth's. The grate is very long, measuring 7 feet 3¼ inches in length; it slopes downwards from the door towards the front, and is divided longitudinally by a partition or 'mid-feather;' and smoke is prevented by alternate firing, and by letting the gas distil from the coal near the fire doors before pushing the fuel forward.

Plate 2, fig. 1, is an elevation of a ten-wheeled engine belonging to the Imperial and Royal Austrian State Railway Company, at whose works it was made, under the direction of Mr. Haswell. It has a jointed carriage to enable it to pass round curves. The fore-carriage, which supports the mechanism and the front part of the boiler, has six wheels 3 feet 4 inches in diameter, with a wheel base of 7 feet 4 inches. The after-carriage, which supports the coal-box, the tank, and the fire-box end of the boiler, has four wheels, 3 feet 4 inches in diameter, with a wheel base of 7 feet 4 inches; the mean distance from the hind axle of the fore-carriage to the front axle of the after-carriage is 4 feet 9 inches; giving a mean total wheel base of 19 feet 5 inches. The bearings are outside the wheels; the cylinders are outside the bearings, and are of 18½ inches diameter and 25 inches stroke; the slide-valve gear is inside the wheels.

The wheels are cast-iron discs, with cast-steel tires.

The tank, which is in two divisions, one at each side of the fire-box, holds about 5 tons of water; the coal-box about 2 tons of fuel.

The grate measures somewhat more than 15 square feet in area; the fire-box surface is about 80 square feet, the tube surface about 1260 square feet.

The boiler frame rests on the after-carriage by means of slides, which allow of sufficient change of position in going round curves.

The engine weighs when full about 42 tons.

It has been proved by experience to be capable of drawing 200 tons up an ascent of 1 in 40, with curves of 300 feet radius, at an average speed of about 10 miles an hour.

The most remarkable feature of this engine is the mechanism whereby motion is communicated from the wheels of the fore-carriage (which are directly driven by the engine) to those of the after-carriage, notwithstanding the joint between them, and their

relatively oblique position while the engine passes round curves.

In the following description the hind axle of the fore-carriage will be called 'the third axle,' and the fore axle of the after-carriage 'the fourth axle.'

About two feet directly above the fourth axle is an axle which may be called 'the intermediate axle.' It is supported upon the fourth axle by two uprights, whose bearings are ball and socket joints, so that they admit of those axles becoming oblique to each other horizontally.

The intermediate axle is kept exactly parallel to the third axle by means of a pair of sloping rods.

Each of those three axles has a pair of cranks on its ends, at right angles to each other. The cranks of the intermediate axle are connected with those of the third axle, and also with those of the fourth axle, by means of four connecting rods, all of which have ball and socket joints; and thus a uniform rotation is communicated from the wheels of the fore-carriage to those of the hind-carriage in all their relative positions.

Full details of the theory and construction of this coupling are given in the publication formerly referred to, 'Mittheilungen,' &c.

Plate 1, fig. 3, represents a passenger engine, by Messrs. Ernest Gouin and Company, which has two pairs of cylinders, each pair of cylinders driving its own independent pair of wheels; so that the engine is like two ordinary engines fixed together end to end, with a single boiler of great size.

There are four driving wheels, two on each of the endmost axles, of 5 feet 3 inches in diameter; and six small intermediate wheels. The comparatively small size of the driving wheels has been adopted for the sake of lightness and cheapness; it is made compatible with a high speed by giving a sufficiently rapid stroke to the pistons.

In a goods engine of the same class there are twelve wheels, forming two sets of six coupled wheels, $3\frac{1}{2}$ feet in diameter.

The bearings are all inside, the cylinders and mechanism outside. The two slide-valve motions are acted upon by one reversing handle; but there are two independent regulators. The power of going round curves is provided for by giving end-play to the axles.

The following table gives the rest of the principal dimensions:—

	Passenger Engine.	Goods Engine.
Diameter of cylinders,	14·2 inches ...	16·5 inches
Stroke,	13·4 " ...	17·3 "
Area of grate, ...	28 sq. feet ...	36 sq. feet
Fire-box surface, ...	108 " ...	108 "
Tube surface, ...	1557 " ...	2034 "
Surface of steam-drying tubes, ...	129 " ...	154 "
Contents of water-tank, ...	7 tons ...	8 tons
coal-box, ...	2 " ...	2½ "
Weight of engine, empty, ...	35 " ...	41 "
full, ...	47½ " ...	56½ "
Load on driving wheels, ...	21 " ...	56½ "
engine full, ...		
Working pressure about 120 lbs. on the square inch.		

Plate 1, fig. 1, represents a small locomotive for the use of contractors, &c. Its leading dimensions are as follows:—Diameter of wheels, 2 feet 9 inches; cylinders, outside, 9 inches diameter, 14 inches stroke; tank holds 250 gallons; weight of

engine, full, $10\frac{1}{4}$ tons. It can be adapted to any gauge from 3 feet upwards. Working pressure, 120 lbs. on the square inch.

LOCUS was a name employed to designate the country of three distinct Grecian tribes, the Locri Epionemidii, the Locri Opuntii, and the Locri O'zolæ.

The Locri Epionemidii and Locri Opuntii inhabited the eastern coast of Phocis, and were separated from the latter country by a mountain range which stretches from Mount Œta to the borders of Bœotia. The northern part of this range was called Cnemis, whence the Epionemidii Locri derived their name. The Opuntii Locri derived their name from Opus, their chief town on the borders of Bœotia.

The Locri Ozolæ were bounded on the west by Ætolia, on the north by Doris, on the east by Phocis, and on the south by the Corinthian Gulf. The principal towns of western Locris were Amphissa, now Salona, at the head of the Crissæan Gulf, and Naupactus, now Lepanto.

The Locri Epizephyrii, or Western Locri, who inhabited the south-eastern extremity of Italy, were a colony, according to Ephorus, of the Locri Opuntii, but according to Strabo, of the Locri Ozolæ. The Locri Epizephyrii are said to have been the first Greek people who had a written code of laws, which was drawn up by Zaleucus about B.C. 664.

LOCUS. This word, or the Greek τόπος, signifying simply 'place,' was used by the first geometers to denote a line or surface over which a point may travel, so as always to be in a position which satisfies some given condition. Thus, suppose it required to find the position of a point at which a given line subtends a right angle: the answer is, that the number of such points is infinite; for that any point whatsoever upon the surface of a sphere which has the given line for its diameter is such a point as was required to be found. This would be expressed as follows:—The locus of the point at which a given line subtends a right angle is the sphere described on the given line as a diameter. If, however, the point were required to be in a given plane, its locus would no longer be the whole sphere, but only that circle which is the common section of the sphere and the given plane.

LOCUS PŒNITENTIÆ, in Scotch law, is the power of drawing back from a bargain, and is competent to either party so long as the transaction is incomplete in law.

LOCUST (the *Gryllus migratorius* of Linnæus, *Locusta migratoria* of modern entomologists), a well-known insect, belonging to the order *Orthoptera*, section *Saltatoria*, and family *Locustidæ*. Locusts are endowed with great strength for leaping and flying, and being gregarious, are thus able to commit great devastation, for, when a swarm has destroyed the vegetation of one district, they are enabled to take flight to and traverse another, even though at a considerable distance. The migratory locust has occasionally visited England. In Southern Europe, the East, and Northern Africa, this species and its allies are exceedingly destructive, the swarms being so vast as to destroy all vegetation, whilst the putrefying carcasses of their dead infect the air. The Arabs and people of Nigritia use these insects as food.

Besides the genus *Locusta*, the following are contained in the family *Locustidæ*, viz.: *Gomphocerus*, *Acrydium*, *Pneumora*, and *Proscopia*.

The other families of the *Saltatoria* are *Achetidae* (examples, the Mole-cricket and the House-cricket) and *Gryllidae* (example, the Great Green Grasshopper, *Acrida viridissima*).

LOCUST TREE is the *Robenia pseudacacia* of botanists, a North American forest tree. The same name has also been given to the *Ceratonia siliqua*, or Carob Tree.

LODDON. [BERKSHIRE.]

LODE, a term used by miners for the *veins* in which minerals occur. They are crevices produced by contraction, or the mechanical disturbance of the rock, and which have subsequently been filled with metallic ores.

LODÈVE. [HÉRAULT.]

LODGE, THOMAS, is supposed to have been born about 1556. He was entered at Trinity College, Oxford, in 1573, took a degree, and then, going to London, became an actor and dramatist. About 1580, in an answer to Gosson's 'School of Abuse,' he wrote a 'Defence of Stage-plays,' which being suppressed by authority only two copies of it exist. His 'Alarum against Usurers' was printed in 1584. In the same year he was a student of Lincoln's Inn. Afterwards, it has been conjectured, he became a soldier. He accompanied the expeditions of Clarke and Cavendish. He is usually identified with a Doctor Lodge who took his degree in medicine at Avignon, and printed in 1603 'A Treatise on the Plague,' and in 1614 a translation of the 'Works of Lucius Annæus Seneca.' He is believed to have died of the plague in 1625.

He was a voluminous and versatile writer of novels, volumes of verses, and miscellaneous pamphlets; and a distinguished contributor to the drama in the years immediately preceding the appearance of Shakspeare. One of his novels is entitled 'Rosalynde, Euphues' Golden Legacie; found after his death in his cell at Silixedra,' 1590, 4to; reprinted in Mr. Collier's 'Shakspeare's Library,' 1840. From this novel Shakspeare borrowed the grouping of the characters, and many of the strokes of portraiture, for his 'As You Like It.'

LODGING-MONEY, in the British army, is an allowance in lieu of quarters, granted to officers, non-commissioned officers, and privates, when suitable rooms cannot be spared in the barracks. Married sergeants and privates receive eight shillings a week for lodging-money when on duty and not provided for in barracks. The charge for lodging-money in the army estimates for 1865-66 is 87,000*l*.

LODGINGS, THE LAW OF, differs according to the custom which regulates each particular case from the general rules of law between landlord and tenant.

As the length of the term for which lodgings are let seldom exceeds or even extends to a year, it is rarely the case that a six months' notice to quit is necessary. This can only happen when the tenancy is from year to year. But if the taking be for less than a year, as for a quarter, a month, or a week, which may be presumed from the rent being paid at the lapse of those terms, or other circumstances, the length of notice will be regulated accordingly, as a month for a month, and a week for a week, the expiration of the notice being that of the term. Unless the lodger gives up possession and pays the rent for

a whole term in advance, notice must always be given, and he will not be released from such a necessity merely from an apprehension, however just, of his goods being distrained for his landlord's rent.

The 24 and 25 Vict. c. 96, provides that if any tenant or lodger steal any fixture or chattel let to him, he shall upon being convicted be liable to be imprisoned for two years, with or without hard labour; and if the value of the article stolen exceed 5*l*., to be kept in penal servitude for not less than three or more than seven years.

LODI-E-CREMA, a province of Italy, is bounded N. by the Milanese and Bergamo, W. by Pavia, S. by the Po, which divides it from Parma and Piacenza, and E. by Cremona and Brescia. The province is part of the great plain of the Po, and is watered by the Adda, Serio, Lambro, and other affluents of that river. Until the end of the last century this province was divided into two small ones, which were separated by the Adda, namely, Crema to the east of that river, which then belonged to the republic of Venice, and Lodi, west of the Adda, which was part of the ancient duchy of Milan.

The length of the province is 30 miles from E. to W., and above 27 miles from N. to S. The area is 247 geographical square miles, and the population 240,000. The soil is partly sown with corn, flax, and pulse, and partly planted with the vine and mulberry trees; but the best part consists of artificial meadows, rendered productive by irrigation. On these are fed a great number of cows, from whose milk the rich cheese is made known in Lombardy by the name of Lodigiano, but called, by an odd misnomer, in the rest of Europe Parmesan. Great attention is paid to the rearing of silkworms, and a good deal of coarse raw silk is brought to market. Linen and cordage are also manufactured. A considerable number of horses and pigs are bred.

Lodi, the capital of the province, is a well-built episcopal town, on the right bank of the Adda, with in 1861 19,562 inhabitants. Lodi has a royal lyceum and a gymnasium, a theological seminary, an orphan asylum, two hospitals, the Barni and Martini palaces, a savings' bank, a public library of 15,000 volumes, and a Monte-di-Pietà. The most interesting structures in Lodi are the church of L'Incoronata, and the stone bridge over the Adda, famous for the defeat of the Austrians by Bonaparte on the 10th of May, 1796.

Crema, an episcopal town on the right bank of the Serio, is a well built place, with a gymnasium and 8000 inhabitants, who manufacture linen and linen thread. Codogno, S.E. of Lodi, is a flourishing town with 10,000 inhabitants, a theatre, and a considerable trade in cheese, silk, &c. San-Colombano, at the foot of a hill near the right bank of the Lambro, has a population of 6844.

LOFODEN ISLANDS. [TRONDHIEM.]

LOG and LOG'LINE, the apparatus by which the velocity of a ship's motion through the water is measured. The log is a flat piece of wood, loaded with lead at one of its edges to make it float upright; and to this is attached a line about 150 fathoms long, divided into equal lengths by little pieces of knotted twine rove into it. These divisions begin about twenty or thirty yards from the log, where a piece of red rag is usually fastened, in order to show

the place readily. From the lee quarter of the vessel the log is thrown into the sea, where it is supposed to remain stationary during the operation, and the line is veered out at least as fast as the ship sails. As soon as the red rag leaves the reel a half-minute glass is turned, and when the sand is all run down the reel is stopped. Then by measuring the quantity of line run out, the distance sailed by the vessel in half a minute is known, and by calculation its rate of going per hour. The usual way of dividing the line is to place the knots at distances of fifty feet from each other. Now, as 120 times half a minute make an hour, and 120 times fifty feet make almost a geographical mile, so many knots will run from the reel in one experiment as the vessel sails miles in the hour; from this comes the expression of a vessel's sailing so many knots an hour, meaning miles.

Of late years Massey's patent log has been much used, with great benefit to navigation. It may be allowed to tow astern for hours, and the speed of the ship during the interval is accurately noted on a self-registering dial.

LOG-BOARD and LOG-BOOK. The former is either a large piece of plank, blackened, ruled, and prepared for writing on with chalk, or else a slate with divisions scratched upon its surface; and the latter is the blank book, in which are inserted daily the contents of the board: these are, the course of the vessel, the direction of the wind, and the distance run, as given by the log: in the book is also inserted a record of the different events which occur during the voyage.

The place of the ship, thus obtained by the log and compass, is technically termed *Dead Reckoning*; and this is used until an opportunity is afforded of taking observations for latitude and longitude, or until some place whose position is known comes in sight; the true place of the ship is then substituted in the log-book for that obtained by dead reckoning, and from that place subsequent reckonings are made until another observation is obtained.

By the 17 & 18 Vict. c. 104, the Board of Trade sanctions certain forms of log-books (called *official logs*), as adapted to particular voyages, and it is rendered imperative on every commander to see that all the entries be made as soon as possible after the occurrences happen which are obliged to be noted. It is also compulsory upon every master of a vessel to produce the log-book for the inspection of any ship of war of his own nation whose captain may require its production.

LOGAN, JOHN, born at Fala, in the county of Edinburgh, in 1748, was the son of a small farmer. Being destined to the clerical profession, he was educated in the University of Edinburgh, and became one of the ministers of Leith. In 1770 he had edited the posthumous poems of his friend Michael Bruce, incorporating with them some pieces which he claimed (and probably justly) as his own, and among which was the well-known 'Ode to the Cuckoo.' In 1779 he delivered in Edinburgh a course of lectures on the 'Philosophy of History.' In 1783 he printed, and caused to be acted in Edinburgh, a tragedy called 'Runnimede,' which had been rehearsed at Covent Garden, but was refused a license by the lord chamberlain. This publication brought on him the anger of the Presbyterians; and these

and other annoyances induced him in 1785 to quit his parochial charge and repair to London. There he eked out his livelihood by literary labour, and died December 28, 1788.

LOGANIA/CEE (from *Logania*, one of the genera, so called in honour of James Logan), in Botany, an order of Dichlamydeous exogens, consisting of herbs, shrubs, and trees, with opposite leaves entire, and generally stipulate. The order consists of 22 genera, and about 160 species.

LOGARITHMS. The etymology of this word is *λογῶν ἀριθμός*, 'the number of the ratios.'

The early history of logarithms will be found at length in the preface to Dr. Hutton's Tables; in the 'History of Logarithms' contained in the first volume of Dr. Hutton's 'Tracts'; in Delambre's 'Histoire de l'Astronomie Moderne,' vol. i. pp. 491-568.

The idea of logarithms originally arose (in the mind of John Napier, of Merchistoun, in Scotland) from the desire to make addition and subtraction supply the place of multiplication and division. A table, in which are registered 1, a , a^2 , a^3 , &c., supplies this desideratum to a certain extent; for, since a^x multiplied by a^y gives a^{x+y} , we find the product of the first two by adding their exponents, and looking in the table for the $(x+y)$ th power. Thus, for the set, 1, 2, 4, 8, 16, &c., a table of logarithms is easily constructed, a specimen of which is as follows:—

Num.	log.	Num.	log.	Num.	log.
1	0	32	5	1024	10
2	1	64	6	2048	11
4	2	128	7	4096	12
8	3	256	8	8192	13
16	4	512	9	16384	14

Thus, to multiply 64 and 128, that is, to find the product of the sixth and seventh powers of 2, we must take the $(6+7)$ th or 13th power, which, from the table, is 8192.

Such a table would be useless for general purposes, since it omits more numbers than it contains. But if we take a very little greater than unity, the powers will increase but slowly, and every whole number within given limits may be made either a power of a , or very near to a power of a . Suppose, for instance, that we wish for a table of logarithms which shall contain among its numbers either every whole number under a million, or a fraction within h of every number under a million. Extract the square root of one million, the square root of that square root, and so on, until the r th root of one million has been extracted, and let this r th root be $1+t$. It is obvious that this extraction may be carried on until t is as small as we please. Consequently $(1+t)^r$ is a million, and every lower power of $1+t$ is less than a million, so that (m standing for a million) no two consecutive powers differ by so much as the difference of m and $m(1+t)$, or by so much as mt . If, then, we proceed with the extraction until mt is less than h , we shall have t of the degree of smallness required: that is, since every whole number less than m lies between two powers of $1+t$, having exponents less than r , *à fortiori* every such whole number must be within h of some power of $1+t$.

This is, in fact, the first view which was taken of the method of constructing tables of logarithms; and

it must be remembered that Napier was not in possession of the modern way of expressing the powers of quantities. On the methods of facilitating such enormous computations, and on the details which still remained for the first calculators after they had applied all the analysis which they had, we have not here to speak; but we shall now show how the table may be formed by mere labour, and how the word logarithm arises.

Let us suppose that our system is to be such that, 0 being the logarithm of 1, a hundred thousand shall be the logarithm of 10. If the hundred thousandth root of 10 be extracted and called $1+t$, it would be found that 2 is very nearly the 30103rd power of $(1+t)$, that 3 is very nearly the 47712th power of $1+t$, and so on. If, then, beginning with 1, we increase it in the ratio of 1 to $1+t$, giving $1+t$; if we increase this in the ratio of 1 to $1+t$, giving $(1+t)^2$, and so on, it appears that we shall reach 2 (or very near to it, one way or other), when 30103 such ratios have been taken; or, if we pass from 1 to 10 by 100,000 steps, increasing each time in the same ratio, we shall come nearest to 2 in 30103 steps, which is therefore the number of times the increase is made in a certain ratio, or the number of the ratios, the *λογισμὸν ἀριθμὸς*, or the logarithm of 2.

In such a table it must of course follow that the logarithm of a product is exactly or very nearly the sum of the logarithms of the factors, since, for instance, 2 being $(1+t)^{30103}$ and 3 being $(1+t)^{47712}$ very nearly, 6 must be very nearly $(1+t)^{77815}$. Nor is this property altered if we divide or multiply all the logarithms by the same number. If, then, we divide every logarithm by 100000, the logarithm of 10 becomes 1, that of 2 becomes .30103, and that of 3 becomes .47712, as in the common tables.

It was evident from the first that the connection between a logarithm and its number must be of the following kind: when the logarithm increases in arithmetical progression, the number must increase in geometrical progression; so that, if a and $a+b$ be the logarithms of A and AB, then $a+2b$, $a+3b$, &c., must be the logarithms of AB^2 , AB^3 , &c. Several mathematicians had formed this conception; but the preliminary difficulty which stopped their progress was their being unable to present the series of natural numbers (or fractions of a high degree of nearness to them), in the shape of a geometrical progression. The great merit of Napier is threefold: first, he distinctly saw that all numbers, within any given limit, may be either terms, or as near as we please to terms, of a geometrical progression; secondly, he had the courage to undertake the enormous labour which was requisite for the purpose; thirdly, he made an anticipation of the differential calculus in developing the primary consequences of the definition.

It must be admitted that Briggs, by his construction of the decimal system, divides with Napier the merit of inventing logarithms, considered as an instrument of calculation. In the Napierian system the table must either be carried to an enormous length, or whole numbers only must have logarithms, and every logarithm of a fraction will require two entries of the table and a subtraction. But in Briggs' system, the logarithm of every decimal fraction can be found by one entry of the table, and one inspection of the fraction.

The peculiarity of this system (the base of which is 10) is as follows:—Every number or fraction is either a power of ten, positive or negative, or lies between two powers of ten. The powers of ten are ranged in the following table:—

10^{-4}	$10^0 = 1$	$10^1 = 10$
10^{-3}		$10^2 = 100$
10^{-2}		$10^3 = 1000$
10^{-1}		$10^4 = 10000$
		

From which the following rules may easily be obtained:—A number which has m figures before the decimal point lies between 10^{m-1} and 10^m , and its logarithm therefore lies between $m-1$ and m , or it is $m-1$ + a fraction less than unity. Also, if a fraction be less than unity, and if its first significant figure lie in the n th decimal place, this fraction lies between 10^{-n} and $10^{-(n-1)}$; so that its logarithm is $-n$ + a fraction less than unity. Now the convenience of Briggs' system lies in this, that the fraction less than unity, which is a part of every logarithm, does not depend on the position of the decimal point, but entirely upon the significant figures: the reason being, that an alteration of the position of the decimal point being a multiplication or division by some whole power of 10, alters the logarithm by the addition or subtraction of a whole number. This question is discussed in every treatise on the mode of using logarithms.

LOGIC. Logic, in the extensive signification of the term, offers Universal Criteria of Truth, the study of which affords a systematic discipline to the higher intellectual faculties. Logic and Mathematics are the two most ancient sciences and instruments of liberal culture. Under the various names, or in the various departments of Dialectic, Analytic, Organical or Instrumental Philosophy, the Method of Science, &c., the intellectual aspiration which produces logic, has, from Plato to Hegel, tended towards a practical SCIENCE OF SCIENCE, i.e., a science which should legislate for all the other sciences, providing reasoned methods of pure thought, and methods of applying thought to real existence. In the Dialectic of Plato we are raised above the details of the subordinate sciences, to the conception of science as an organic whole, and intellectual culture for its own sake. The mutual relations and the methods of the different parts of knowledge, with their respective offices in education, are contemplated; and the comprehensive doctrine thus suggested has, in its fragments, if not in its organic unity, maintained a central place in the liberal education of the world. Logicians, in the more strict conception of logic, are those who analyze science *as reasoned*, for the sake of speculative insight and pleasure, and for the practical direction of human understanding; as distinguished from metaphysicians, who, for similar ends, contemplate science *in its first principles*.

The materials for a Logical System were first reduced to comparative order by Aristotle, in the six treatises since collected under the name of the Organon. But the name logic is of later date than

Aristotle, and there is no definition of the contents of his *Organon* in his extant works. If we draw from the *Organon*, as we now have it, our conception of the nature of logic, we shall include in it a great deal that, according to one school of logicians, is foreign to

LOGIC is conversant about Syllogism, or reasoning expressed unelliptically. Accordingly, the *Organon* explains

1. The parts of a Syllogism.

2. The Syllogism itself.

One part of what is now included in logic, *i.e.*, the doctrine of proposition and syllogism, given in the book of *Enunciations* and in the *Prior Analytics*, has maintained to the present day the form it received from Aristotle. 'That logic' (*i.e.*, formal or syllogistic logic), says Kant, 'has proceeded in a sure course from the earliest times, is manifest from this, that since Aristotle it has not needed to retrace a step, unless in the way of clearing off useless subtleties, or developing with more precision what had been previously suggested—changes which belong rather to the scientific beauty than to the certainty of its doctrine. This much, however, is specially interesting in regard to logic, that since the time of Aristotle it has not been able to take a step in advance, and thus, to appearance, it has attained its perfect development.' Notwithstanding what Kant here says, it cannot be denied that the controversies which have been so frequent in regard to what the province of logic is, are due in a great measure to the example of Aristotle in his organical books. 'The book of *Categories*,' says Sir W. Hamilton, 'as containing an objective classification of real things, is metaphysical, not logical. The two books of *Posterior Analytics*, as solely conversant about demonstrative or necessary matter, transcend the limits of the formal science; and the same is true of the eight books of the *Topics*, as wholly occupied with probable matter, its accidents and applications. Even the two books of the *Prior Analytics*, in which the pure syllogism is considered, are swelled with extra logical discussions. . . . The same is true of the book on *Interpretation*; and matters are even worse with that on *Fallacies* (*Sophistic Elenchi*). If Aristotle, therefore, did more than any other philosopher for the progress of the science, he also did more than any other to overlay it with extraneous lumber, and to impede its development under a precise and elegant form.'

It is to be remembered that both Kant and Hamilton in these passages, mean by 'logic' exclusively what is now called Pure or Formal Logic. But the successive attempts to restrict the science to this narrow province have invariably produced dissatisfaction, and occasioned a reaction. A modified material or physical, as well as a pure or formal logic, is implied in the very conception of a science which has for its aim to provide universal and yet practical criteria of truth. Human science is

the science, while we shall exclude not a little that is essential to it, according to another. The following synopsis of the contents of the *Organon* exhibits its relation to Reasoning or Syllogism, that is, to truth or science regarded as reasoned:—

(a) With reference to Primary Notions, in the book of the *Categories*.

(b) With reference to Secondary Notions, in the book of *Enunciation* or Proposition.

(a) Generally, in the *Prior Analytics*.

(b) Specially, { Demonstrative Syllogism, in the *Posterior Analytics*.

{ Dialectical Syllogism, in the *Topics*.

{ Sophistical Syllogism, in the *Sophistic Elenchi*.

reasoned or generalized truth. It is knowledge of the many as one. It is knowledge by means of notions, concepts, or common terms. A science is a system of notions or concepts, in harmony with reality, relating to a special province of truth, and organized by means of reasonings. Now all science may be viewed in two aspects—a formal and a material—as formally true or as really true. The produce of our thoughts may be *formally perfect* without being *actually true*. Clearness, distinctness, precision, conclusiveness, consistency in the use of terms, and method, are some of the characteristics of *formal* truth; harmony between our clear, distinct, precise, conclusive, consistent, and methodical thoughts, and the actual order of external nature—between our concepts and the divine ideas expressed in the phenomena of the universe—constitute *material* truth.

Logicians, in their different schools, have attempted to analyze science, and to test truth in each of these aspects. Some have sought to determine both in one absolute science; others, by abstraction, to deal with the former with or without the latter, or with the latter with or without the former.

Logic, in different hands, has accordingly assumed different types. Two, broadly distinct, are apparent in its history. Of these the one is properly metaphysical or ontological; the other alone is properly logical.

When the two aspects of science—the abstract or formal, and the concrete or material—are merged in one, in obedience to the ontological aspiration after Absolute Science, indifferently called Logic or Metaphysics, we have systems of the first type, in which logic proper is merged in metaphysics or ontology. Of these the dialectic of Plato is one specimen, and the so-called logic of Hegel is another. These we relegate to metaphysics, to be criticized when it endeavours to determine the limits and essential nature of human science.

The 'logic' of Hegel is, in its conception, philosophy proper in its widest range. It is the professed science of that which in one aspect is Thought and in another Existence. Existence as objective, and existence as subjective, are its two momenta; and they are regarded as contained in consciousness in a unity, not abstract but concrete. The Hegelian logic is accordingly divided into the logic of Thought as *existence*, and of Thought as *such*—into objective and subjective logic. In this system the subjective logic,

which treats of Thought in notion, judgment, and reasoning or syllogism, is unfolded in intimate connection with the ontology, metaphysics, and cosmology—in a word, the absolute science—which are comprehended in Hegel's objective logic.

The logic of Hegel, like the dialectic of Plato, being relegated to Metaphysics or Ontology, we turn to those logical systems, less comprehensive in their aims, which seek to unfold and usefully apply the laws of reasoned thought as such; or to describe the conditions and rules to which reasoned thought should conform when it is engaged in the interpretation of nature—in short, the logic which provides for consistency in the use of words, and the logic which exhibits the nature and methods of inductive or experimental proof.

This formal and material logical system commences with Aristotle. It has assumed one or other of two phases, as the *formal* or the *material* truth and perfection of finite science has received the front place in its development. (In the *Organon* of Aristotle science is analyzed both formally and materially—as to its form, chiefly in the treatise on Enunciation and in the *Prior Analytics*; as to its matter, chiefly in the remaining treatises of the *Organon*.)

(I.) Does the logician attempt an analysis of the elements which constitute *formal* truth? In that case a system of Formal Logic is the result; and that system, developed in the Greek Analytic, has descended through the schools of the middle ages into modern philosophy, to be further purified and elaborated by Kant and Hamilton.

(II.) Is the material and especially the *physical* truth of science the ideal of the logician; and its rationale, with the methods of truly interpreting nature, the exclusive or principal object of his investigations? In that case logic becomes the theory and art of scientific induction, and Bacon, Locke, Bentham, Comte, and Mr. Mill appear among its chief names.

A complete system of logic, accordingly, comprehends both these, apparently conflicting, yet really harmonious parts—the formal, and the material or physical. It is the science of the laws of thought as such, and of the application of thought to nature in accordance with the principles of evidence.

Formal logic is a study of Notions, explicated and elaborated in judgments and reasonings; and, whether in the notional form, or as judgments and in reasonings, purified from their connection with things, and regarded exclusively as subject to necessary laws of thought. It is, in short, the science of thought or reasoning *as such*. Material or physical logic is a study of connected phenomena or Things, in the theory of their natural order, as invariably co-existing and successive, with the view to discover methods and rules for bringing our thoughts into harmony with that order. The former is the rationale of the conditions under which we *must* think when we think about anything; the latter consists of the methods, with their rationale, for extracting real or matter-of-fact science from the things about which we think. The logic of the one begins and ends with Necessary Truths; the interval between its primary axioms and its remote doctrinal conclusions being filled by a series of demonstrations conducted by aid of scientific symbols. The logic of the other is a

Code of Physical Discovery, which seeks for rules of observation and experiment that cannot be violated without an implied violation of our faith in the uniformity of nature; it begins and ends with what is contingent, as distinguished from what is formally necessary. The laws of non-contradiction, identity, and excluded middle are the regulating principles of the one; the mental tendency to trust in the constancy of natural order is the regulating principle of the other.

Pure or Formal Logic.—Coleridge speaks of his inability to conceive how any one can, by any spinning, make out more than ten or a dozen pages about syllogistic logic. Nevertheless, an elaborate science, with its axioms and postulates, was constructed by Aristotle, which, since the conception of the science was purified by Kant, has been renovated and extended by Hamilton. It now constitutes a beautifully developed framework, on which judgments and reasonings may be unfolded, and by which the consistency of our thoughts with one another may be tested.

Pure logic and pure geometry are both sciences of Quantity. They are both systems of demonstrations concerning the relation of whole and parts. But the 'wholes' or quantities of pure logic are different from those of pure geometry. Genera and species—in a word, notions or concepts—are the 'whole and parts' of logic; trinal extension constitutes mathematical quantity. All concepts or notions, whatever their special matter may be, are treated by the formal logician as *quantities*, which stand, in any and every science, in fixed quantitative relations to other concepts or notions.

The elementary doctrines of formal logic consist, accordingly, of an exposition of certain quantitative relations of Terms to one another, in Proposition and Syllogism, evolved by means of the axioms of Non-contradiction, Identity, and Excluded Middle, from the very nature of Concepts as such. The framework of this part of logic consists of *forms* for the reception and logical expression of concrete propositions, and *forms* for the reception and logical expression of concrete reasonings. Its problem is to find the various forms, into one or other of which all possible propositions and inferences may be analyzed. The purely scientific pages of a book of pure logic, even on a cursory glance, accordingly resemble the pages of a book in algebra. Symbols and symbolic notation take the place of common words and concrete examples. These symbols and formulas constitute the logical framework for the exposition and exposure of fallacies, and for testing the formal truth of valid reasonings. This, at least, is their practical function, and they imply a system of practical rules. Propositional and syllogistic forms compel us to complete, in the expression of our judgments and reasonings, what ordinary language elides; and in this view syllogism is valuable as an instrument which forces us to recognise fully the logical extent and relations of its dogmatically assumed, but often unproved and even indistinctly conceived premises. Syllogistic forms are practically interesting and available as the scientific apparatus for dragging into light specimens of verbal ambiguity, argumentative irrelevancy, and false assumption. Accordingly, formal logic may be described as a system of rules which afford a universal *formal* criterion of truth.

Recent scientific discussion and progress in this part of logic relates to the possible number and variety of the logical forms of assertion and ratiocination, and to the theory of their construction. Logic long satisfied itself with the four propositional forms signified by the letters A E I O. The various illative relations of these four forms produce the syllogistic forms prepared by the logician for the reception and expression of concrete reasonings, as our criteria for distinguishing valid inferences from invalid ones. Modern logicians have suggested more than one principle, by the application of which these old logical forms are modified and increased in number, thus professedly constituting a more philosophical or a more effective practical mechanism for the full logical exposure of our thoughts.

We may suppose an addition to the number of propositional and syllogistic forms to be made in two ways—by an express logical measurement or quantification of *both* the propositional terms—the 'predicate' as well as the 'subject,' instead of the subject only as in the Aristotelian Analytic; or by a more detailed (*e.g.*, an arithmetical or algebraical) measurement of the quantity of each term than the old logical signs of quantity ('all' and 'some') permit. The former of these two ways—the express and thoroughgoing quantification of the predicate—is the principle applied by Sir W. Hamilton for the expansion and simplification of the forms of logic; the latter is the logical novelty of Mr. De Morgan and other mathematical logicians. To discuss either principle in its theory, to exhibit its consequences in detail, and to announce and classify the formulas of which it is the parent, would be to write a treatise on Formal Logic. It is enough to say, that a re-organization of the whole scheme of logical forms is the necessary consequence of the application of either principle.

Take the former of these two principles—the express and thoroughgoing quantification of the predicate proposed by Sir W. Hamilton. Under this Hamiltonian analytic, as regards Propositions, subject and predicate become convertible; every proposition becomes an equation, and all conversion becomes simple: as regards Syllogisms, so called major and minor terms, major and minor premises, and the three figures are all made convertible into each other; Hypotheticals, alike in conjunctive and disjunctive reasonings, are shown to be merely complex varieties of the immediate inference of restriction or subalternation, and the syllogistic forms are professedly relieved of a load of exceptions, perversions, and rules. The differences of *quantity* and *quality* alone remain, and by these exclusively are terms, propositions, and syllogisms formally distinguished. Quantity and quality combined constitute the only real distinction of syllogistic Mood. Syllogistic figure vanishes, with its perplexing apparatus of special rules, and even the general rules of syllogism are reduced to a single compendious canon.

A classification of the principal varieties of Fallacy, or inconclusive reasoning, which syllogism, under either the old or the Hamiltonian analytic, is the test for detecting, along with an exposition of the nature and causes of Error, is an important part of logic, connecting the formal with the material or physical part of the system. The *scholastic* classification of

fallacies is grounded on Aristotle's *sophistical elenchi*; but the discussion of error and its causes by Bacon, Descartes, Malebranche, and Locke, has resolved this part of logic into an applied psychology of reasoning. The first book of the '*Novum Organum*' is a suggestive text in this transition part of the logical system.

That we think by means of *signs*—arbitrary and natural—is the one great occasion of fallacy and error. A classification of fallacies is a list of the principal species of invalid reasoning thus occasioned. And material logic, as a universal corrective of fallacies, seeks to provide against (1) the ambiguity of words, or artificial signs; and (2) the ambiguity of the phenomena of nature, or natural signs.

Material or Physical Logic.—We find ourselves in a department which touches upon what is more profound, although it is not so susceptible of exact demonstration, when we enter Material Logic—when we analyze Nature in its relations to thought, and with a view to determine the conditions of legitimate inductive generalization. We are contemplating the objective coherence of *natural* order, and the methods for unravelling its intricacies, instead of the subjective coherence of merely *notional* order, and the necessary forms for its consistent unelliptical expression. The *matter* of our reasonings, derived from experience, and not the *forms for their expression*, have here to be investigated. Nature, and our faith in its uniformity—the methods of research in what has been called inductive or imperfect reasoning, analogy, circumstantial evidence—in short, the methods of interpreting Testimony—whether the testimony of nature, or human and historical testimony—are among the problems proposed by modern science to physical logic, when it endeavours to find criteria of the actual truth of our premises concerning Nature or what is presentable in the senses, and not merely to test the conclusiveness or formal truth of the connection between assumed premises and alleged inferences from them.

This second part of logic is ostensibly a criterion of material or physical truth.

It professes to offer tests for distinguishing sufficiently proved inductive generalizations from mere analogies and hypotheses. It suggests criteria for determining the real truth of premises which depend upon observation and experiment. These are not fully *proved* unless ascertained by tests whose fallacy would imply a want of uniformity in the laws of nature. To reject a generalization attested by the criteria of material logic, is virtually to deny the constancy of natural order. The methods of inductive research, with their theory or rationale, constitute the essence of this part of the logical system, of which modern experimental science is the manifold illustration.

It may be added, that while inductive research, so far as it is merely observational and experimental, is not properly ratiocinative, the inferences we draw from our observations and experiments, including the rules or maxims according to which we draw them, may, as *reasonings*, be exhibited in syllogistic forms, and formally tested by syllogistic rules. Some logicians (as Hamilton) distinguish from one another the syllogistic forms of Induction and Deduction—the former being with them expressive of an ascent from particulars to the general, or from the less general to

the more general, of which the inductive conclusion is the *synthesis*; the latter, of a descent from the more general to the less general, or the particular, the deductive reasoning being virtually an *analysis*. But all reasoning implies reference to a reason, which in the case of 'inductive' reasonings—i.e., reasonings from an *imperfect* induction of instances, is the general rule believed to guarantee that the induction of instances, although 'imperfect,' is nevertheless sufficient. How man *becomes* capable of ratiocination, or endowed with the general truths required for eliciting scientific conclusions from the observations in which his experience commences, is the profound problem of the *origin* of knowledge or science, which logic refers to metaphysics. Do phenomena *blindly* generate his primary generalizations, or are these merely *elicited* on occasion of phenomenal signs being presented in sense?

On the whole, logic may be described as a system of *rules* which are a universal *formal* and *material* criterion of truth, and which are contemplated by the logician in their practical relation to the employment of thought, and also in their theoretical principles.

In its material or physical part logic merges in metaphysics; i.e., in the science of Being, or of Consciousness, or Science in its first principles. To metaphysics must be referred all the ultimate questions about the natural or sensible world in which we find ourselves, and to which our physical reasonings relate. This highest science, recognizing the apparent duality of our conscious existence, either tries with the Transcendentalist to resolve it into a unity that is above consciousness; or is content, with the Descendentalist, with a merely phenomenal universe of things, from which independent personality is excluded as an illusion; or occupies an intermediate position with the modest philosopher, who recognizes the finitude of our understanding, and, unable to solve the mystery of the existence revealed in the duality of consciousness, is ready to acknowledge its relativity, and to cultivate the faith in which it receives at least a practical solution.

Logic, formal and inductive, thus terminates face to face with a problem resembling that which engages the Hegelian logician throughout, and which the Hegelian professes to solve, while the metaphysic of faith confesses its ultimate insolubility by understanding. The phenomena and also the practical beliefs of which we are conscious—transient phenomena, and the 'testimonies' of our consciousness—are the watchword of this tentative metaphysics, in which we have the final outgoing of syllogistic and inductive logic. To ascertain by reflection the appearances really given in consciousness, and our genuine or defensible regulative beliefs concerning them, and to distinguish these last from the idols generated in individuals by accidental or unreasoned associations of their ideas, is the task to which it addresses itself, as it tries to recover the actual facts of our conscious life from the grasp of abstractions, to reconcile our conceptions of 'matter' and 'mind' with experience purified by analysis, and in so doing nourishes reverential feeling and religious faith in the contemplation of the ultimately unknowable by which we are encompassed on every side. This sort of study is the only possible 'science of Being,' as metaphysics was anciently defined; and

this metaphysical interpretation of Nature, as distinguished from practical methods of inductive-interpretation, is the exercise in which a logic of the formal and inductive criteria of truth properly culminates.

In the narrow compass of this article only a faint outline of the logical province, with its principal divisions and relations, has been attempted. The large recent development of logic, and the intellectual activity of which this is at once a cause and an effect, make it impossible, in a few sentences, to unfold scientific details, which are the reward only of the long-continued, patient, and systematic study through which this science awakens thought, and thus constitutes an invaluable and indeed indispensable organ in academical education.

LOGIER, JOHN BERNARD, author of the well-known Logierian system of musical instruments, and inventor of the key-bugle, was descended from a musical family, and born at Hesse-Cassel, in 1780. He received, at a very juvenile age, the first lessons on the piano-forte from his father, as well as a few rules on musical composition. His favourite instrument, however, was the flute; and in his tenth year he was able to play a double concerto in public. At the age of sixteen he was engaged as one of the band of the marquis of Abercorn's newly-raised regiment, in the north of Ireland. He now devoted himself to giving lessons in music; and it was about this period that the new system of facilitating the acquirement of musical knowledge presented itself to his mind. He first tried the experiment on his daughter, who laboured under an intractability of hand which appeared to defy all his efforts; and this led him to the invention of the chiroplast. In a few months his daughter was able to perform the duty of organist at Westport Church, in the county of Mayo, and afterwards to play a sonata in public. A patent for the chiroplast was obtained in 1814; and while in Dublin he delivered two courses of lectures on harmony, which excited the attention of the musical world. He then undertook to instruct a few young children, who had never learnt before, and three months afterwards he submitted them to a public examination. The result was, that several of the professors in Dublin immediately adopted Logier's system; and in the following year it found its way into England and Scotland. Professors from various parts came to Dublin to be initiated; and academies were soon established in Glasgow, Manchester, Chester, Preston, and other places. In 1816 Mr. Webbe, of London, paid Logier a visit; and was so satisfied with his system, that he soon introduced it into the metropolis, and his academy was resorted to by the first nobility. In 1821 M. Logier received a proposal from the king of Prussia to instruct twenty professors, through whom the system was to be taught and diffused through the Prussian dominions. He gladly accepted the invitation, and engaged to remain for three years, with a handsome house and academy, and a liberal remuneration.

From the year 1817 to 1827 the Logierian system flourished; and among other adherents was one no less distinguished than Kalkbrenner, who, with Mrs. Webbe, joined the inventor in establishing his London academy. He now enjoyed a long and prosperous career, dying in 1846, in his sixty-seventh year.

LOGOGRAM (Gr. *logos*, 'a word,' *gramma*, 'a letter'), a complicated form of the *anagram*, in which all the words that can possibly be formed out of a long word or sentence are extracted, and then singly changed into their synonyms, finally working the whole up into rhyme. The puzzle is to find out what the words are for which synonyms are used, and from them to ascertain the original word or sentence out of which they have all been extracted.

LOGOS, a Greek term meaning 'a word,' is used solely as a theological expression. It occurs repeatedly in the Chaldee Targums, where it commonly stands in the place of *Jehovah* in the Hebrew original. In the Apocrypha it is used to express the notion of an embodiment of divine wisdom. In the Platonic philosophy *logos* was the common term for 'plan of the cosmos,' or 'divine reason.' Later schools called *logos* a 'Hypostasis of Divinity,' a separate being, which, created out of the Creator, became the 'Son of the Creator.' In the New Testament this word is found only in the writings of John (Gospel, i.; 1st Epistle i. 1; Rev. xix. 13). These passages are generally ascribed to Christ; but the sense in which *logos* is to be taken, and the nature of the connection between this *logos* and the person of Christ are subjects of much dispute. The Trinitarian expositors assert that these passages can mean nothing else than that the *logos* is a distinct personal subsistence, which has existed from all eternity in a union of nature and of essence with God, which created the universe, and which was joined with a human nature to form the person of Christ. The Arian doctrine represents the *logos* as an emanation from the Deity, superior to all other created beings, and which supplied the place of a human soul in the person of Christ. Most Unitarian divines consider it to be used either for God himself, or as an abstract term for the wisdom and intelligence of God, which was fully imparted to Christ to fit him for his mission.

Those who attribute to the *logos* a personal existence give different reasons for the origin of the name. Some explain it to mean the *speaker* or *teacher*, by metonymy, as Christ is called by John the light, the way, the truth, and the life; others interpret it the *promised one*, and others consider that as speech is a *medium* of rational communication, so the name *logos* is given to the *mediator* between God and man, one who speaks to man in the name of God.

LOGRONO. [CASTILLA-LA-VIEJA.]

LOGWOOD, or **CAMPEACHY WOOD**, imported from the West Indies for the purposes of the dyer, is the wood of a low tree called *Hematoxylon Campechianum*. It belongs to the natural order *Leguminosæ*, and to the section *Cassieæ*. The wood is hard enough to take a fine polish, and is very durable. Its colouring matter, which is a blood-red, and becomes almost black after exposure, is dissolved both by water and alcohol, and it is principally derived from the presence of a peculiar body, to which Chevreul, who discovered it, gave the name of *hematin* or *hematoxylane*. Logwood is employed by the calico-printer to give a black or brown colour, the cloth being always first impregnated with alum mordant, and thus black is obtained. Iron mordant and logwood also yield a black, but it is not so good as with the alum mordant. Cloth with the alum mordant, dyed in a mixture of logwood and madder, has a fine

brown colour fixed upon it. Logwood is also used with other substances to produce various tints of violet, red, purple, and lilac. It is one of the ingredients in black ink, and also forms the basis of red ink when Brazil wood is not used. Of logwood the importation is larger than that of any other dye-wood used in Great Britain. The exact quantity received in 1864 was 41,625 tons, valued at 207,243*l*.

LOIR, River. [LOIR-ET-CHER.]

LOIR, NICHOLAS, was born at Paris in 1624. His father was an eminent jeweller, and he placed Nicholas with Sebastien Bourdon, and sent him afterwards, in 1647, to complete his studies in Rome. Here Loir studied chiefly the works of N. Poussin, and so carefully that in some instances it is said to be scarcely possible to distinguish his copies from the originals. He had great facility of execution, and excelled in various styles, as history, landscape, and architecture. In 1663 he was elected a member of the French Academy of Painting. He died at Paris, rector of the Academy, in 1679.

LOIR-ET-CHER, a department in France, formed chiefly out of the old province of Orléanais, is bounded N. by the department of Eure-et-Loir, E. by those of Loiret and Cher, S. by that of Indre, and W. by Indre-et-Loire and Sarthe. It extends from 47° 14' to 48° 7' N. lat., and from 0° 38' to 2° 14' E. long.: its length from N.W. to S.E. is 80 miles, the average width is about 38 miles. The area is 2452 square miles, and the population in 1861 was 269,029.

Surface and Rivers.—The surface presents numerous elevated and extensive plains, unbroken by any considerable hills and sloping gently to the south-west. The department is divided into two pretty equal parts by the Loire, along the banks of which run two chains of low hills, that have their slopes covered with vineyards and orchards. The district north of the Loire is drained by the *Loir*, which, rising in the south-west of Eure-et-Loir, flows south-east as far as Bonneval, and thence nearly south past Châteaudun to Vendôme, in this department. From Vendôme it runs nearly west, crossing the south of the department of Sarthe, and, reaching the boundary below La-Flèche, it enters the department of Maine-et-Loire, taking a south-western direction to its junction with the Sarthe on the left bank, nearly opposite the point where that river is joined by the Mayenne, about 5 miles north of Angers. The principal feeders of the Loir are the Ozane, the Yère, and the Braye on the right bank, and the Conie on the left. The whole length of the river is about 160 miles, 65 of which are navigable. The district south of the Loire is drained by the *CHER*, its feeder the Sauldre, and by the Beuvron and Cosson, which throw their waters into the Loire, near the village of Candé, below Blois. There are numerous ponds along the left bank of the Loire; and the south-east of the department, which is formed out of part of the old district of Sologne, now included in the arrondissement of Romorantin, presents a vast marshy plain. The department is crossed by the Orléans-Tours Railroad, which runs through Blois and along the right bank of the Loire; and by the Orléans-Vierzon line, which has 32 miles of its length in the south-east of this department.

Soil and Products.—The soil in the north-east, which includes a portion of the Beauce district, con-

sists of a dark rich loam ; in the south-east the arable lands are composed of strong clay and sand ; along the Cher the soil is calcareous. Agriculture is in rather a forward state ; large quantities of bread-stuffs are raised, much more than supplies the home consumption. Of wine, the annual produce is about 13,000,000 gallons, a large portion of which is distilled into brandy. The department yields, besides excellent fruits and vegetables, beet-root, hemp, &c. The Sologne sheep are extolled for the fineness of their wool ; but the horses of that district, though hardy, are small and ill-formed. Black cattle are of inferior breed. The arrondissement of Vendôme is famous for its breed of draught horses. The rivers and ponds abound in fish ; the Sologne marshes and ponds supply also a considerable quantity of good leeches. The department contains a good deal of natural and artificial grass-land ; and in the arrondissement of Romorantin there are large pine woods. The climate is in general mild and healthy, except in the marshy district of Sologne.

Iron mines are worked ; alabaster, building stone, and gun-flints are quarried ; marl and potter's clay are found.

The manufactures consist of coarse woollens, blankets, swanskin, cotton cloth, hosiery, leather gloves, beet-root sugar, woollen yarn, leather, glass, and earthenware.

Divisions and Chief Towns.—The area of the department is 1,569,000 acres, and is divided into three arrondissements, which, with their subdivisions and populations, are as follows :—

Arronds.	Cantons.	Communes.	Pop.in1861.
Blois, . . .	10	139	137,699
Romorantin, . .	6	49	51,957
Vendôme, . .	8	110	79,373
Total, . . .	24	298	269,029

Of the arrondissement of Blois, and of the whole department, the capital is BLOIS. *Mer*, N.E. of Blois, on the right bank of the Loire, has 4776 inhabitants, who manufacture leather, and trade in wine, brandy, and vinegar. Close to *Mer* is *Menars*, where there is a very fine château, now belonging to Prince de Chimay, who has established a college in it. *Montrichard*, formerly an important fortress, defended by a strong castle, now in ruins, is situated on a hill on the right bank of the Cher, 18 miles S. from Blois, and has 2807 inhabitants. The ancient walls of the town, which are pierced by four gates and flanked with towers, are still in a good state of preservation. Near *St.-Aignan*, a small town on the left bank of the Cher, with 3600 inhabitants, are the great gun-flint quarries from which the French armies were supplied.

In the arrondissement of Romorantin, the chief town, *Romorantin*, stands at the junction of the Morantin with the Saultre, 24 miles S.E. from Blois, and has tribunals of first instance and of commerce, a college, and 7642 inhabitants. The town, formerly ill built, has been considerably improved of late years, the streets having been widened and laid out more regularly, houses erected in a modern style, and the roadways well paved. It has important manufac-

tures of cloth and woollen stuffs, several spinning factories, tanyards, and parchment mills. *Selles-sur-Cher*, situated in a fertile country, 10 miles S.W. from Romorantin, on the Cher, which is here spanned by a fine bridge, has 4672 inhabitants, who manufacture cloth, and trade in corn, wine, &c. At one end of the town stands a fine château, erected by Philippe de Bethune, the brother of Sully.

In the arrondissement of Vendôme, the chief town, *Vendôme*, prettily situated on the slope of a vine-clad hill, above the Loir, which here divides into two branches, stands 19 miles N.W. from Blois, and has a tribunal of first instance, a college, and 9356 inhabitants, who manufacture woollen stuffs, gloves, cotton yarn, calico, leather, and paper. The town is well built. On the height above it are the ruins of the old castle of the dukes of Vendôme, from which there is a fine view of the scenery of the Loir. Among the more remarkable structures are the church of La-Sainte-Trinité, the Benedictine monastery, now used as a barrack; the desecrated church of St.-Martin, now converted into a corn market; the college buildings, and the theatre. *Mondoubleau*, a small place of 1621 inhabitants, is prettily situated on a hill above the Graisse, a small feeder of the Braye, 15 miles N.W. from Vendôme. A fine old castle, with walls, towers, and ditches still nearly entire, stands above the town, and formed one of the chain of fortresses that defended the frontier of the old province of Maine. *Montoir*, a pretty town on the right bank of the Loir, and at the foot of a hill crowned by the château of St. Outille, has 3099 inhabitants, who manufacture linen, woollen hosiery, and leather. The church of St.-Gilles, the interior of which is richly ornamented with frescoes, and the handsome square in the centre of the town, are the most remarkable objects. *Savigny*, near the left bank of the Braye, in the north-west of the department, has a population of 2966.

The department forms the see of the bishop of Blois, is included in the jurisdiction of the Cour Impériale of Orleans, and University Academy of Paris, and belongs to the eighteenth Military Division, of which Tours is head-quarters. It has two representatives in the Chamber of Deputies. (*Dictionnaire de la France; Annuaire pour l'An 1866.*)

LOIRE (the *Liger* or *Ligeris* of the Romans), a river in France, the basin of which is bounded E. by the Cévennes ; N. by the mountains of Morvan, the heights of Beauce, and the Menez mountains ; and S. and S.W. by the Margeride mountains, and the volcanic group of Auvergne, with its ramifications westwards to the Atlantic. The limits thus described include a fourth part of France. The greatest length of the basin from N.W. to S.E. is 370 miles ; its greatest breadth, 224 miles. Its area is estimated at 50,783 square miles.

The Loire rises in Mont Gerbier-des-Jones, one of the Cévennes, in the neighbourhood of Mont Mézin, in the department of Ardèche. The general direction of its course is at first north, then north-west to Orléans, where it turns westward, and continues in this direction to its entrance into the Atlantic, 36 miles below Nantes. The number of streams received by the Loire is very great ; its navigable feeders from the right bank are the Arroux, the Maine (formed by the junction of the Mayenne and the Sarthe ; from

the left—the Allier, the Loiret, the Cher, the Indre, the Vienne, the Thouët, the Sèvre Nantaise, and the Achenau, all of which, with their feeders, give a total amount of internal navigation of about 1300 miles. In the upper part of its course, above the junction of the Allier, the valley of the Loire is narrow. At its source the Loire is about 4600 feet above the sea-level; below Nevers, at its junction with the Allier, 550 feet; at Orléans, 294 feet; a little below Tours, 160 feet; at the junction of the Mayenne, 115 feet; and at Nantes, 83 feet above the sea-level.

The whole course of the Loire is about 600 miles, of which 505 are navigable; but of these, 44 miles, from La-Noirie to Roanne, are navigable down the stream only. For two-thirds of the distance above Roanne, the Loire is available for floating timber.

This river, with its larger affluents, constitutes the great outlet for the produce of central and western France. The banks are celebrated for their beauty, particularly in the neighbourhood of Tours. From the melting of the snows in the Cévennes, in which it has its source, the Loire is subject to great inundations, to prevent which it has been embanked in the level tracts below Orléans. [INDRE-ET-LOIRE.] The sand and soil which its waters bring down form islands or shifting banks in its course, which materially impede the navigation, especially above Orléans: to avoid this inconvenience, a canal has been formed along the left bank of the river, from the Canal du Centre, at the junction of the Arroux, to the Canal de Briare, at Briare near Gien. The tide flows about 40 miles up the river, to a short distance above Nantes. [LOIRE INFÉRIEURE; NANTES.] The Loire is connected with the Saône by the Canal du Centre, with the Seine by the Canals de Briare, d'Orléans, and du Loing, and with Brest harbour by the canal from Nantes to Brest.

LOIRE, a department in France, comprising the greater part of the district of Forez, is bounded N. by the department of Saône-et-Loire, E. by those of Rhone and Isère, S. by those of Ardèche and Haute Loire, and W. by those of Puy-de-Dôme and Allier. It extends from 45° 13' to 46° 17' N. lat., and from 3° 41' to 4° 45' E. long.; its greatest length is 77 miles, its average width is about 29 miles. The area is 1838 square miles, and the population in 1861 was 517,603.

Surface.—The department belongs almost entirely to the basin of the Loire, which is separated from that of the Rhône by the Cévennes mountains on the east, and from that of the Allier by a secondary chain of the Cévennes mountains on the west. The interior may be described as two large inclined planes descending from these two mountain ranges, and intersecting in the water-line of the Loire; but as the mountains, in their course northwards, trend off respectively in directions nearly N.N.E. and N.N.W., the northern portion of the department has more the appearance of a single wide plain, which includes part of the former provinces of Beaujolais and Bourbonnais, and is called the plain of Roanne. The rest of the department is called the plain of Forez; and between it and the plain of Roanne the division is marked by a chain of hills running E. and W., and uniting the two mountain ranges before named, except at the point where it is broken through by the Loire. A small portion of the south-east of

the department extends eastwards of the Cévennes into the basin of the Rhône, which river runs along the boundary for about 6 miles. In the western part of the plain of Forez several isolated volcanic swells, consisting of black basalt, lie in a general direction of N. and S., and have their summits crowned with the ruins of ancient castles or monasteries.

Rivers.—The principal rivers are the LOIRE and the RHÔNE, by means of which the various industrial products of the department are conveyed to the Atlantic or to the Mediterranean. The Loire is navigable, in its whole length, in this department to which it gives name; but owing to the rapidity of the current, it is only the down navigation that is available as far as Roanne, where the general navigation of the river commences. Its principal feeders are the Ondène, the Furens, the Coise, the Lignon, and the Sornin. The Gier is the only feeder the Rhône receives in this part of its course. The lateral canal of the Loire from Roanne to Digoin runs through the north of the department; another canal runs from Rivede-Gier to the Rhône. A railroad runs along the right bank of the Loire, from Roanne to St.-Étienne, near which it crosses the Cévennes, and continues up the valley of the Rhône to Lyons; its length is 79 miles.

Products and Manufactures.—The mountains of the Loire abound with excellent pasture and medicinal plants; their lower slopes are cultivated or covered with vineyards and chestnut woods. In the plains the common bread-stuffs are grown, but in quantity insufficient for the consumption; hemp, excellent fruits, oleaginous seeds, and dyestuffs are also raised. About 6,000,000 gallons of good red and white wines are produced annually. Horses and black cattle are small; the sheep are noted for their sweet flesh; poultry and game are abundant. In the valley of the Rhône, mulberry trees are extensively grown for the production of silk. There are also extensive forests of pine, fir, beech, and oak; on Mont Pilat, near St.-Étienne, an immense number of deals are made, saw-mills being established on every available stream of water. But much of the finest pine timber is made into charcoal, in consequence of the great difficulty of transport from the mountain-heights on which it grows; the finest trees vary from 98 to 115 feet in height. Great quantities of chestnuts are grown; these enter largely into the food of the people; the finest are sent to Paris, where they are sold (like those of Ardèche) under the name of *marrons de Lyon*.

The department contains one of the richest coal-beds in France, which besides feeding the numerous factories and furnaces of St.-Étienne, and other places in the department, furnishes large portions for exportation to Lyons and the towns on the Rhône. The quantity of coal annually furnished by the mines of Loire amount to one-third of all the coal raised in France. Lead and iron mines are also worked; building stone, granite, potter's clay, &c., are found; mineral springs are numerous.

The manufactures are of the greatest variety and importance, and give rise to a very extensive commerce. The chief products are fire-arms, iron-mongery, and machinery of all kinds, silks, ribands, crape, velvet, plush, laces, linen, cotton, glass, bricks, steel, iron, scythes, hardware, canvas, mill-castings, files and tools of all descriptions, cotton and linen

yarn, lace, cutlery, earthenware, tiles, lime, &c., &c. Great numbers of coal barges and canal boats are built at Roanne and St.-Rambert. The great centre of manufacturing industry is St.-Étienne.

Divisions, Chief Towns, &c.—The department contains 1,176,000 acres, and is divided into three arrondissements, which, with their subdivisions and population, are as follows:—

Arronds.	Cantons.	Communes.	Pop. in 1861.
Montbrison,	9	138	132,042
Roanne, . .	10	110	146,495
St.-Étienne,	11	72	239,066
Total, .	30	320	517,603

Of the arrondissement of Montbrison, the chief town, *Montbrison*, stands on the Vizézy, a small feeder of the Loire, in 45° 36' N. lat., 4° 3' 45" E. long., at a distance of 45 miles W. from Lyons, and has 7201 inhabitants. It is built round a basaltic hill (from the summit of which there is a fine view over the plain of Forez), and at the extremity of a branch railroad that joins the St.-Étienne-Roanne line at Montrond. The town, which is ill built, with narrow winding streets and low houses, has a tribunal of first instance, communal and ecclesiastical colleges, a primary normal school, and a public library of 15,000 volumes. The principal building is the cathedral of Notre-Dame. The old ramparts and ditches are now replaced by handsome promenades. Montbrison is the capital of the department of Loire, which distinction it owes solely to its central situation; for with respect to population, or commercial and industrial activity, it is greatly surpassed by St.-Étienne and Roanne. *St.-Bonnet-le-Château*, on a high hill in the south of the department, and on the Roman road made here by Agrippa, has 2230 inhabitants. *Chazelles-sur-Lyon*, a small but well-built walled town east of Montbrison, has a population of 5332. *Feurs*, the ancient *Segusianorum*, and the midway station on the railroad from St.-Étienne to Roanne, from each of which towns it is 25 miles distant, stands in a fertile, well-watered plain near the right bank of the Loire, and has 2823 inhabitants. The Roman antiquities found in the town are numerous; the high stone dykes which confine the Loire in the neighbourhood are said to be of Roman construction. *St.-Galmier*, 12 miles E. of Montbrison, on the St.-Étienne-Roanne Railroad, stands on a high hill near the right bank of the Coise, and has a population of 2954. It is said to occupy the site of the ancient *Aquæ-Segeste*, and is still famous for its cold mineral spring. *St.-Rambert*, 11 miles S.E. from Montbrison, is prettily situated on the left bank of the Loire, and has 2545 inhabitants. The church of St.-Rambert is remarkable for its great antiquity. Nearly 3000 barges are built here annually, and sent down the Loire laden with coal to Roanne. In the neighbourhood are several iron forges and smelting furnaces. *Surv-le-Comtal*, 7 miles S. from St.-Rambert, for a long time the residence of the counts of Forez, whose castle is still in good preservation, has 2770 inhabitants.

In the arrondissement of Roanne, the chief town, *Roanne*, is situated on the left bank of the Loire,

which is here navigable, at a distance of 50 miles by railroad from St.-Étienne, and has a tribunal of first instance, a consultative chamber of manufactures, a college, and 17,398 inhabitants. The town is well built, with straight wide streets, formed by handsome houses; the new bridge over the Loire, the public library, and the college buildings are the most remarkable structures. The manufactures, which are important, consist of muslin, calico, broad-cloth, handkerchiefs, glue, oil, porcelain, linen thread, cotton yarn, and leather; there are several dye-houses, and numerous boat-building yards. By means of the lateral canal of the Loire, which enters that river at Digoin, and by the numerous canals and rivers that join the Loire, Roanne has water communication with all the principal towns in France. The trade in corn, wine, flour, spun cotton, calico, planks, charcoal, the manufactures of Lyons, and of the southern and eastern departments of France, is very considerable. *Belmont*, 3 miles N.E. from Roanne, has 3592 inhabitants. *Charlieu*, 12 miles N. by E. of Roanne, on the Sorin, a feeder of the Loire, is famous for the remains of a Benedictine abbey, and has 3936 inhabitants, who manufacture linen, cotton, silk and cotton yarn, and shoe and glove leather. The hospital of Charlieu, one of the oldest in France, was founded by St. Louis. *Perreux*, on the Rodon, 4 miles from Roanne, has 2552 inhabitants. *St.-Symphorien-de-Lay*, 10 miles S.E. from Roanne, has cotton factories, coal mines, and 4652 inhabitants.

Of the arrondissement of St.-Étienne, the chief town is *St.-Étienne*. [*ÉTIENNE, St.*] *Bourg-Argental*, on the Déôme, in a fertile valley abounding with mulberry plantations, from which silk of the best quality is produced, stands 18 miles S. from St.-Étienne, and has 3535 inhabitants. *Le Chambon*, 3 miles from St.-Étienne, is situated on the Dondaine-Vachery, and has 5514 inhabitants, who manufacture ribands, iron and steel ware, table cutlery, pocket-knives, &c. *St.-Chamond*, beautifully situated at the confluence of the Gier and the Janon, 7½ miles N.E. from St.-Étienne, and near the Lyons-St.-Étienne Railway, is a busy manufacturing town, containing a consultative chamber of manufactures, a conseil des prud'hommes, and 11,626 inhabitants. The town is well built, and presents a great number of elegant houses inclosed in gardens. The church of St.-Chamond, the public baths, and promenades, are among the most remarkable objects. There are extensive coal mines, iron forges, and smelting furnaces in the environs. The town contains a great number of silk mills, and has important manufactures of ribands, stay-laces, nails for the navy, hardware, &c. *St.-Genest-Malifaux*, 9 miles S. from St.-Étienne, near the right bank of the Semène, has a population of 3517. *St.-Héand*, 6 miles N. from St.-Étienne, contains silk mills, and 3612 inhabitants. *Pélussin*, situated at the foot of Mont Pilat, at a short distance from the Rhône, and in a fertile vine district, has 4039 inhabitants. The preparation of raw silk for manufactures, and the working of the porphyry quarries of the neighbourhood, afford employment to a considerable part of the population. *Rive-de-Gier*, 13 miles N.E. from St.-Étienne, on the Lyons-St.-Étienne Railroad, previous to 1815 had under 4000 inhabitants; it now has a population of 14,202. It is built on the Gier, here crossed by

several bridges, and rendered navigable by the Canal-de-Givors, which runs from this town to Givors on the Rhône. The town owes its prosperity to the coal mines, exceeding forty in number, which are worked in the neighbourhood. The basin of the canal is lined with quays, backed by vast coal stores. The reservoir of the Canal-de-Givors, a little S. of the town, is formed by massive mason-work, and is a fine work of its kind. Besides its great trade in coal, with which Lyons and several other places are supplied, Rive-de-Gier has above forty glass works, steam engine factories, iron foundries and forges, steel works, silk mills, riband factories, &c.

The department is in the see of the archbishop of Lyons; it is comprised in the jurisdiction of the Cour Impériale and Academy of Lyons, and is included in the eighth Military Division, of which Lyons is head-quarters. It has four representatives in the Chamber of Deputies.

(*Dictionnaire de la France; Annuaire pour l'An 1866; Statistique de la France.*)

LOIRE, HAUTE, a department in France, comprising the district of Vélay and parts of Gévaudan, Forez, and Auvergne, takes its name from its situation in the upper part of the basin of the Loire, and is bounded N. by the departments of Puy-de-Dôme and Loire, E. by Ardèche, S. by Lozère, and W. by Cantal. Its greatest length from E. to W. is 69 miles, from N. to S. 46 miles; it extends from 44° 44' to 45° 25' N. lat., and from 3° 4' to 4° 26' E. long. The area is 1925 square miles, and the population in 1861 was 305,521.

Surface and Hydrography.—The department is mountainous. The Cantal mountains, and the Margeride chain, which unites them to the Cévennes, cover with their off-shoots so much of the south-west and south of the department as lies on the left bank of the Allier: the south-eastern and eastern districts are occupied with the mass of the Cévennes, from which a secondary chain, running through the interior nearly N. and S., forms the watershed between the Allier and the Loire, and is joined, near Chaise-Dieu, by another range that runs N.W. from Mont Mezenc, the culminating point of the Cévennes [CÉVENNES; ARDÈCHE]. The country, thus surrounded and traversed by mountains, is furrowed by numerous rivers, brooks, and torrents, which flow, with rapid descent, either between steep banks that expose to view the volcanic formation of the rocks, or through picturesque and fertile valleys whereof the soil consists of decomposed lava and other volcanic deposits. On the mountains, which present numerous conical peaks and craters, and have their summits covered with snow during five or six months in the year, there are large forests and extensive pastures, where great numbers of cattle and mules, the chief wealth of the country, are reared. The lower slopes are covered with chestnut woods and vineyards. In the north-west and north-east of the department there are some extensive plains of considerable fertility, all covered with a soil of decomposed volcanic matter.

The principal rivers are the ALLIER, which drains the west of the department; and the LOIRE, which, swelled by the Gazeille, the Lignon, and the Somme, from the right bank, and by the Borne, the Arzon, and the Ancy, from the left, drains the central and eastern districts.

Products and Manufactures.—The agricultural produce of the department suffices the consumption. The usual crops are wheat, rye, barley, oats, meslin, beans, &c.; fruits are abundant. Of wine only 1,264,000 gallons are produced, and this is of inferior quality. Mules are reared and horned cattle and pigs are fatted in great numbers. Among the wild animals are boars, wolves, foxes, wild cats, badgers, &c.

The geological structure and mineral wealth of the department are of great variety, though the latter is not turned to much advantage. The mountain-range which runs north-west from Mont Mezenc consists of trachytic rocks, and is reckoned among the most ancient of the volcanic structures of central France. The district of Vélay, which lies S. and S.W. of this range, and comprises nearly all the south of the department, is occupied with basaltic rocks and lava beds, the great antiquity of which is proved by their being covered with a soil formed by the decomposition of their surface. Along the banks of the rivers in this district the basaltic columns laid bare to view assume a variety of beautiful forms; and the charred fragments of ancient eruptions, which were long subsequently rolled and worn in watercourses that have disappeared for ever, are seen in many places deposited in beds of clay and marl, piled up alternately one upon the other. Among the primitive rocks are found granite, gneiss, quartz, mica schist, &c. Coal, lead, and antimony mines are worked; iron and copper ores are found at various points. Chalcedony, diamond-spar, sapphires, amethysts, tourmalines, &c., are found, and also marble, millstone grit, plaster of Paris, &c., &c. Mineral springs are numerous; they are all saline or acidulous.

The manufactures consist of common articles of necessity and use, and are unimportant, with the exception of silk and thread lace and ribands. The people are in general poor, and many of them emigrate during the winter months as sawyers, hawkers, porters, sweeps, &c.

In a country the highest point of which, Mont Mezenc, is 5820 feet above the sea-level, whilst its lowest point, namely, where the Allier crosses the northern border, is only 1279 feet above the same level, there is room for very great variety of climate and season. Seed-time and harvest differ in different cantons according to the elevation, the maximum variation amounting to as much as two months; and such is the difference of climate, that while in some districts the vine flourishes, in others rye will hardly ripen. The south-west wind blows at times for weeks continually, and with great violence; the west and north-west winds bring rain.

Divisions and Chief Towns.—The department contains 1,232,000 acres, and is divided into three arrondissements, which with their subdivisions and population are as follows:—

Arronds.	Cantons.	Communes.	Pop. in 1861.
Le-Puy, . .	14	114	136,563
Yssengeaux, .	6	40	87,741
Brioude, . .	8	106	81,217
Total, . .	28	260	305,521

In the arrondissement of Le-Puy, the chief town, *Le-Puy*, which is now the capital of the whole department, as it formerly was of the district of Velay, is situated at the foot and around the southern slope of a steep hill, at the junction of three pretty valleys, watered respectively by the Loire, the Borne, and the Dolaison, in $45^{\circ} 2' 46''$ N. lat., and $3^{\circ} 52' 55''$ E. long., 66 miles S.W. from Lyons, and has 17,045 inhabitants. Except the broad street at the foot of the hill, through which the roads from Clermont and Lyons run, the rest of the town is built in the form of an amphitheatre round the steep sides of Mont Anis, which is surmounted by a lofty basaltic rock called Cornielle. From a distance Le-Puy presents a most picturesque appearance; but the interior view disappoints the expectations thus raised. The streets are irregular, narrow, and in the upper part of the town inaccessible to carriages; they are paved with volcanic breccia, which in all weathers is slippery and dangerous to walk upon. The most important structures are—the cathedral, situated in the highest part of the town; the church of St.-Laurent, situated at the foot of the hill, and containing the monument and part of the remains of Du Guesclin; the prefect's residence in the spacious square of Du-Breuil; the college church; the museum, near the cathedral, in which are numerous paintings, Roman antiquities, and one of the best collections of geological and mineralogical specimens in France; the theatre, an ancient structure, supposed to have been a heathen temple; the ecclesiastical college; and the Parnassac gate, a fine specimen of military architecture over one of the promenades of the town. Le-Puy is the seat of a bishop, and contains tribunals of first instance and of commerce, a consultative chamber of manufactures, a college, a public library, and various literary and scientific societies. In the suburb de l'Aiguille is an isolated basaltic rock of pyramidal form, and 285 feet high, which is ascended by a staircase of 218 steps cut in the rock, and is surmounted by the highly-ornamented chapel of St.-Michel, erected in the tenth century. Between this rock and that of Cornielle stands a heptagonal building, said to have been a chapel dedicated to St. Clair, and now used as a corn-store. The chief industrial products of Le-Puy are lace, coarse woollens, vine-skins, nails, and leather; the commerce is in these articles, and in corn, iron, pottery, cattle, &c. *Craponne*, 17 miles N. from Le-Puy, has a population of 2630. *Le-Monastier*, 11 miles S.E. from Le-Puy, has a population of 3589. *St.-Paulien*, built on the ruins of an ancient city, said to be Ruessium or Revesia Vellavorum, has a population of 2932; several Roman coins, vases, monuments with inscriptions, have been found, and are preserved here. *Saugues*, a town of 3839 inhabitants, stands in a rich corn and pasture country, 16 miles W.S.W. from Le-Puy, and has some woollen manufactures. Just outside the walls is a monument of rudely-cut stone without inscription, which is traditionally called the Tomb of the English General.

In the arrondissement of Yssengeaux, the chief town, *Yssengeaux* or *Issengeaux*, an ill-built gloomy place, is situated on a high hill 14 miles N.E. of Le-Puy, and has a tribunal of first instance, a college, and 7971 inhabitants, who manufacture silk, lace, and ribands, and trade in timber, cattle, sheep, &c.

Bas-en-Basset, on the left bank of the Loire, 12 miles from Yssengeaux, has 3189 inhabitants, who manufacture lace and pottery. The town, which is commanded by the old castle of Rochebaron, has a mineral spring. *St.-Didier*, 14 miles N.E. from Yssengeaux, has silk factories and 5220 inhabitants, who manufacture ribands and articles in papier-maché. *Monistrol*, 12 miles N.E. from Yssengeaux, near the right bank of the Loire, is an ugly ill-built town, with an important corn-market, and 4473 inhabitants, who manufacture lace, ribands, hardware, satin, silk handkerchiefs, leather, and papier-maché articles. *Tence*, a manufacturing town of 5537 inhabitants, is prettily situated on the right bank of the Lignon, 9 miles E. by S. from Yssengeaux.

In the arrondissement of Brioude, the chief town, *Brioude*, is situated 29 miles N.W. from Le-Puy, near the left bank of the Allier, and has tribunals of first instance and of commerce, a college, and 4950 inhabitants. It is an ill-built town. The most remarkable structures are the church of St.-Julien and the college buildings. *La-Chaise-Dieu*, 15 miles E. from Brioude, a town of 1722 inhabitants, takes its name from the famous monastery of Chaise-Dieu (Casa Dei), which, with the exception of the church, was destroyed during the revolution of 1793. The abbey church, erected about the middle of the fourteenth century, at the expense of Pope Clement VI., a native of Chaise-Dieu, is considered one of the finest abbey churches remaining in France; it contains tombs of Clement VI. and Gregory XI., some very ancient tapestries, and is greatly admired for the carved woodwork of the 156 stalls in the choir. The walls of the choir are ornamented with ancient paintings in fresco, representing the allegory of the Dance of Death. *Langeac*, built in a pretty situation, on the left bank of the Allier, has 3491 inhabitants. There are coal mines and stone quarries near this town.

The department forms the see of the bishop of Le-Puy, is included in the jurisdiction of the Cour Impériale of Riom, and of the Academy of Clermont, and belongs to the twentieth Military Division, of which Clermont is head-quarters. It has two representatives in the Chamber of Deputies.

(*Dictionnaire de la France*; Malte Brun, *Géographie Universelle*; *Annuaire pour l'An 1866*.)

LOIRE INFÉRIEURE, a department in France formed out of a part of Bretagne, and lying along the lower course and the mouth of the Loire, is bounded N. by the departments of Morbihan and Ile-et-Vilaine, E. by those of Mayenne and Maine-et-Loire, S. by that of Vendée, and W. by the Bay of Biscay. It extends from $46^{\circ} 52'$ to $47^{\circ} 52'$ N. lat., and from $0^{\circ} 55'$ to $2^{\circ} 32'$ W. long.; its greatest length from E. to W. is 74 miles, from N. to S. 69 miles. The area is 2632 square miles, and the population in 1861 was 580,207.

Surface and Hydrography.—The coast line is about 55 miles in length. It presents an irregular outline, broken in the north by the bays of Pennebe and Pembron, which are separated by the promontory of Piriac; in the centre by the embouchure of the Loire, to the north of which are some small islets; and in the south by the large Bay of Bourgneuf. Considerable salt marshes lie along this coast. The surface of the department is level, with the exception of a line of

low hills, which crosses it in the north, forming the watershed between the Loire and the Vilaine. The principal river is the Loire, which enters the department below Ingrande in Maine-et-Loire, and divides it into two unequal parts. It is 5 miles wide at its mouth, and is navigable for large vessels up to Nantes, to a few miles above which the tide ascends. The principal feeders of the Loire in this department are, from the left, the Sèvre-Nantaise and the Achenau, which last is the outlet of the lake of Grand-Lieu; from the right, the Erdre, which enters the Loire at Nantes. The Vilaine touches the department on the north-west, receiving the Don and the Isac. The other most considerable rivers are the Maine and the Moine, feeders of the Sèvre-Nantaise; the Ognon and Boulogne, which flow from Vendée into the Lake of Grand-Lieu; the Brivé, which enters the Loire above St.-Nazaire; and the Tenu, a feeder of the Achenau. The department is crossed by the canal from Nantes to Brest. The climate is healthy, although somewhat damp; the heat in summer is often very great.

Grand-Lieu, the largest lake in France, and the reservoir for the waters of the Boulogne, the Ognon, and some smaller streams, is situated near the left bank of the Loire, with which it has communication by its navigable outlet the Achenau. It has an area of 29 square miles, and abounds in fish; its shores are marshy. North of the Loire there lie many small lakes, and extensive marshes and bogs.

Products.—The quantity of cereal grain produced suffices the consumption. The chief crops of this kind are wheat, rye, buckwheat, and meslin. Barley is grown in small quantity. The meadows and pastures along the Loire, in the islands formed by the deposits of the river, and in the neighbourhood of the marshes, are excellent. Cattle of good breed are very numerous; horses, of which also great numbers are reared, are small. The apple tree is extensively cultivated north of the Loire for making cider; and in the same district there are forests of vast extent. The *Bocage* district, which stretches south-east of the Lac du Grand-Lieu, is well wooded, as the name implies, every field being inclosed with hedgerows and lines of timber trees. The vineyards of the department yield 32,200,000 gallons of wine annually, rather less than a third of which is used for the home consumption; of the surplus, part goes to the supply of Paris, some is distilled into brandy, and the rest is sent to Orléans to be converted into vinegar. The wines are considered of middling quality; the sweet wines are prized for their agreeable flavour, and for their keeping qualities. Fishing affords occupation to a great number of the inhabitants.

Granite, quartz, mica, kaolin, and feldspar are found in the arrondissement of Nantes; in that of Châteaubriant extensive slate quarries are worked, and iron ore is abundant, supplying many forges, blast-furnaces, and foundries. In the arrondissements of Châteaubriant and Ancenis there are important mines of coal of excellent quality; magnetic iron is found in isolated particles on the surface of the ground on the right shore of the embouchure of the Loire. There are mineral springs and sea-bathing establishments at Plaine and Pornic.

Manufactures and Commerce.—The principal

manufactures are linen, calico, printed cotton, serge, and coarse woollen stuffs; shipbuilding is carried on at Nantes, Paimbœuf, and Pellerin; and at Indret, one of the small islands in the Loire, there are establishments for the manufacture of steam-machinery, and also slips for building steam-frigates. Other articles of industrial produce are paper, leather, porcelain, glass, ship cordage, chain cables, cotton yarn, refined sugar, &c. [NANTES.]

The department has an important commerce with foreign countries, coastwise, and with the interior. The principal articles of trade are wine, brandy, fruits, salt (of which a vast quantity is made along the coast), hardware, oil, provisions, soap, wool, and other French and colonial produce. Ships are fitted out for the whale, herring, and cod fisheries; and the mackerel and pilchard fisheries along the coast are actively plied.

Divisions and Chief Towns.—The department contains 1,684,588 acres, and is divided into five arrondissements, which, with their subdivisions and population, are as follows:—

Arronds.	Cantons.	Communes.	Pop. in 1861.
Nantes, . .	17	67	264,870
Ancenis, . .	5	27	49,835
Châteaubriant,	7	37	75,427
Paimbœuf, .	5	25	47,867
Savenay, . .	11	52	142,208
Total, .	45	208	580,207

In the arrondissement of Nantes the chief town is NANTES, which is also the capital of the whole department. *Chantenai*, situated on a high hill above the right shore of the Loire, has a population of 7252. *Clisson*, beautifully situated on the slopes of two hills at the junction of the Moine and the Sèvre-Nantaise, has a population of 2829, and manufactures of woollen cloth, cotton yarn, leather, and paper. On a rock above the town stand the majestic ruins of the ancient castle of Clisson, which for extent, construction, and beauty of site, has scarcely an equal among the castellated structures of France, while in historical associations it far outstrips them all. Some repairs have been lately made in order to arrest the progress of decay among these magnificent remains. *Chapelle-sur-Erdre*, on the slope of a hill near the left bank of the Erdre, has 2580 inhabitants. *Légé* is situated in the south of the department, near the right bank of the Logne, on a hill which commands a fine view of a rich well-cultivated country. The town, which suffered greatly in the civil war between the Vendéans and the Republicans, has 4488 inhabitants. On the Nantes road, at a short distance from Légé, a monument was erected in 1827 to the Vendean general Charette, which was demolished during the short frenzy of 1830. *Loroux-Bottereau*, a few miles east of Nantes, has 4212 inhabitants; within the town, in a spacious circular place surrounded by trees, a statue of Louis XVI. is erected. *Machecoul*, an ill-built town on the little river Falleron, and formerly the capital of the duchy of Retz, is 20 miles south-west from Nantes, and has 3727 inhabitants. This town was the scene of great cruelties and of some severe actions

during the Vendean war. *St.-Philbert*, 14 miles south-west from Nantes, is situated on the navigable river Boulogne, near its entrance into the Lake of Grand-Lieu, and has 3672 inhabitants. It stands in a fertile wine and corn country, and is a place of some trade in agricultural produce, timber, &c. *Vallet*, 5 miles north of Clisson, is situated on a height among rich vineyards, that yield the best wine of the department, and has 6476 inhabitants. *Vertou*, 5 miles south by east from Nantes, stands near the right bank of the Sèvre-Nantaise; population 6313.

Of the arrondissement of Ancenis, the chief town, *Ancenis*, is prettily situated among vine-clad slopes on the right bank of the Loire, 20 miles north-east from Nantes, and has a tribunal of first instance, a college, and 4628 inhabitants. The old castle of the dukes of Bethune, from the gardens of which there is a splendid view of the valley and islands of the Loire; the Ursuline convent, now a cavalry barrack; and the hospital—are deserving of notice. The steam-boats that navigate the Loire make Ancenis one of their stations. *Varades*, 8 miles east from Ancenis, stands on a high hill near the right bank of the Loire, and has 3368 inhabitants. It was before Varades that the Vendean army, after their defeat at Chollet by the Republicans, crossed the Loire in 1793.

In the arrondissement of Châteaubriant, the chief town, *Châteaubriant*, stands 37 miles north by east from Nantes, and has a tribunal of first instance and 4636 inhabitants, who manufacture common woollen stuffs, cordials, earthenware, tiles, and leather. *Moisdon*, on a hill near the right bank of the Don, has iron mines, iron forges, and 2609 inhabitants. *Nort*, 15 miles north from Nantes, is situated on the right bank of the Erdre, across which a stone bridge of six arches leads to the suburb of St.-Georges. The Erdre here becomes navigable for steamers which ply daily to and from Nantes. *Nort* is a busy town, with a population of 5665, who trade largely in wood, charcoal, and coal for the supply of Nantes, in iron, leather, cattle, &c. *Nozay*, 11 miles north from Nort, on the road from Nantes to Rennes, has 3692 inhabitants. *Rougé*, 5 miles north-west of Châteaubriant, gives name to important iron mines, and has 2705 inhabitants.

The arrondissement of Paimbœuf is named from its chief town, *Paimbœuf*, which stands 24 miles west of Nantes, on the left bank and near the embouchure of the Loire, and has a tribunal of first instance, a naval school, and 3509 inhabitants, who are chiefly engaged in the construction and repairing of ships, in the manufacture of cordage, tiles, and bricks, and in the fisheries and coasting trade. The town consists chiefly of one long street, which is built along the quays which line the river. It has a harbour formed by a well-constructed mole, and capable of admitting the largest ships. Steamers ply several times a day to Nantes. The population of Paimbœuf was nearly 10,000 before the French lost the West Indian Islands. *Bourgneuf-en-Retz*, 15 miles south from Paimbœuf, is situated on the Bay of Bourgneuf, opposite the isle of Noirmoutier, in a low marshy place, and has 2893 inhabitants, who are engaged in the fishery along the coast and in the manufacture of salt. *St.-Père-en-Retz*, 4 miles south from Paimbœuf, has 3086 inhabitants.

The arrondissement of Savenay is named from its chief town, *Savenay*, a small place of 2803 inhabitants, situated 22 miles north-west from Nantes, near the right bank of the Loire. The town, which has a tribunal of first instance, was the scene of a most bloody engagement (November 25, 1793) between the Republican army under Westermann, Kléber, Marceau, and Tilly, and the gallant Vendéans, who were entirely defeated. A monument in honour of the slain has been erected in the cemetery of Savenay. *Batz*, situated among the salt marshes on the sea-shore, where it has a good fishing harbour, is a well-built town with 3003 inhabitants. It has a handsome church with a tower, terminating in an elegant cupola 180 feet high, which serves as a landmark for sailors. *Blain*, near the right bank of the Isac, has 6781 inhabitants. The town was formerly defended by a strong feudal castle, erected by Alan, duke of Bretagne, in 1105. This fortress, which, with the exception of its towers, is still in tolerable preservation, subsequently belonged to the family of Clisson, from whom, by the marriage of Beatrix, daughter of the Constable Olivier de Clisson, it passed to the dukes of Rohan. *Coueron*, prettily situated on the right bank of the Loire, which here forms a commodious harbour for the repairing of vessels, has glass-works and 4709 inhabitants. *Croisic*, situated on the extremity of a small tongue of land that juts out into the Bay of Biscay, is an ill-built place with 2182 inhabitants, who are chiefly engaged in fisheries, the manufacture of salt and soda, and the coasting trade. On a dangerous ledge of rocks called *Le-Four*, off Croisic, a light-house is erected. *St.-Étienne-de-Mont-Luc*, 9 miles south-east from Savenay, has a population of 4783. *Guéméné*, situated on a hill near the right bank of the Don (which here begins to be navigable), at a distance of 22 miles north-north-east from Savenay, and has 4977 inhabitants. *Guérande*, an ancient town, situated about 3 miles from the sea and 25 miles west from Savenay, has an ecclesiastical college, two hospitals, and 8524 inhabitants, who manufacture great quantities of salt, linen, serge, cotton, and woollen yarn, &c. The town, built on the slope of a hill, is commanded by an old castle flanked with towers; it is surrounded by walls built of granite, and pierced by four gates situated at the cardinal points. The ditches which formerly surrounded this ancient fortress are now filled up and converted into shady walks. *Herbignac*, 18 miles north-west from Savenay, has extensive potteries and 3672 inhabitants. *St.-Nazaire*, a town of 10,845 inhabitants, composed chiefly of sailors, pilots, fishermen, and custom-house officers, is situated on the northern shore of the embouchure of the Loire. It has a light-house at the head of the mole which forms the harbour; its chief trade is in fish, corn, and salt. *Pont-Château*, on the left bank of the Brivé, which is navigable by means of the tide from this town to its entrance into the Loire a little above St.-Nazaire, has a corn-market, tan-yards, and 4449 inhabitants.

The department forms the see of the bishop of Nantes, is included in the jurisdiction of the Cour Impériale and Academy of Rennes, and belongs to the fifteenth Military Division, of which Nantes is head-quarters. It returns four members to the Chamber of Deputies.

(*Dictionnaire de la France ; Annuaire pour l'An 1866 ; Statistique de la France.*)

LOIRET, a department of France, formed out of the eastern part of the province of Orléanais, and a small part of Berry, lies between $47^{\circ} 29'$ and $48^{\circ} 20'$ N. lat., $1^{\circ} 32'$ and $3^{\circ} 5'$ E. long., and is bounded north by Seine-et-Oise and Seine-et-Marne, east by the department of Yonne, south by those of Nièvre, Loir-et-Cher, and Cher, and west by Eure-et-Loire. Its greatest length from east to west is 72 miles, and its average breadth from north to south is 42 miles. The area is 2578 square miles, and the population in 1861 was 352,757.

Surface and Hydrography.—The department is divided into two unequal parts by the Loire. The district situated S. of this river is part of the old district of Sologne [CHER], and presents a barren sandy soil, covered with heath, but here and there swelling into hills, which are planted with vines, yielding red and white wines of moderately good quality. The district N. of the Loire is composed of fertile and well-cultivated plains, separated by wooded hills, and diversified by extensive forests, rich meadows, and pasture lands. A chain of hills that forms part of the watershed between the Seine and the Loire traverses the department from S.E. to N.W., at no great distance from the right bank of the LOIRE, which river crosses the department in the same direction as far as Orléans, where it sweeps round to the south-west.

The department takes its name from the *Loiret*, a little river that rises all at once in full flood from a spring in the park of Château-de-la-Source, a few miles S.S.E. from Orléans, and flowing westwards enters the Loire on the left bank after a course of 7 miles. The waters of the Loiret never freeze, owing to the high temperature which they have on issuing from the earth, and to the shortness of their course. The *Duis*, a sluggish muddy stream, is the principal feeder of the Loiret; before its junction with the latter it enters a whirlpool by which part of its waters are generally absorbed, the remainder being conducted to the Loiret by a short canal. But at certain seasons of the year, when the waters of the Loiret are highest, a portion of them ascends the canal and enters with the Duis into the whirlpool, which is said to have an underground communication with the Loire. When the waters of the Loire, however, rise above their usual level, the whirlpool then, instead of absorbing the waters of either river, overflows and adds considerably to their quantity. The Loiret is navigable almost from its source; it drives the machinery of several mills and factories. The *Loing*, which receives the Ouanne and several other feeders, flows N. through this department from that of Yonne in its way to join the Seine. The north-western districts are drained by the Essonne, which flows N. and enters the Seine in the department of Seine-et-Oise. The department possesses great advantages from internal navigation by the Loire, and by the Canal d'Orléans and the Canal de Briare, which unite near Montargis, whence the Canal du Loing runs northward into the department of Seine-et-Marne, and passing Nemours, enters the Seine near Moret. The department is also traversed by the Paris-Orléans, the Orléans-Nantes, and the Orléans-Bourges railways.

Climate, Products, and Resources.—The climate is mild and healthy; the prevailing winds are the west and south-west.

The district north of the Loire is very productive of rye and other breadstuffs; but owing to the infertility of the Sologne district, the produce is little more than enough for the consumption. Yet the department has a most important trade in corn, which, however, is supplied from the great wheat districts of Beauce, Poitou, Anjou, and Lower Auvergne, and finds easy distribution from the great granaries of Orléans, by the means of transit before mentioned, to different parts of France. The quantity of oats grown is enormous, the annual exports amounting to 1,375,000 quarters. Saffron is extensively and profitably cultivated. Asparagus and other pot-herbs are raised in large quantities. About 22,000,000 gallons of wine are made annually, of which about one-fourth goes to the home consumption; most of the remainder is exported under the name of Vins d'Orléans, generally of ordinary quality; some is retained for making vinegar. Apple, pear, and all fruit-trees common to the north and centre of France are successfully cultivated, and a great quantity of preserves are made. The forests contain chiefly oak, beech, birch, elm, and chestnut. Cattle are of good breed, and also sheep, except in the Sologne, where they are small but well-fleeced. Bees are carefully tended; game, poultry, and fish are abundant.

Building and lime stone, marl, and potter's clay are the only minerals found.

The manufactures, except those of Orléans, are unimportant; but the commerce of the department is very extensive. The chief articles of trade are corn, flour, wine, brandy, vinegar, groceries, drugs, fruits and fruit-trees, peas and beans, chestnuts, cider, fish, honey, saffron, salt, wool, firewood, oak-staves, charcoal, cattle, &c.

Divisions and Chief Towns.—The department contains 1,649,933 acres, and is divided into four arrondissements, which, with their subdivisions and population, are as follows:—

Arronds.	Cantons.	Communes.	Pop. in 1861.
Orléans, . .	14	107	159,821
Pithiviers, .	5	98	61,653
Gien, . . .	5	49	52,465
Montargis, .	7	95	78,818
Total, . .	31	349	352,757

Of the arrondissement of Orléans, and of the whole department, the capital is ORLÉANS. The other towns are—BEAUGENCY: *Châteauneuf-sur-Loire*, which stands on the right bank of the Loire, E. of Orléans, and has woollen cloth and beet-root sugar factories, and 3197 inhabitants: *Cléry*, which is prettily situated near the left bank of the Loire, 9 miles S.W. from Orléans, and has 2765 inhabitants; this town is famous for its beautiful church of Notre-Dame, in the nave of which is a marble monument to Louis XI., who was buried here: *Jargeau*, which is 11 miles E. from Orléans, on the left bank of the Loire, here crossed by a fine bridge, and has a population of 2590. *Meung*, which is a well-built town, situated on the right bank of the Loire, 12 miles

by railroad W. by S. from Orléans, and has 3660 inhabitants, who manufacture leather, room-paper, and felt hats, and trade largely in flour; and *Patay*, a small town of 1208 inhabitants, 15 miles N.W. from Orléans, near which Joan of Arc defeated the English in 1429, and took Talbot prisoner.

The arrondissement of Pithiviers is named from its chief town, *Pithiviers*, which is situated on the slope and at the foot of a hill above the Euf (a feeder of the Seine, which lower down takes the name of Essonne), 25 miles N.E. from Orléans, and has a tribunal of first instance and 4778 inhabitants. The town, which is pretty well built, is famous for its almond-cakes and lark-pies. *Beaune-la-Rolande*, 8 miles S. from Pithiviers, near the Essonne, has a population of 1987.

The arrondissement of Gien takes its name from *Gien*, a well-built town, situated on the right bank of the Loire, which is here crossed by a handsome stone bridge of twelve arches, at a distance of 36 miles E.S.E. from Orléans. From the left bank of the river the view, comprising the bridge and the town, built along the slope of a hill, which is surmounted by the church of St.-Louis and a fine old castle in good preservation, is picturesque. Gien has a tribunal of first instance and 6528 inhabitants, who manufacture porcelain and leather, and trade in salt, corn, wine, saffron, and wool. *Briare*, 6 miles E. by S. from Gien, stands on the right bank of the Loire, at the point where the Briare Canal enters that river. It has a population of 3927, and a good trade in wine, wood, and charcoal. *Châtillon*, further up the Loire and on its left bank, has 3136 inhabitants. *Sully*, 13 miles W. from Gien, on the left bank of the Loire, has a population of 2527, and is remarkable for the castle of the lords of La Tremouille, which was restored by Henry IV.'s minister, Sully, who resided here after the death of his master.

In the arrondissement of Montargis, the chief town, *Montargis*, situated near a forest of the same name, in a plain, 40 miles E. by N. from Orléans, and at the junction of the canals of Briare, Orléans, and the Loing, which complete the navigation between the Loire and the Seine, has a college, tribunals of first instance and of commerce, and 8636 inhabitants. The town, which is pretty well built, has cloth factories, tanyards, paper mills, and a considerable trade in corn, saffron, hides, wool, cattle, &c. The most remarkable objects at Montargis are the church of La Madeleine, the old walls of the town, and the few remains of the extensive castle of Montargis, which was erected by Charles V. on a hill that commands the town. *Château-Renard*, situated 11 miles E. from Montargis, near the right bank of the Ouanne, has 2644 inhabitants. *Châtillon-sur-Loing*, 14 miles S.S.E. from Montargis, on the canal and river Loing, has a population of 2594. *Courtenay*, the cradle of the ancient house of Courtenay, is situated 15 miles E. by N. from Montargis, on the little river Clare, a feeder of the Loing, and has 2871 inhabitants. *Lorris*, formerly a favourite residence of the kings of France, and famous for its ancient charter of privileges, is situated 12 miles S.W. from Montargis, and has a population of 2008.

The department forms the see of the bishop of Orléans, is included in the jurisdiction of the Cour Impériale of Orléans, and Academy of Paris, and

belongs to the first Military Division, of which Paris is head-quarters. It returns three members to the Chamber of Deputies.

(*Dictionnaire de la France; Statistique de la France; Annuaire pour l'An 1866.*)

LOK, or LOKI, in Northern mythology, the name of an evil deity, corresponding to the Ahirman of the Persians, and the supposed source of all the evil with which the world is afflicted. In the great Norse poem of the Edda he is described as a huge serpent, encircling the earth, and as having produced Hela, or Death, the queen of the Infernal Realm.

LOKEREN. [FLANDERS, EAST.]

LOKMAN. There are various traditions about Lokmân, the supposed author of the collection of fables in Arabic, which still exists under his name. It has been conjectured that Lokmân and Æsop were the same individual. This supposition is founded on the close correspondence of the traditional accounts of the person, character, and life of Lokmân with those of Maximus Planides respecting Æsop.

The fables of Æsop have by no means the character of ancient and original Greek compositions. Many of them are strongly marked with an Oriental character. They bear a very striking resemblance to the Indian fables in the 'Panchatantra.' In the fables of Lokmân the same peculiar features frequently occur. Hence we may safely infer that both collections were originally derived from an Indo-Persian source, from whence certainly came the fabulous work attributed to Syntipas, who was no other than the Sindbad of the 'Arabian Nights.'

The fables of Lokmân show evident marks of a later and traditional origin. The moral or application is frequently misunderstood, or at least ill adapted to the apologue; a few ancient expressions had then become obsolete and are interpreted by words of more modern origin; and the language in general exhibits some slight deviations from grammatical accuracy, and approaches nearer to the modern Arabic idiom; as, for instance, in the use of the oblique case instead of the first case. The style is easy and flowing. The fables have often been reprinted for the use of those who are beginning to study the language, after the first edition, with a Latin interpretation by Erpenius, Leyden, 1615: the best and latest editions are by Cousin, Paris, 1818; Freytag, Bonn, 1823; Roediger, Leipzig, 1830; Schier, Dresden, 1831; Rasch, Copenhagen, 1832; and Derenburg, Berlin, 1850.

LOLIGO, the squid, or sea-pen cuttle-fish, very common on the British coasts. [SEPIADÆ.]

LO'LIUM, a genus of Grasses, containing a few species common in many parts of the northern hemisphere. There are two species which require notice. *L. perenne*, the common Ray-grass or Rye-grass of the farmer, one of the most valuable of our pasture grasses. *L. temulentum*, or Darnel, which grows not only in all parts of Europe, but in Japan, New Holland, China, and Monte Video. Darnel is remarkable as being the only well-authenticated instance of a plant belonging to the order of Grasses, in which narcotic or even deleterious properties have been found. The grains are said to produce intoxication in man, beasts, and birds, and to bring on fatal convulsions.

LOLLARDS, a religious sect which arose in Germany at the beginning of the fourteenth century,

and differed in many points of doctrine from the Church of Rome, more especially as regards the mass, extreme unction, and atonement for sin. The name seems derived from the German *lollen*, 'to sing lullingly,' and *hard*, a common affix. Hence, a Lollard was one who sang the praises of God. Lollard subsequently became a term of reproach for all heretics, who were supposed to conceal erroneous doctrines under the appearance of piety; and in England, at the close of the fourteenth century, it was given to the followers of Wycliffe. The term also extended into Scotland, and the Lollards of Kyle, in Ayrshire, excited great attention and were persecuted in the latter part of the fifteenth century.

LOMBARD, an ancient name in England for a banker, was derived from the Lombard merchants, the great usurers of the thirteenth century, who appear to have settled in England before the year 1274, and took up their first residence in a street of the city, still called from them Lombard Street.

LOMBARDIC ARCHITECTURE. This style of architecture may be considered the generic style which prevailed after the extinction of the Roman until the appearance of the Pointed or Gothic. It is the intermediate link between them. Though we are accustomed to regard the Lombardic historically as a distinct style, it was in fact only a further development of the system introduced during the decline of Roman architecture, which applied small orders merely as decoration, and introduced tiers of arches of which the piers form the solid supports of the structure.

Whether forming porticoes and galleries, or applied merely as decoration, these arcades are generally small in proportion to the building itself, and, instead of occupying the entire width of the front, or other elevation, are mostly inserted into distinct compartments of it, and are slightly recessed within the general face of the wall.

Among the other peculiarities of this style, that arising from small open galleries immediately beneath the cornice or roof is too remarkable to be overlooked, especially in gable fronts, where the arches of such galleries follow the slope of the roof itself, the columns being successively elevated one above another on steps (so that the base of those supporting the centre arch are above the lower arches), or else by placing the columns on the same horizontal line, and gradually increasing their height, as in the front of Pisa Cathedral. To this may be added the very prevalent custom of making an upper cornice or border of very small interlacing arches, or rather of mouldings producing that appearance. Pinnacles are of rare occurrence, and when introduced are generally low, and somewhat resemble pedestals. The cathedral of Novara, which belongs to the eleventh century, is one of the finest examples of the Lombardic architecture.

LOMBARDY and LOMBARD CITIES. The name of Lombardy, which is derived from that of the Longobards, its former possessors, has been applied in its widest sense, though with no very definite limitation, to that tract of country which the Romans called by the name of Cisalpine Gaul, and which includes the principal part of the basin of the Po. It consists chiefly of an immense plain, 200 miles long, and from 60 to 70 miles wide, from the Alps to the Apennines. [Po.]

The overthrow of the kingdom of the Longobards [LONGOBARDS] by Charlemagne did not destroy the political existence of that people. They retained their laws and institutions, their property, and their numerous and powerful nobility; they continued a nation and a kingdom, subject, however, to the monarchy of the Franks. Although on the one hand the nobles fostered a feudal spirit, yet on the other the towns began to rebuild their walls, which had been razed by the barbarians. The towns had retained the ancient system of municipalities, and the citizens elected their own magistrates.

After the deposition of Charles the Fat in 888, the crown of Italy was disputed for about seventy years among a succession of pretenders, Italians and Burgundians, until Otho I. of Saxony seized it with a firm hand, and was crowned at Rome by the Pope in 961. Otho and his successors resided chiefly in Germany; and the Lombard nobles and towns, though nominally dependent on the emperors, were in fact nearly independent.

Towards the middle of the eleventh century discord first began to break out in Milan and other cities between the various classes of the population. The lower nobility strove against those of higher rank, and the townsmen lent their aid in such a way as to increase their own municipal influence. On one occasion, in 1041, the plebeians or burghers rose against the whole class of nobles, owing to some insult offered by one of them to a common citizen; and the result was a conflict of three years' duration. In 1059 began the long struggle at Milan and in the rest of Lombardy on account of the married clergy. After a contest of many years, the archbishop of Milan came under the power of the Pope; and the papal discipline was enforced of not admitting any married man to orders.

In the great contest of the investitures, the Lombard cities first aided one side and then the other; and it was during this long struggle that the cities really established their independence, acknowledging no longer the imperial missi, or vicars. The citizens then began to elect a certain number of magistrates, whom they styled consuls, who administered justice and commanded the militia. The rural nobles inscribed themselves among the citizens, and came to reside, at least for part of the year, in the city, in order that they might participate in the political rights. The towns governed themselves in all essential matters, but they owed allegiance to the emperor in certain particulars. No sooner, however, had the towns secured their municipal privileges than they began to fight among themselves; and for a long period Italy was disgraced by brutal contests, in which nearly the whole of the towns were engaged. After a long series of these municipal rivalries and battles, the Emperor Frederick, in 1162, succeeded in quelling a war in which Milan had been especially conspicuous, and in destroying that city. But he so misused his advantage as to raise up a general spirit of resistance against him. In April, 1167, a secret conference was held by deputies of the various cities; and it was resolved to form a league for the common protection, and to assist the Milanese in rebuilding their city. After a severe struggle the towns succeeded against the emperor, and brought about the peace of Constance, in 1183. By this treaty the cities were confirmed in their independent administration;

they had the right of declaring war, of coining money, and other sovereign privileges, but acknowledged a sort of general obedience to the emperor in certain matters. No sooner, however, was this great contest ended than the towns recommenced their struggles with each other, and the contest between parties in each town began again. The annals of Italy for the thirteenth century consist of little else but details of these encounters. It has been said that notwithstanding all these feuds the Italian free cities prospered. The real truth is, that some of them flourished at the expense of the others. It is observed that a number of towns which are mentioned as being of importance in the eleventh century had disappeared in the thirteenth. We read of the glory and wealth of Milan and Florence, but we take no account of the depopulation and calamities of Lodi and of Pisa. Several causes contributed to maintain the wealth of the great Lombard cities during the middle ages—the extraordinary fertility of their territory, their manufactures, in which they were unrivalled in Europe, and the practice of their citizens of lending money at high interest throughout Europe, from whence the name of Lombard became synonymous with that of banker as well as usurer.

In the contests between the popes and Frederic II., in the middle of the thirteenth century, the Lombard cities were divided; and this division increased the anarchy which resulted from mutual jealousy and feuds. In 1260 Martino della Torre was chosen by the towns of Lodi and Novara as their 'signore, or lord. The fashion spread: Cremona chose for its lord the Marquis Pelavicino; Verona chose Martino della Scala; Mantua, the Count San Bonifazio; Ferrara, the Marquis of Este, &c. Martino della Torre having died in 1263, his brother Philip succeeded him as lord of Milan, Lodi, and Novara, to which he added Como, Vercelli, and Bergamo, which towns elected him as their lord. Thus the foundation was laid of that consolidation of Lombardy into one state which in after times was known by the name of the Duchy of Milan. The archbishop of Milan, Otho Visconti, became 'Perpetual Lord of Milan' in 1277; and his descendants, in the fourteenth century, ranked among the most powerful Italian princes. They extended their dominions not only over Lombardy Proper, but south and west of it. Gian Galeazzo Visconti received in 1395, from the Emperor Wenceslas, the title of 'Duke of Milan and Count of Pavia.' The charter of investiture included twenty-six towns and their territories, extending from the hill of Montferrat to the lagoons of Venice. Besides these he obtained also possession, by force or fraud, of Genoa, Lucca, Pisa, Siena, Perugia, Bologna, and other parts of Romagna. In the following century the duchy of Milan became circumscribed within narrower limits. The Venetians took the three provinces of Brescia, Bergamo, and Crema. The Swiss took possession of Bellinzona, and other valleys north of the Lago Maggiore. The duchy of Milan likewise lost its conquests south of the Po. The duchy of Milan, as it came into possession of Charles V., extended about 70 miles north to south from the Alps to the Po, and 60 miles east to west. Its principal cities were Milan, Pavia, and Cremona. Mantua formed a separate duchy until the war of the Spanish succession, when it was taken possession of

by the house of Austria, and annexed to the duchy of Milan. These two duchies constituted Lombardy Proper. The duchy of Milan, during a century and a half that it remained under the Spanish branch of the house of Austria, declined greatly from its former prosperity; but with its transfer to the German branch of that house, Lombardy began to recover its prosperity. By the peace of Campo Formio of 1797, which followed upon Bonaparte's great victories, and by the peace of Luneville, the states of Lombardy were detached from Austria. Milan and Mantua, or Lombardy Proper, were first constituted as a Cisalpine republic; then as an Italian republic, with Bonaparte as president; and were afterwards formed into a kingdom, of which Napoleon made himself king in 1805; and subsequently they were incorporated with Venice, Modena, and other states, into the 'Kingdom of Italy.' In 1814 the Austrian and allied forces occupied the kingdom of Italy, and the Emperor Francis again took possession of his former territories, which were confirmed to him by the congress of Vienna. The districts south of the Po were restored to their former sovereigns; Modena to its duke, and the Legations and Marches to the pope. The Emperor Francis then constituted the territory of Milan, Mantua, and Venice into a kingdom, styled Lombardo-Veneto, under the imperial sway of Austria. But the war of Italian independence in 1859, resulting in the treaty of Villafranca, deprived Austria of her Lombardic provinces, which were then annexed, with the exception of Venetia, to the new kingdom of Italy. The old designation is no longer preserved, but the country has been divided into the provinces of Bergamo, Brescia, Como, Cremona, Milan, Pavia, and Sondrio. Area, 8264 square miles; population, 3,039,055. [ITALY.]

LOMBEZ. [GERS.]

LOMBOK, an island of the Malay Archipelago, lying between 8° and 9° S. lat., and 115° and 116° E. long. It has the island of Bali on the west, and that of Sumbawa on the east. The form of Lombok is nearly square, its mean length and breadth being respectively 53 and 45 miles; area, 1668 geographical square miles, and the population, 250,000, mostly Mohammedans. The surface of the island is mountainous, and one of the loftiest peaks, Goensing Pindjanie, is said to rise to the height of 12,000 feet above the level of the sea. The island is populous and well cultivated. The plains are entirely devoted to rice, the hill sides producing coffee and maize. The chief port is Ampanan, on the western coast. It belongs to the Dutch.

LOMOND, LOCH. [DUMBARTONSHIRE.]

LOMONOSOV, MICHAEL VASILIEVITCH, was born in 1711, near Kholmogor, in the government of Archangel. His father was a serf of the crown, and by occupation a fisherman. The long winters were devoted by Michael to study, and though his stock of books was very small, he made diligent use of them; and being desirous of further instruction, made his way to Moscow, where he distinguished himself so much as to obtain patronage, and to be sent first to the University of Kiev, and afterwards to the Academy of St. Petersburg in 1734, applying himself to mathematics, physics, chemistry, and mineralogy. He was made an associate of the St. Petersburg Academy in 1741; in 1764, professor

of chemistry, and in 1760 rector of the university. He died April 4, 1765.

LONCHOPTERIS, a genus of fossil ferns established by M. Adolphe Brongniart. The species belong principally to the coal formation; but one, *Lonchopteris Mantelli*, is found in the Wealden deposits and in the green-sand.

LONCHURA, a genus of *Fringillidae*, or Finches, of which three species are found in the Deccan, two being restricted to the Ghauts.

LONDON, the capital of the British empire, lies upon both banks of the river Thames and on the hills which inclose the river valley, about 51 miles from its mouth. The centre of the dome of St. Paul's Cathedral, which stands nearly in the centre of what is strictly called the 'City,' is in lat. 51° 30' 47.59" N., and long. 0° 5' 48.2" W. London extends into four counties, Essex and Middlesex on the north, and Kent and Surrey on the south bank of the river.

What little our limited space permits us to say respecting this mighty city, the ancient *Londinium*, is arranged under the following heads:—

- | | |
|--|---|
| A. Government; | L. Educational and Literary Resources; |
| B. Divisions; | M. Charitable Institutions; |
| C. Population; | N. Police and Prisons; |
| D. Soil, Temperature, &c.; | O. Public Works and General Statistics; |
| E. Trade and Commerce; | P. Metropolitan Improvements; |
| F. Religion and Education; | Q. General Enumeration of Public Objects; |
| G. Newspaper Press, and Postal facilities; | R. Legal Courts; and |
| H. Objects of Interest; | S. History and Chronology. |
| I. London Worthies; | |
| K. Public Buildings of importance; | |

This classification will, it is hoped, enable the reader to refer more easily to any fact of special interest.

A. *Government*.—That vast congeries of independent districts which we call London is under the control of various administrative bodies—a circumstance which, until the last few years, interfered with every plan of general improvement, and prevented the due execution of many important public works. The City, properly so called, is one of the oldest municipalities in the United Kingdom. It is divided into twenty-six wards, each governed by an alderman, who is elected for life, and, by virtue of his office, is a magistrate. Each ward also sends representatives to the Common Council, which consists of 206 members, and forms with the lord mayor and aldermen a species of civic parliament for the regulation of the police, and the enforcement of social and sanitary laws. The lord mayor is chosen annually by the Livery from the aldermen, generally by seniority, and may be re-elected on the conclusion of his term of office. His residence is at the Mansion House; where, and at the Guildhall, are held the civic courts of justice. He is allowed an income of 8000*l.* a year to maintain the dignity of his office. The sheriffs of London are two in number, and are chosen annually from the Common Council. They are also sheriffs of Middlesex. The Corporation thus composed has a recorder, chamberlain, town-clerk, common sergeant, remembrancer, and other officers.

The freedom of the City was rarely attainable

in ancient times unless by servitude or patrimony. The exceptions were few, and those involved the payment of a heavy fine. Within the last quarter of a century, however, important relaxations have been introduced as to the admission to such a privilege, and in the present year (1866) the expense has been reduced to the insignificant sum of 2*l.* 18*s.* 4*d.* The City archives contain the names of a large number of royal and other illustrious personages on whom the honour has been conferred. At present, the freedom of the City may be obtained—1st. By servitude, being bound to a freeman, according to the custom of the City, and served duly and truly seven years. 2nd. By patrimony: that is, being the son or daughter (unmarried or a widow) of a freeman, born after the admission of the father, and having attained the age of twenty-one years. 3rd. Gift of the City, or honorary freedom. 4th. By redemption or purchase. The admission under this head is as follows:—Persons on the parliamentary register of voters for the City are admitted upon their application to the chamberlain (either with or without the interference of a company), and without the usual presentation to the court for an order. Persons not on the parliamentary register, but who are 10*l.* householders, and rated to the police and other rates, upon producing a certificate (on their application to the chamberlain) from the beadle or other authority of their ward that they are so rated, are admitted (with or without the interference of a company) upon the chamberlain presenting their names to the court, and obtaining an order for their admission. All the foregoing pay 5*s.* on their admission, which fee goes to the Freeman's Orphan School. Persons who hold premises, or carry on their business, not having the qualification of either of the two cases before mentioned, are admitted (with or without the interference of a company) upon a fine, including the 5*s.* to the Freeman's Orphan School, of 2*l.* 18*s.* 4*d.* Lastly, persons neither holding premises, nor carrying on business within the City or its liberties, and wishing to become freemen, on their application, can be admitted (either with or without the interference of a company) on the chamberlain obtaining an order of the court, on their application. The fine in this case, including the 5*s.* to the Freeman's Orphan School, is 2*l.* 18*s.* 4*d.* The sons of aliens, born in England, &c., are now admitted the same as natural-born subjects.

Westminster is governed by a steward and a high bailiff; Marylebone, Chelsea, St. Pancras, Finsbury, Islington, and Lambeth, by vestries, whose members are elected by the ratepayers. Southwark was granted to the citizens by charter 1 Edward III., in order that they might have some control over the thieves who plundered the citizens and then passed into Southwark. It is governed by a high bailiff appointed by the citizens. It constitutes the ward of Bridge Without, and sends a representative to the court of aldermen.

The management of the streets, drains, and buildings of the metropolis was formerly in the hands of various local boards. To remedy the confusion, misgovernment, and other evils that resulted from such a conflict of authorities and interests, an Act of Parliament was passed in 1855 (18 & 19 Vict. c. 14) constituting a body of forty-five persons, to

be elected by the ratepayers, with power of levying rates, and effecting metropolitan improvements, under the title of the Metropolitan Board of Works. These elect one of their own number to act as chairman. They serve for a period of three years. This Board has built for its own use a handsome set of offices on the site of Berkeley House, Spring Gardens, at the cost of 15,000*l*. The City sewers are intrusted to the management of a commission appointed from the members of the Common Council under the Act 11 & 12 Vict. c. 163, and 14 & 15 Vict. c. 91. In 1866 the number of commissioners was increased to 100. [METROPOLITAN LOCAL MANAGEMENT.]

For parliamentary purposes London is divided into eight boroughs, whose population, registered electors, and number of representatives were, according to the latest returns (1866), as follows:—

Borough.	Estimated Population in 1866.	Electors.	Members Returned.
City of London,	104,908 ...	15,534 ...	4
City of West- minster, }	261,389 ...	12,546 ...	2
Marlybone, .	473,091 ...	23,588 ...	2
Finsbury, . .	423,560 ...	25,461 ...	2
Tower Hamlets,	710,179 ...	34,115 ...	2
Southwark, . .	204,872 ...	11,631 ...	2
Lambeth, . . .	319,403 ...	27,754 ...	2
Greenwich, . .	160,086 ...	9,805 ...	2

By the bill for the redistribution of seats, introduced by Earl Russell and Mr. Gladstone in the session of 1866, it was proposed to give two members to the important parishes of Chelsea and Kensington, whose united population amounts to 259,886. It was also proposed to make two divisions of the Tower Hamlets, and give two members to each.

Under this head reference may be made to the City Companies, seventy-five in number, relics of the old trading guilds or fraternities, which in mediæval times were all-powerful within the city in their respective occupations, and with whose privileges the most despotic of our monarchs did not dare to interfere. The names of some of them refer to branches of trade that have long ceased to exist; they now possess but little influence, and are chiefly important as social and charitable corporations; only forty of them have halls.

Twelve of the wealthiest and most ancient are known as the Great Livery Companies. They are—the Mercers, hall and chapel in Cheapside, between Ironmonger Lane and Old Jewry; the Grocers, hall in Princes Street, built 1798–1802; the Drapers, hall and gardens, Throgmorton Street; the Fishmongers, hall, Adelaide Place, London Bridge, built in 1831; the Goldsmiths, hall in Foster Lane, Cheapside, built by Hardwick in 1835; the Skinners, Dowgate Hill; the Merchant Taylors, hall in Threadneedle Street, built in 1667; the Haberdashers, hall in Gresham Street, rebuilt in 1835; the Salters, hall in St. Swithin's Lane, opened in 1827; the Ironmongers, hall in Fenchurch Street, built in 1748; and the Vintners, hall in Upper Thames Street; and the Clothworkers, hall in Mincing Lane. Of the other companies the most important are—the Apothecaries, whose hall (1670) is in Water Lane, Blackfriars; and the Stationers, Stationers' Hall Court, Ludgate Hill.

The Guildhall, belonging to the Corporation of London, was begun in 1411, finished in 1483, and partially destroyed by the great fire in 1666. It was repaired and the walls heightened in 1669, and a frontage built in 1789, from G. Dance's design. A new and handsome roof has just been completed, and at the present time (1866) extensive restorations and improvements are being effected, which, when carried out, will render the hall second only to that at Westminster. The Mansion House was erected, also from Dance's designs, in 1739–41. The principal room is the Egyptian Hall. Another civic memorial is Temple Bar, built by Sir Christopher Wren in 1670.

The revenues of the corporation amounted in the ten years 1856–1865 to 3,183,528*l*. 9*s*. 3*d*. Of that sum 1,067,722*l*. was received for rents; 169,109*l*. 13*s*. 11*d*. for tolls and rents from the several markets; 576,684*l*. 9*s*. 1*d*. for coal and corn duties and stamping weights and measures; the bequests made to the City during the same period amounted to 1356*l*. 13*s*. 4*d*., and the brokers' rents and fees, 46,343*l*. 15*s*. The fees on freedoms, Mayor's Court, and judiciary fees, show that 21,273*l*. was received in that direction. The interest arising from the sale of premises, the Finsbury Accumulation Fund, the City Accumulation Fund, and East India Debentures, 34,919*l*. 9*s*. 4*d*.; reimbursement on account of prisons, 30,731*l*. 1*s*. 1½*d*.; and reimbursement on account of criminal prosecutions, 14,482*l*. 11*s*. 1*d*. There were also reimbursements on account of the Royal Reception Committee, and the Royal Entertainment Committee, amounting to 4230*l*. In addition to these sums there were sundry and casual receipts, including sale of old materials, income duty deducted, surplus profits of the office of chamberlain and comptroller, reimbursement from Lord Mayor's Court Fund, sale of old stores and market reimbursements, amounting in all to 81,728*l*. The loans were as follows:—Loans raised for Metropolitan Cattle Market, 20,000*l*.; loans raised to meet temporary loans outstanding, 370,000*l*.; loan raised for Pauper Lunatic Asylum, 43,500*l*.; Billingsgate Market, advance repaid, 9340*l*.; Gresham Fund, advance repaid, 6972*l*.; Blackfriars Bridge Repairing Fund, advance repaid, 4989*l*. 15*s*. 5*d*.; transfers from reserve and sinking funds, 135,000*l*.; sale of premises in Finsbury, Giltspur Street, Great Tower Street, Upper Thames Street, and Clerkenwell, 32,914*l*. 14*s*. 2*d*.; sale of securities to meet outstanding bonds, 158,816*l*.; produce of Metropolitan Railway shares, 257,437*l*. 10*s*.; and sale of East India stock, 68,262*l*. 7*s*. 6*d*. The last item in the ten years' receipts is sundry balances brought to credit of City's cash, 27,774*l*. 14*s*. 6*d*.; making up the grand total of 3,183,528*l*. 9*s*. 3*d*. The expenditure for the same period amounted to 3,209,859*l*. 5*s*. 6*d*., showing an excess of expenditure over the receipts of the ten years of 26,330*l*. 16*s*. 3*d*.

B. Divisions.—The City, including the liberties, or the districts into which the municipal franchises and privileges extend, is divided into two portions: London within the Walls, and London without the Walls—a distinction which exists no longer except in name. The original wall of the City began at a fort which in part occupied the site of the present Tower of London, whence it was carried northward through the street now called the Minories to Aldgate; thence

diverging to the west it crossed Bishopsgate church-yard to Cripplegate; then southerly to Aldersgate; thence to the north of Christ's Hospital; turning directly south to Ludgate, it then again took a westerly course to New Bridge Street, and accompanied the line of the Fleet River to its junction with the Thames, where another fort marked its termination. The space within the line thus described comprehends London within the Walls, and includes 98 parishes, covering 370 acres. London without the Walls consists of 11 parishes, extending over 230 acres; besides inns of court, hospitals, and other extra-parochial districts locally connected with the above-named parishes. The whole of London Bridge is held to be within the City, together with a plot of ground at the south end of the old London Bridge on the Surrey shore, and called the Bridge-foot. The borough of Southwark, and a part of the manor of Finsbury, are for certain purposes considered to be within the jurisdiction of the City. This, however, forms but a small part of the metropolis, or of London in the large sense of the term, which comprehends the city of London within and without the walls, the city of Westminster, the borough of Southwark, and the parliamentary boroughs of Finsbury, St. Marylebone, the Tower Hamlets, and Lambeth; while, according to the limits adopted by the registrar-general, it also includes numerous other populous and flourishing districts. Taken in its largest sense, then, London now comprises:—

North of the River.

The *City Proper*, bounded on the N. and E. by the borough of Finsbury, on the W. by the city of Westminster, to which Marylebone adjoins on the N.

In the W. there are the districts of Pimlico, Brompton, Chelsea, Kensington, Bayswater, and Notting Hill.

In the N.W., St. John's Wood, Portland Town, St. Pancras, Somers Town, Kentish Town, Camden Town, Islington, Holloway, and Highbury, with Hampstead and Highgate on the ridge beyond.

In the N.E., Kingsland, Stoke Newington, Dalston, Hackney, and Clapton.

In the E., Bethnal Green, Whitechapel, Stepney, Limehouse, Poplar, Old Ford, Bow, and Bromley.

South of the River.

In the E., Southwark, familiarly known as 'the Borough,' and including the river-side districts of Bermondsey and Rotherhithe.

In the W., Lambeth, with the adjacent districts of Kennington, Walworth, Newington, Wandsworth, and Camberwell, extending to Dulwich,ulse Hill, Herne Hill, Brixton, and Battersea.

C. Population.—According to the census returns of 1861, the population of the metropolis amounted to 2,803,921 persons, living in 360,237 houses, spread over 78,027 acres of ground, or about 121 square miles.

The average number of births weekly is 2052, of deaths 1412, showing an increase of population amounting to 640 weekly, which from other sources is swelled to about 1000. The registrar-general, therefore, calculates that in 1865 the population of London had increased to 2,993,513 persons, and that in 1866 it must amount to 3,037,991. The average

annual death-rate speaks favourably as to the general healthiness of London, being only 25 in 1000; and when the new drainage system and other sanitary improvements are fully in operation, we may expect even this moderate rate to be largely reduced.

	1861.	1862.	1863.*	1864.	1865.
Births, ...	96,389	97,418	103,897	102,187	106,722
Deaths, ...	65,001	66,950	72,346	77,723	73,460
Excess of Births over Deaths, }	31,388	30,468	31,551	24,464	33,262
	* 53 weeks.				

The growth of the metropolis during the last decade has been extraordinary, surpassing the increase for a similar period of any other metropolitan city in ancient or modern times. Since the commencement of the present century, the decennial returns of the population have been as follows:—

1801, ...	958,863
1811, ...	1,138,815
1821, ...	1,378,947
1831, ...	1,654,994
1841, ...	1,948,369
1851, ...	2,362,236
1861, ...	2,803,921

By the census of 1861, the population of the City proper was only 112,247; while including that with the entire metropolis, the number was 2,803,921—or *twenty-five times* as great as the former! It may here be remarked, that the population of the City is becoming smaller every year, on account of the substitution of public buildings, railway stations and viaducts, and large warehouses in place of ordinary dwelling-houses. Fewer and fewer people *live* in the city. In 1851, the number was 127,869; it lessened by more than 15,000 between that year and 1861; while the population of the *whole* metropolis increased by as many as 440,000 in the same space of time.

Previous to the census of 1801 it was impossible to arrive at any authentic estimate of the population of London. It was computed by Graunt in 1661 to be 384,000, which number would probably be increased to 460,000, if we added the population of Westminster, Lambeth, Stepney, and other neighbouring places. Gregory Ling, a careful writer, thought that the population of the City and the out parishes amounted in 1696 to 527,560. Between 1740 and 1750 the population is known to have decreased, and at no time during the first half of the last century did it make any rapid increment. Dr. Price supposed that in 1777 it was 543,420, but there is reason to believe that this estimate is too low by 100,000.

D. Soil, Temperature, &c.—London stands, for the greater portion of its area, on a bed of clay from 100 to 200 feet thick, known as the 'London clay,' in the centre of the great chalk basin extending from Berkshire to the east coast. The prevailing wind is the S.W., and there are few places in the kingdom where less rain falls. Taking a series of twenty-one years, from 1840 to 1860, the mean temperature of the air was 49°·2 Fahr., the highest annual mean during that period being 51°·3 in 1846, and the lowest 46°·9 in 1855. The mean pressure of the air during nineteen years was 29·778 inches. The mean annual rain-fall in the same series of twenty-

one years was 23·95 inches, ranging from 17 inches in 1858 to 34·4 in 1852. The mean annual rain-fall, however, extending the computation over forty-five years, was 25·3 inches.

The following results were obtained at Greenwich for 1865:—

	Mean Temperature.	Mean of Barometer. Inches.	Rain in Inches.
Winter, . .	36·5 ...	29·616 ...	6·1
Spring, . .	50·2 ...	29·917 ...	7·2
Summer, . .	62·5 ...	29·860 ...	6·5
Autumn, . .	46·0 ...	29·739 ...	9·2

For the year, 50·3 ... 29·783 ... 29·0

The weight of vapour in a cubic foot of air in the same year was calculated to be 3·6 grains.

E. Trade and Commerce.—Although the exports from Liverpool are much in excess of those of London [LIVERPOOL], the shipping and import trade at the metropolitan port is unsurpassed in the world. The following tables, compiled from the latest official returns, give all necessary information on these subjects, and show the reader the vast extent of the commercial relations and the immense resources of the British capital.

The number of vessels registered as belonging to the port of London in 1866 was as follows:—

	Vessels.	Tons.
Sailing—under 50 tons,	770 ...	26,877
“ above “	1,793 ...	828,698
Steam—under “	181 ...	5,238
“ above “	543 ...	297,671
Total, . .	3,287 ...	1,158,484

The number of entries in 1865 was—

	Vessels.	Tons.
Coastwise—		
Sailing—British, . .	11,115 ...	1,343,589
“ Foreign, . .	3 ...	927
Steam—British, . .	3,805 ...	1,720,864
“ Foreign, . .	— ...	—
From the Colonies—		
Sailing—British, . .	2,061 ...	917,729
“ Foreign, . .	205 ...	118,039
Steam—British, . .	99 ...	64,905
“ Foreign, . .	1 ...	240
From Foreign Countries—		
Sailing—British, . .	2,781 ...	624,902
“ Foreign, . .	3,498 ...	826,796
Steam—British, . .	2,372 ...	875,193
“ Foreign, . .	593 ...	218,338
Total, . .	26,533 ...	6,711,522

The clearances in the same year were—

	Vessels.	Tons.
Coastwise—		
Sailing—British, . .	6,284 ...	433,362
“ Foreign, . .	38 ...	4,267
Steam—British, . .	1,713 ...	684,235
“ Foreign, . .	— ...	—
To the Colonies—		
Sailing—British, . .	1,185 ...	719,147
“ Foreign, . .	42 ...	21,712
Steam—British, . .	77 ...	45,590
“ Foreign, . .	— ...	—

To Foreign Countries—	Vessels.	Tons.
Sailing—British, . .	1,372 ...	251,160
“ Foreign, . .	3,015 ...	750,747
Steam—British, . .	1,840 ...	630,462
“ Foreign, . .	562 ...	208,991

Total, . . 16,128 ... 3,749,673

The imports of cotton, wheat, flour, dye-stuffs, hemp, jute, palm oil, copper ore, lead, saltpetre, and molasses, are greater at Liverpool than London: while in the articles flax, flax-seed, and iron, Hull takes the lead, and Southampton as respects silk and eggs. But in most other articles London has the precedence, and of some enjoys almost an exclusive monopoly.

The following table of the imports of some of the principal articles of foreign and colonial produce, in 1864, shows at once the relative importance of the trade of the port of London with that of the rest of England and Wales:—

	Total imported into England and Wales.	Total into London alone.
Animals, living—		
Oxen, bulls, and cows,	174,226 ...	117,008
Sheep and Lambs, .	478,178 ...	339,511
Cocoa, . . . lbs.,	7,792,259 ...	4,511,810
Corn—		
Wheat, . . . cwt.,	13,522,237 ...	3,531,900
Barley, . . . “	3,475,166 ...	995,111
Oats, . . . “	5,526,119 ...	4,944,848
Flour, ...	3,367,215 ...	686,655
Cotton manufactures, value, . . . }	£803,601 ...	£476,999
Indigo, . . . cwt.,	76,214 ...	65,172
Currants, . . . “	757,807 ...	490,275
Lemons & oranges, bshls.,	1,200,107 ...	657,196
Raisins, . . . cwt.,	309,713 ...	240,144
Hemp, . . . “	803,616 ...	245,409
Jute, . . . “	1,751,553 ...	1,113,413
Hides—dry, . . . “	267,344 ...	190,611
“ wet, . . . “	663,711 ...	273,259
“ tanned, lbs.,	6,265,871 ...	3,264,807
Mahogany, . . . tons,	39,940 ...	22,520
Oil—cocoa-nut, cwt.,	375,218 ...	369,309
Butter, . . . “	931,554 ...	439,963
Cheese, . . . “	712,323 ...	232,498
Eggs, great hundreds,	2,794,004 ...	677,063
Rice, . . . cwt.,	3,185,308 ...	1,507,522
Silk—raw, . . . lbs.,	5,655,401 ...	1,184,037

Flannel, carpets, &c., 6,853,878 " ...	653,272	
Hosiery and other } woollen goods, } —	256,258	

In addition to the exports of British produce, a very large quantity of foreign and colonial goods are re-exported from London to every part of the civilized world. Amongst the principal articles, in 1864, were—cocoa, 1,658,905 lbs.; coffee, 72,578,252 lbs.; cotton, raw, 311,045 cwts.; currants, 88,446 cwts.; raisins, 40,471 cwts.; hemp, 295,446 cwts.; hides, 150,420 cwts.; oil (cocoa-nut), 206,036 cwts.; quicksilver, 1,704,976 lbs.; pepper, 10,616,449 lbs.; rum, 1,731,104 galls.; brandy, 613,270 galls.; spirits unenumerated and mixed in bond, 901,188 galls.; tea, 26,621,583 lbs.; wine, 1,806,762 galls.; wool, 35,727,776 lbs.

The customs revenue received at the port of London is usually as large an amount as the aggregate receipts of every other port in the United Kingdom. The following are the exact totals during the last six years:—

In 1860, ...	£11,781,819
In 1861, ...	11,905,555
In 1862, ...	12,156,115
In 1863, ...	11,974,397
In 1864, ...	11,491,412
In 1865, ...	10,942,913

The decline in the last three years is entirely owing to the great reductions which took place in the customs duties on sugar, tea, wine, and other articles, and not to any decrease in the trade of the port, which year by year continues to expand. One-fourth of the whole tonnage of England belongs to the metropolitan port.

F. Religion and Education.—In 1865 the proprietors of the *Nonconformist* newspaper instituted a most searching inquiry as to the accommodation for public

worship provided by the different religious denominations in London. The returns are admitted on all hands to be substantially accurate, and from them we gather the following rather startling facts. In 1851 the Established Church provided accommodation for 409,834 persons, out of a metropolitan population of 2,362,230. This provision had been increased 25 per cent. in 1865—or in other words, about eight new churches had, on the average, been annually erected by the Established Church since 1851; but as the population has been growing at the rate of 45,000 yearly, the Church of England is at present only able to make provision for the spiritual wants of 17 per cent. of the inhabitants of the metropolis. It is true, that by means of the bishop of London's fund, which already amounts to a quarter of a million, and other agencies, great efforts are now being made to cope with such an appalling amount of religious destitution; but at present it is still doubtful whether the Church in London has satisfactorily fulfilled the mission which the State has intrusted to her. With two exceptions, each of the ten principal Protestant denominations has made greater proportional progress in London during the past fourteen years than the Established Church. The following table will indicate their respective positions:—

	1851. Sittings.	1865. Sittings.	Increase since 1851.	per cent.
Congregationalists, ...	100,436	130,611*	30,175	30
Baptists, ...	54,234	87,559	33,325	61
Wesleyans, ...	44,162	52,454	8,292	19
U. Methodist Free Churches, 4,858	13,422	8,564	176	
Methodist New Connection, 984	6,667	5,683	577	
Primitive Methodists, ...	3,380	9,230	5,850	173
Calvinistic Methodists, ...	800	3,790	2,990	474
Church of Scotland, ...	3,886	5,116	1,250	32
English Presbyterians, ...	10,065	12,952	2,887	28
United Presbyterians, ...	4,280	4,860	580	13

* Including the few Countess of Huntingdon's chapels.

The remaining denominations stand as follow:—

	1861. Sittings.	1865. Sittings.	Increase.	Decrease.
Society of Friends, ...	3,157	3,179	22	—
Unitarians, ...	3,300	4,430	1,130	—
Plymouth Brethren, ...	230	3,360	3,130	—
Foreign Lutherans, ...	3,002	3,502	500	—
Roman Catholics, ...	18,230	31,100	12,870	—
Catholic and Apostolic } Church, ...	2,700	5,020	2,320	—
Latter Day Saints, ...	2,640	1,590	—	1,110

In 1851 the Established Church provided 59 per cent. of the entire religious accommodation, and the Dissenting denominations 41 per cent. During the last fourteen years the former has been increased 25 per cent., and the latter 40 per cent., so that the relation of the two bodies to the entire population is now—Church, 56 per cent.; Dissenters, 44 per cent.

The net result of the efforts of *all* the religious bodies in London to meet the permanent wants of its teeming population is, in the smallest compass, as follows:—

	No. of Places of Worship.	Sittings.	Population.	Proportion per cent. accommodated.
1851, ...	1,097 ...	698,549 ...	2,362,236	30.2
1865, ...	1,316 ...	917,895 ...	3,015,494*	30.4
Increase, 219 ...	219,346 ...	653,258	—	.2

* The registrar-general's estimate for the middle of 1865.

There has thus been an increase of accommodation

in fourteen years of about 31 per cent. Had the addition been three-fold, it would only have sufficed to meet the increase of population. Taking only 52 per cent. of the number of inhabitants (Mr. Horace Mann's estimate) as the maximum to be provided for, the following result is obtained:—

Number of persons unprovided for in London	
in 1851, ...	669,514
Ditto in 1865, ...	831,387

Increased deficiency, ... 161,873

It would thus appear that if all the persons in London who are not physically disqualified, or kept away for any legitimate reasons, were to attend church or chapel at the same time, 52 per cent., or more than one-half the population, would be shut out for want of room: and 161,873 more persons than in 1851 would now be excluded, notwithstanding the considerable augmentation of places of worship. Unfortunately, however, the existing accommodation is by no means well used in many parts of the metropolis, and it is estimated that 300,000, or 33 per cent., of the sittings are unoccupied at the most numerous attended services. No doubt, if the existing accommodation could be better distributed, it would be more used. This matter is put in a very clear light by means of the Summary Table published by the *Nonconformist*. The following will illustrate the great disparity between different metropolitan parishes, and it will be seen that the poorest are invariably the worst supplied:—

	Proportion per cent. of Population accommodated.		Proportion per cent. of Population accommodated.
City of London, 104'4		Shoreditch, ...	17'2
Hampstead, ...	52'7	Bermondsey, ...	19'
St. Martin's, ...	45'4	Stepney, ...	20'2
Hackney, ...	45'4	St. Luke's, ...	21'8
Wandsworth, ...	41'7	Bethnal Green, ...	23'3

The space we have already devoted to this part of our article precludes us from pursuing this interesting subject further, and we can only add that in the preceding estimates we have not included the many indirect forms in which religious zeal has found expression in London—such as the City and other Missions; the Ragged School Union; the Scripture Readers' Society; the Bible Women; and the very large number of Sunday Schools—by which many thousands of the poorer classes, who could never be induced to enter a regular place of worship, are systematically brought under the influence of Christianity.

London became the seat of a diocese about 600–10, when Ethelbert, king of Kent, founded the East Minster on the site of St. Paul's. The diocese comprises London and Middlesex, with small portions of Essex, Kent, and Surrey immediately adjoining, in the province of Canterbury. The benefices number about 350. The bishop is provincial dean of Canterbury, and dean of the Chapels Royal. He ranks next to the archbishop, and has an income of 10,000*l.*, with a seat at London House, St. James' Square, a palace at Fulham, on the Middlesex bank of the Thames, and the patronage of about 109 livings. The dean's income is 2000*l.* The dean and chapter hold the patronage of 46 livings.

G. London Newspaper Press, and Postal Facilities.—As the newspapers issued in the metropolis are conducted by the highest talent, and possess the most authentic sources of information, they necessarily exercise a great influence on public opinion throughout the kingdom, and, indeed, in every civilized country. According to the most reliable estimates, the present aggregate issue of newspapers published in London is—

Daily, ...	800,000
Weekly, ...	2,350,000

The combined annual issue, therefore, approximates to 220 millions.

Of the daily newspapers, 12 are published in the morning, and 10 in the evening. There are 186 published weekly, and 55 at various dates. Besides these there are 548 periodicals of all kinds regularly published in the metropolis.

The London Postal District, to which special rules relate, includes every town and village within twelve miles of the General Post-Office. This vast area (having nearly 4,000,000 inhabitants in 1866) now contains about 1100 post-offices, of which the majority are receiving-houses, and the rest letter-pillars. Of this total number about 400 are Money-order Offices, the whole of which (with a very few exceptions) have within a recent period been made Post-Office Savings Banks also.

There are ten Sub-postal Districts, each of which has a name, an initial abbreviation, and a chief office. They are as follows:—E.C., Eastern Central; W.C., Western Central; N., Northern; N.E., North-Eastern; E., Eastern; S.E., South-Eastern; S., Southern; S.W., South-Western; W., Western; N.W., North-Western.

The 1100 receiving-offices and letter-pillars are pretty equally distributed in these ten districts. The use of the district system is this: If a letter, arriving from the country, has on the outside the district initials as well as the address, it has a fair chance of earlier delivery; and if sent from one part of London to another, the chance of acceleration is still greater. The reason for this is, that much of the sorting is effected at the ten chief district offices, if the initials are given, to the great economizing of time; this cannot be done if they are omitted. Letters are sent out for delivery in London eleven times a day, namely, at 7, 9.30, 11, 12, 1, 2, 3, 4, 5, 6, and 7 o'clock. The whole of these deliveries apply to all the streets within three miles of the General Post-Office. Seven of them apply within the four-mile circle; five within the six-mile circle; and three within the twelve-mile. A letter posted in any part of the metropolis before four o'clock in the afternoon is (if properly initialed) delivered anywhere within the twelve-mile circle the same evening; if posted before six o'clock, it will be delivered the same evening within the six-mile circle. The number of letters now delivered in London annually is nearly 200,000,000, or a fourth of the number delivered in the whole of the United Kingdom.

H. Objects of Interest.—So wealthy and powerful a city, the metropolis of a mighty empire, and the commercial centre of the world, is necessarily rich in all those objects of art and science, of national splendour and historical interest, which attract the admiration of the stranger, and afford a constant

source of pleasure and profit to the critic. A volume might well be devoted to their enumeration, and in these pages we can do no more than point out what everybody should not fail to see, leaving out of the question all that everybody should see. The artist and connoisseur, then, must not neglect the National Gallery, which contains a noble collection of the masterpieces of the greatest painters; the Queen's private gallery at Buckingham Palace; the works of art at South Kensington; the Bridgewater and Grosvenor galleries; the Duke of Devonshire's gallery; Lord Lansdowne's, Lord Ashburton's, Lord Dudley's, Mr. Baring's, and Miss Burdett Coutts' collections; and the Dulwich Gallery. For the productions of contemporary artists, they must repair to the Royal Academy of Arts, the British Institution, and the exhibitions of the different societies of painters.

The sculptor will find ample material for thought and study in the fine specimens of ancient marbles at the British Museum, in the sculpture at St. Paul's and Westminster Abbey, the admirable collection of casts at the Crystal Palace, and Flaxman's models at University College.

The architect in every part of London will discover much to admire, and examples of the various orders on the grandest scale. Such are the Norman chapel in the Tower; Westminster Abbey; Westminster Hall; Temple Church; the Guildhall Crypt; and Lambeth Palace: Inigo Jones' works—The Banqueting House, Whitehall; St. Paul's, Covent Garden; the Water Gate anciently belonging to York House; Lincoln's Inn Chapel; and the Piazza, Covent Garden: Sir Christopher Wren's churches—especially St. Paul's Cathedral; St. Stephen's, Walbrook; St. Mary-le-Bow; St. Bride's, Fleet Street; St. Magnus', London Bridge; St. James', Piccadilly; and St. Michael's, Cornhill. We may also name Sir Charles Barry's *chef d'œuvre*, the new Houses of Parliament; St. Margaret's Church, Wells Street; the Mansion House; Burlington House; Somerset House; London, Waterloo, and Westminster bridges; the railway bridges; the Grosvenor, Charing Cross, Langham, Cannon Street, Great Northern, Great Western, Westminster Palace, and London Bridge hotels; the Bank of England; St. Stephen's Church, Rochester Row; the Reform and Carlton Club-houses; the British Museum; All Saints Church; Cavendish Square; Lincoln's Inn; Goldsmith's Hall; the Treasury, Whitehall; Bridgewater House; and the palatial buildings recently erected by various assurance societies, bankers, and merchants.

To the antiquary we may recommend an examination of the Tower, Westminster Abbey, the Chapter House (about to be restored by G. G. Scott), the London Stone and remains of old London Wall, St. John's Gate (Clerkenwell), Lambeth Palace, St. Mary Overy's, and the Temple Church.

The pleasure seeker will find enough to content him in the various theatres and music halls, the Horticultural Gardens, Kew Gardens, Hyde Park and Rotten Row, Kensington Gardens, the Zoological Gardens, Regent's, Victoria, and Battersea Parks, the Thames Tunnel, the *Times* and *Daily Telegraph* newspaper offices, Barclay & Perkins' brewery, the cricket ground of the famous Marylebone Club, Cremorne Gardens, the Dulwich Gallery, Tussaud's

Exhibition, Greenwich Park, and, above all, the Crystal Palace.

The principal theatres of the metropolis are—Her Majesty's, or the Opera House, in the Haymarket, the largest of the kind in Europe, with the single exception of La Scala, at Milan. Built, in 1790, from the designs of Michael Novosielski, it was enlarged and altered by Nash and Repton in 1816. Covent Garden Theatre, or the Royal Italian Opera House, Bow Street, Covent Garden, is the third theatre erected on the same site. In 1847 the second of these was converted into an opera house, and in 1856 was destroyed by accidental fire. The present building (E. M. Barry, architect) was completed in the space of six months, at the cost of 80,000*l.*, and nearly equals the famous La Scala in point of size, as it can accommodate 2000 persons. Drury Lane Theatre (B. Wyatt, architect) is the oldest existing theatre in London, and it was opened in 1812 with a prologue written by Lord Byron. The portico in Brydges Street was added during Elliston's management (1819–26), and the colonnade in Little Russell Street a few years after. Within the vestibule is a marble statue of Edmund Kean as Hamlet. The Haymarket Theatre was erected by Nash, and publicly opened in 1821 (July 4). Among its managers, Foote, the Colmans, and Buckstone may be named. The Adelphi Theatre, opposite Adam Street, Strand, has lately been rebuilt by its lessee, Mr. B. Webster. The first house on its site was named the Sanspareil, and was built by one Scott, a colour-maker. The present theatre, 70 feet broad by 107 feet deep, possesses seats for 1400 persons. Astley's Amphitheatre, Westminster Bridge Road, Lambeth, and the City of London Theatre, Shoreditch, are chiefly used for melodramas. St. James', King Street, was built by Braham, the singer, at a cost of 26,000*l.*, and was opened in 1835; and the Lyceum, Wellington Street, Strand, was constructed from Beazley's designs in 1830, at the expenditure of 35,000*l.* The Marylebone, Church Street, Paddington, built in 1842, enlarged in 1854, will hold 2000 persons; the Olympic, Wych Street, Strand, was constructed in 1849; the Pavilion, Whitechapel Road, was erected in 1859, and will contain 3500 persons; the Prince of Wales, Tottenham Court Road; the Princess', Oxford Street, constructed in 1830 from Nelson's designs, cost 47,000*l.*; Sadler's Wells, Islington, built in 1764, is one of the oldest theatres in London; the Garrick, Whitechapel; the new Royalty, Soho; the Surrey, Blackfriars' Road; the Victoria, Waterloo Road; the Standard, Shoreditch, stands opposite the Great Eastern Railway station; and the Strand, opposite Wych Street, is a favourite little theatre.

The Clubs of London are luxurious social institutions, to which no other city can present a parallel. The principal are situated in Pall Mall and Waterloo Place, a region which has aptly been designated *Club-land*. The Athenæum is chiefly frequented by literary men; the Senior and Junior United Service, by naval and military officers. The Reform and the Carlton are the respective head-quarters of the two great political parties. Then we have the Travellers'; the Army and Navy; the Guards'; the Conservative; Arthur's; Brook's (the famous Whig Club); White's,

and Boodle's, now principally patronized by elderly country gentlemen; the Oriental; the Oxford and Cambridge, for members of the two universities; Naval and Military; the Civil Service; the Gresham; the Volunteers' Club; the Union; the University; the City and the New City Clubs, for merchants, bankers, and professional men; and the great literary club, known as the Garrick. The stranger may obtain admission to see some of these clubs by proper introductions to their members.

I. London Worthies.—The following illustrious personages were natives of the great metropolis:—Becket, archbishop of Canterbury; Sir Thomas More; Lord Bacon; the great earl of Stafford; the earl of Chatham; William Camden; John Stow, the historian; Geoffrey Chaucer, the father of English poetry; Edmund Spenser; John Milton; Ben Jonson; Abraham Cowley; Pope, the poet; Thomas Gray; Lord Byron; Inigo Jones, the architect; Hogarth; William Penn, the founder of Pennsylvania; Horace Walpole; and Charles James Fox. It would be easy to extend the list.

K. Public Buildings of Importance.—The British Museum, Great Russell Street, Bloomsbury, was first opened to the public in 1759, the trustees having purchased Montague House from Lord Halifax for the reception of certain valuable collections, among which were those of Sir Hans Sloane and the Cottonian and Harleian MSS. A full description of the building and the new reading-room will be found in the article *BRITISH MUSEUM*.

The South Kensington Museum at Brompton is situated about one mile distant from Hyde Park Corner, near the site of the International Exhibition of 1862. The ground was bought at a cost of 60,000*l.*; and a further outlay of 140,000*l.* has been made on the building and on those parts of the collections that have been purchased. The cost of management is about 7000*l.* a year.

The collections consist of—

1. Objects of ornamental art.
2. British pictures, sculpture, and engravings.
3. Architectural models, casts, &c.
4. School furniture, books, diagrams, models, and educational appliances.
5. Building materials, stone, bricks, tiles, glass, &c.
6. Nutritive substances.
7. Animal products employed in the arts, leather, furs, feathers, wools, &c.
8. Models of patented inventions, machines, &c.
9. Reproductions, by means of photography and casting, of antique sculpture and paintings.

Visitors are also shown a treasury of preserved articles from China, and collections of rhinoceros' hides and elephants' trunks, of china and pottery ware, glass, jewellery, fancy work in metals, mosaics, carvings in wood and ivories, &c., both antique and modern. With the exception of the Turner pictures, which are now in the National Gallery, Trafalgar Square, all the paintings of the English School belonging to the nation are exhibited at the South Kensington Museum, in galleries well lighted from above.

The collection of British pictures was commenced by Mr. Sheepshanks, and bequeathed by him to the Museum. The gift has been valued at 52,895*l.*; and was followed by a gift of water-colour paintings by Mrs. Ellison, valued at 8000*l.*

The National Gallery occupies the northern side of Trafalgar Square, and stands on the site of the King's Mews. It is divided between the national collection of paintings of the old masters, filling the western half; and the Royal Academy, occupying the eastern half. Originally founded in 1824, the present building was erected in 1832–38, from the designs of W. Wilkins, R.A., at the cost of 96,000*l.* The columns of the portico were those of Carlton House.

The gallery originated in the purchase by government, in 1824, of Mr. Angerstein's collection of thirty-eight pictures for 57,000*l.* In 1826 it received a donation from Sir George Beaumont of sixteen pictures, valued at the time at 7500 guineas; and bequests by the Rev. W. H. Carr, Lord Farnborough, and others, have brought the collection, in less than half a century, to nearly 250 pictures, independently of Mr. Vernon's munificent gift of 162 English paintings.

In the Italian School, we find paintings by the great masters, Raffaele, Da Vinci, Perugino, Correggio, Titian, Caracci, Guido, Claude, Salvator Rosa, and Paul Veronese; in the Spanish School, pictures by Velasquez and Murillo; in the Flemish School, paintings by Van Eyck, Rubens, Van Dyck, Rembrandt, Cuyp, and Teniers; in the French School, by Bourdon and the two Poussins; and in the English School, by J. M. W. Turner, R.A., bequeathed to the English nation, on condition that they should hang as companions to the Claudes in the National Gallery. Considerable alterations are at present contemplated in the building, which will much improve its architectural character, and provide additional accommodation for its rapidly increasing collections.

St. Paul's Cathedral is the most prominent object in the metropolis. Its lofty dome, seen for miles around, stands at the head of Ludgate Hill, where a church is said to have existed four hundred years before the Conquest, but it was burnt down in 1666, during the great fire of London. An entirely new edifice was then erected under the auspices of Sir Christopher Wren, and was first opened for divine worship in 1697.

The cathedral is built in the form of a cross, 514 feet in length, by 286 in breadth. Outwardly, the walls exhibit a double range of windows; there are three porticoes at as many entrances on the north, west, and south, of which that on the west is the principal, facing towards Fleet Street, with twelve lofty Corinthian pillars below, and a second order carrying the pediment above. The angles are crowned with handsome bell-towers, the size of ordinary church steeples, and 222 feet high. It is strange that, in relation to the best known building in London, great discordance exists concerning the total height. Wren's son, in the *Parentalia*, simply states that the lantern is 330 feet from the ground; Maitland gives the total height at 340 feet; many authorities name 360 feet; while several hand-books and guides, following the pamphlet sold in the cathedral, raise it to 404 feet. This last statement agrees with the well-known tradition that St. Paul's is twice as high as the Monument. A careful examination of the vertical section, however, shows that the height is about 356 feet above the marble pavement of the cathedral, 375 above the level of the crypt, and 370 above the pavement of the churchyard. It

will thus be sufficiently near the truth to say that St. Paul's is 365 feet high.

There are two domes, an outer and an inner, having a brick cone between them. The inner dome has six paintings, relating to the life of St. Paul, and painted by Sir James Thornhill. The organ has been placed on the north side of the choir, and the screen on which it lately stood has been removed, thus throwing open the beautiful choir to view from the nave.

The various parts of the building comprise—the whispering gallery, which renders every whisper audible from side to side; the library, containing chiefly ecclesiastical works for the use of the chapter; and the two golden galleries, at the top of the inner and outer domes. The ball and cross, reached by more than 600 steps, are at the summit of the building; the ball, about 6 feet in diameter, being reached with great difficulty. The clock-work and great bell excite much attention from visitors. The pendulum measures 14 feet in length, while the mass at its extremity is one hundredweight. The great bell, which is only tolled when a member of the royal family dies, is placed in the southern turret above the western portico, weighs $4\frac{1}{2}$ tons, and is 10 feet in diameter.

During the administration of the present dean (the Rev. Dr. Milman) much has been done to improve and embellish the interior of the cathedral, and to complete it according to the magnificent design of its great architect.

Westminster Abbey is situate opposite the Houses of Parliament. In early times its site was a small insular tract, surrounded by the waters of the Thames, and called Thorney Island. Here a monastic institution was founded, which became a ruin during the reign of the Confessor, who raised an abbey among the shattered remains. The ground-plan, as usual, bore the form of a cross. Various privileges and endowments were granted to it, and the edifice assumed a great degree of architectural grandeur. It soon became a place for the coronation of our monarchs, and William the Conqueror was crowned here in 1066. The Abbey was enlarged by Henry III. and Edward I., and continued nearly in the state they left it, until Henry VII. added a chapel to the original structure, in the Perpendicular style, upon which the highest skill of the architect and sculptor was lavished. It was universally regarded as one of the most splendid edifices of the age, and was specially reserved as the place of sepulture of our English sovereigns.

During the reign of Henry VIII. the abbey was considerably defaced; but on the surrender of its revenues, the king raised Westminster to the dignity of a city, and its abbey was constituted a cathedral. In 1855, however, it was united to the see of London. In the reign of William and Mary it was thoroughly repaired, and the towers added to the western entrance, under the direction of Sir Christopher Wren. The present length of the abbey is 416 feet; breadth of the transept, 203 feet; at the nave, 102 feet; height of the west towers, 225 feet. The exterior measurement, including Henry VIII.'s chapel, is 530 feet.

The interior is of great magnificence, and displays grand masses of marble columns separating the nave from the side aisles. A screen, on which the organ

rests, divides the nave from the choir; whilst the walls are covered with a profusion of sepulchral monuments. The northern window is richly ornamented with stained glass. At the eastern end of the choir stands the chapel of Edward the Confessor, containing the shrine of St. Edward. Here also is the coronation chair of the Scottish kings, brought from Scone by Edward I. in 1297; and the chapel of Henry VII., in which lie the ashes of Queens Mary and Elizabeth. The magnificent tomb of Henry VII. and his queen is placed in the body of this chapel, in a curious chantry of cast brass, admirably executed, and interspersed with effigies, armorial bearings, and devices relating to the union of the Red and White Roses.

Statues are numerous in the abbey, and are chiefly contained in side chapels, of which there are several: viz., St. Benedict's, St. Edmund's, St. Nicholas', St. Paul's, St. Erasmus', John the Baptist's, and Bishop Islip's, besides those of Henry VII. and Edward the Confessor. The choir, transept, and nave also contain many specimens of sculpture, from the chisels of Flaxman, Chantrey, Roubiliac, Bacon, Westmacott, Gibson, Behnes, and others. Poet's Corner is the famous receptacle of the busts of English worthies. The last person of eminence buried in the abbey was the venerable Viscount Palmerston, so justly esteemed as an English statesman. The cloisters and the chapter house contain some curious old effigies. Westminster Abbey is a collegiate church, with a dean and chapter, who possess considerable authority over the adjoining district, and a revenue of about 30,000*l.* per annum.

The Temple Church belongs to the two Temples—the Inner and Middle. The members of the former occupy the southern half, and those of the latter the northern. The entrance doorway is of great interest. The Round Church, 58 feet in diameter, affords one of the early examples of pointed arches in this island. The clerestory is pierced by six Romanesque windows, whilst the vaulting is supported by six clustered pillars of Purbeck marble, with boldly sculptured capitals. The Rectangular Church, or Choir, is in the Early English style. It is 82 feet by 58 feet, with a height of 60 feet, the roof being painted with Arabesques, and triple lancet-headed windows admitting light. The great east window is ornamented with modern stained glass; and on the wall, beneath the windows, the hymn of St. Ambrose is inscribed. The organ was built by one Schmydt, after a competition with another builder, which Judge Jeffreys was called upon to decide. The most notable of the monuments scattered about the church are those of Plowden, the jurist; Anne Lyttleton; Howell, the old letter-writer, and an ancestor of Gibbon, the historian. In the Triforium may be seen a bust of Lord Chancellor Thurlow. The walls are inscribed with texts from the Latin scriptures. In 1839–42 70,000*l.* were laid out in restorations. The preacher at this church is designated the Master of the Temple; his house is north-east of the choir, and has a small garden attached to it.

Westminster Palace, which occupies a site close to the river and to the beautiful new Westminster Bridge, was constructed in consequence of the burning of the old Houses of Parliament in 1834. It is

the finest modern Gothic structure in the world—at least for civil purposes—and covers an area of nearly eight acres. Among the multitudinous objects of interest in this gorgeous building, which has cost more than two millions sterling, the following may briefly be mentioned:—The House of Peers is 97 feet long, 45 wide, and 45 high. It is profusely gilt and painted, and the windows are ornamented with deep-tinted stained glass. At the southern end is the splendidly canopied throne; near the centre is the woolsack; at the end and sides are galleries for the peeresses, reporters, and strangers; and on the floor of the house are the cushioned benches for the peers. Six frescoes, representing 'The Baptism of Ethelbert,' by Dyce; 'Edward III. conferring the Order of the Garter on the Black Prince,' by Cope; 'Henry, prince of Wales, committed to prison for assaulting Judge Gascoigne,' by Cope; 'The Spirit of Religion,' by Horsley; and the 'Spirit of Chivalry' and 'The Spirit of Justice,' by Maclise—occupy compartments at the ends of the chamber, and in niches between the windows stand eighteen statues of barons who signed Magna Charta. The House of Commons, 62 feet long, 45 broad, and 45 high, is less elaborate than the House of Peers. The Speaker's chair is at the north end, and there are galleries along the sides and ends. In a gallery behind the speaker sit the reporters for the newspapers.

The two chambers mentioned do not constitute the whole palace. On the side nearest Westminster Abbey are St. Stephen's Porch and Corridor, the Chancellor's Corridor, the Victoria Tower, Royal Staircase, and numerous courts. At the south end are the Guard Room, Queen's Robing Room, Royal Gallery, Royal Court, and Prince's Chamber. Libraries and committee-rooms line the river. On the north are the Clock Tower and Speaker's residence. The Victoria Tower, at the south-west angle of the palace, is one of the finest in the world, and is 75 feet square and 340 feet high. The Clock Tower is 40 feet square and 320 feet high, and has four fine bells, varying from $1\frac{1}{2}$ and $4\frac{1}{2}$ tons in weight, to strike the quarters. The clock is the largest in this country. There are four dials on the four faces of the tower, each $22\frac{1}{2}$ feet in diameter; the hour figures are 2 feet high and 6 feet apart; the minute-marks are 14 inches apart; the hands weigh more than 2 cwt. the pair; the minute-hand is 16 feet long, and the hour-hand 9 feet; the pendulum is 15 feet long, and weighs 680 lbs.; the weights hang down a shaft 160 feet deep. Besides, there is a Central Tower, rising over the octagonal hall to the height of 300 feet.

St. James' Palace is an inelegant brick structure, fronting Pall Mall. It occupies the site of a leper's hospital, dedicated to the saint. It is asserted that Holbein designed the house; which has been much favoured by royalty. Here Mary resided and died; here Charles II., the 'Old Pretender,' and George IV. were born. Queen Anne, the Georges, and William IV. have also made the palace their residence; and here the emperor of Russia, king of Prussia, and Marshal Blucher lodged in 1814. It is still used by the sovereign on state occasions, such as courts, levees, and drawing-rooms.

Westward lies the Ambassador's Court, and beyond it the Stable Yard, where stands Stafford House, the

splendid residence of the duke of Sutherland. The state rooms are in the south front, looking across the gardens into the park, and contain a few pictures, chiefly portraits.

On the site of Buckingham Palace originally stood the mansion, built in 1703, of Sheffield, duke of Buckingham. George III. purchased it in 1761 for 21,000*l*. It retained its original condition until 1825, when Nash undertook its reconstruction. In 1837 Queen Victoria took possession of the palace, and she has continued to reside there when in London ever since. Extensive alterations have been made to render it more suitable for her Majesty, and a new front erected from the designs of Mr. Blore. The private apartments extend along this front.

The east wing is 360 feet long and 77 feet high, and 70 feet in advance of the other wings, and it cost 150,000*l*. The state ball-room is 111 feet long by 60 wide, and here are hung Vandyck's Charles I. and his Queen, and portraits of Queen Victoria and the late Prince Consort, by Winterhalter; the adjoining Supper-room is 76 feet by 60. The Library contains a valuable collection of books made by the present sovereign; the Green Drawing Room, in the middle of the east front, opens upon the upper portico; the Throne Room, 64 feet long, is gorgeously decorated with crimson satin and gilding; and the Picture Gallery, 180 feet long by 26 wide, runs along the centre from north to south, opening at each side into suites of apartments.

In the gardens, 40 acres in extent, stands a pavilion, embellished with many paintings; and the chapel, where the Court attends divine service.

The Tower of London is a cluster of houses, towers, barracks, armouries, warehouses, and prison-like edifices, situated on the north bank of the Thames. The date of its erection is undecided; but it is well known that the great square tower in the centre, called the White Tower, was built by William the Conqueror. Such is the origin of the fortress: by successive monarchs it was greatly extended, and in the twelfth century received the addition of a moat, which was much improved by Charles II., and finally drained in 1843.

Of the various divisions of the Tower, the Horse Armoury is contained in a gallery 150 feet long by 33 feet wide, built in 1826 on the south side of the White Tower. The general arrangement of the gallery was confided to Sir Samuel Meyrick. The centre is occupied by a line of equestrian figures, 22 in number, and clothed in the armour of various reigns, from the thirteenth to the seventeenth century. Queen Elizabeth's Armoury, entered by a narrow staircase, is situated in the White Tower, and has walls 14 feet in thickness. The Jewel House within the Tower was kept by a particular officer called the 'Master of the Jewel House,' formerly esteemed the first knight bachelor of England. The Regalia are arranged in a glazed iron case in the centre of a well-lighted room. The Lion Tower, containing the Tower Menagerie, was one of the sights of London from the reign of Henry III. to that of William IV., when the few animals remaining were removed to the Zoological Gardens in Regent's Park.

Amongst the eminent persons at different times confined in the Tower, we can but enumerate—

Wallace; John, king of France; Queens Anne Boleyn and Catherine Howard; Sir Thomas More; Archbishop Cranmer; the Protector, duke of Somerset; Lady Jane Grey; Sir Walter Raleigh (thrice a prisoner); Lady Arabella Stuart; Sir John Eliot; Sir William Davenant, the poet; Sir Harry Vane; Lord William Russell; Algernon Sidney; Judge Jeffreys; the duke of Marlborough, 1692; Sir Robert Walpole; Bishop Atterbury, 1722; Lord George Gordon; Sir Francis Burdett, 1810; and Arthur Thistlewood, 1820, the last person sent prisoner to the fortress. Amongst the persons executed or murdered therein are—Henry VI.; duke of Clarence, brother of Edward IV.; Edward V. and the duke of York; Sir Thomas Overbury; and Arthur Capel, earl of Essex. Whilst the following were born there:—Carew Raleigh, son of Sir Walter; Mrs. Colonel Hutchinson; and the countess of Bedford, mother of Lord William Russell. Of the celebrated persons executed on Tower Hill we may name, Sir Thomas More; Cromwell, earl of Essex; the earl of Surrey, 1541; the Protector Somerset, 1552; Dudley, earl of Warwick, 1553; earl of Strafford, 1641; Archbishop Laud; Algernon Sidney; and the duke of Monmouth, as the most eminent.

The Bank of England covers a quadrangular space of four acres, with a street on every side; and its buildings are of one story, having no windows towards any of the thoroughfares. The external architecture is not such as to attract much attention, if we except the north-west corner, which was copied from the temple of the Sibyl at Tivoli. The interior, which is well arranged for business, contains nine courts in addition to the offices.

This powerful establishment, which occupies so conspicuous a position in commercial and financial affairs, was planned by a Scotchman named Pater-son, in 1691, and received its charter under the designation of 'The Governor and Company of the Bank of England,' from William III., in 1694. The capital of 1,200,000*l.* was lent to the government. The company in 1734 removed to the site of the present establishment, having previously carried on business at Grocers Hall. The history of the Bank includes many dangerous crises, amongst which are the rebellion of 1745, when its payments were made in sixpences to save time; the war with France, at the end of last century, when cash payments were suspended by Parliament and not resumed until 1823; and the commercial difficulties in 1825, when its treasure was reduced to a very low ebb. The Bank has met with some heavy losses from forgeries; by Astlett it lost 320,000*l.*, and by Fauntleroy, 360,000*l.*

The affairs of the Bank are regulated by a governor, deputy-governor, and twenty-four directors, eight of whom go out of office every year. The proprietors of stock to the value of 500*l.* are qualified to vote for the election of directors. The governor must be a proprietor to the amount of 4000*l.*, the deputy-governor to that of 3000*l.*, and a director to that of 2000*l.* The number of persons employed in the Bank are about 900. The salary of a clerk entering at seventeen is 50*l.*, and that of the head of a department 1200*l.* Altogether, the sums paid in salaries amount to 210,000*l.* annually. The profits of the Bank arise from different sources: notes are issued,

deposits received, bills discounted, loans made, &c. Besides, the remuneration derived from the management of the national debt, book-keeping, attendance to the transfers, receipt of the taxes, payment of discount, &c., amounts to about 200,000*l.* a year. [BANK OF ENGLAND.]

The Royal Exchange, a quadrangular edifice on the west side facing down Cheapside, was erected for the convenience of merchants and bankers, after the designs of William Tite, and was opened by Queen Victoria, October 28, 1844. The sculpture in the pediment was by R. Westmacott, jun. The Exchange consists of an open court surrounded by a colonnade, with a marble statue of her Majesty, by Lough, opposite the façade. It is said to have cost 180,000*l.*, but is now much disfigured externally by shops, in opposition to the firmly expressed wishes of its architect.

In the east part, up stairs, are Lloyd's Subscription Rooms, which are entered by the area, near the eastern gate. On the architrave of the north façade of the Exchange are three inscriptions in relief, each divided by a simple moulding. The one on the left of the spectator is the City motto, '*Domine, dirige nos,*' and that on the right, '*Honor Deo.*' That of the central department is '*Forton a my,*' the motto of Sir Thomas Gresham, the founder of the first Royal Exchange, 1566, which was opened by Queen Elizabeth, 1570.

The Custom House, situated in Lower Thames Street, between London Bridge and the Tower, and facing the river, occupies a site on which smaller custom houses have formerly stood. It was erected in 1814–17, after the designs of Mr. David Laing; but in consequence of a defect in the piling the original structure was pulled down, and the present front erected by Sir Richard Smirke. Nearly one-half of the customs receipts of the United Kingdom is collected here.

The most noticeable feature of the building is the Long Room, 190 feet long by 66 feet broad. The quay is a pleasant terrace fronting the Thames, whence a fine view of the shipping is obtained.

A custom house was erected in 1804; a yet larger one in 1559, which was burned down in 1666; a new one, built by Charles II., burned down in 1718, rebuilt in 1718, was again destroyed February 12, 1814; the present edifice was opened for business May 12, 1817.

The General Post-Office, near St. Paul's, Cheap-side, and Newgate Street, stands on the site of the Collegiate Church of St. Martin's-le-Grand, and was built 1825–29, from designs of Sir R. Smirke.

The building is a good specimen of the Ionic style, with a lofty portico, beneath which is the entrance to the spacious hall, 80 feet long, 60 feet wide, and 53 feet high. A money order office has been built on the opposite side of the street, and increased accommodation has been added to the Post-Office for the easier transaction of its rapidly-increasing business. At the north end is a courtyard, in which the various mail carts congregate. At other portions of the building the foreign, colonial, and Indian mails are despatched.

The palatial building in the Strand, known as Somerset House, was erected in 1549 by the duke of Somerset, Protector during a part of the minority of

Edward VI. On his attainder it became crown property and a royal residence. That edifice was entirely removed in the reign of George III.; and on the spot was erected, from designs of Sir William Chambers, about the year 1780, the fine quadrangular structure which is now devoted to the accommodation of various government offices. This building has its main front towards the Strand; while on the rear it presents a façade to the Thames, which it closely overhangs. The river frontage is 600 feet long, and is an excellent specimen of Palladian architecture. The ranges of buildings contain rooms for two or three learned societies, and offices for several government departments—especially those of such portions of the Admiralty as cannot be accommodated at Whitehall, the Inland Revenue, and the Registrar-general. Nearly a thousand clerks are employed in these various offices. Most of the other government offices sink into insignificance when compared with the three structures just described. The Admiralty, in Whitehall, is the head-quarters of the Naval Department; the front of the building was constructed about 1726; and the screen by the brothers Adam about half a century later. Most of the heads of the Admiralty have official residences connected with the building. The Horse Guards, a little further down Whitehall, is the head-quarters of the commander-in-chief. It was built about 1753, and has an arched entrance leading into St. James' Park. The Treasury, the Home Office, the Privy Council Office, and the Board of Trade, together occupy the handsome range of buildings at the corner of Whitehall and Downing Street. The interior of this building is in great part old; after many alterations and additions, the present front, in the Italian Palazzo style, was built by Sir Charles Barry in 1847. The Foreign Office, Colonial Office, and Exchequer Office, occupy gloomy and dilapidated houses in Downing Street, or near at hand. After many years of debate and difficulty, large, elegant, and costly Foreign and India Offices are being constructed southward of Downing Street.

The War Office comprises several houses thrown into one, in Pall Mall; it is a large but heterogeneous building, one among many makeshifts of the kind. An immense rental is paid by the government for the hire of private houses in various parts of Westminster, for the accommodation of numerous departments not provided for elsewhere; it is believed that this rental, if capitalized, would defray the cost of a new, extensive, and comprehensive series of government offices. The 'Battle of the Styles,' as it has been called, concerning new offices about to be built, was fought for many years between governments, commissions, and committees; it ended in a compromise; the Gothic architect (Mr. G. G. Scott, R.A.) is employed, but an Italian design is being adopted for the new Foreign and India Offices. A noble Gothic building, known as the National Record Office, now in course of completion in Fetter Lane, is destined to receive all the public documents and MSS. relating to this country of ancient and modern times.

The Metropolitan Docks are the finest and most extensive in the world. Farthest down the river are the Dagenham Docks, situated between Barking and Tilbury, on the Essex side of the Thames, now in course of completion, and destined for the accommodation of all classes of vessels entering the port of

London. The average width is 600 feet, and the length about one mile, thus affording nearly two miles of quay. The tidal basin is 450 feet long and 250 feet wide, the entrance gates 70 feet in width, with 27 feet of water on the sill at ordinary high tide, and the minimum depth 12 feet at low water. The cost of construction of the docks, including the freehold of Dagenham Lake and the adjoining lands, altogether about 140 acres, was 220,000*l.* Below Blackwall, just beyond the Lea, are the Victoria (London) Docks. These were completed in 1855, cover an area of 200 acres, and have been the means of introducing many improvements in the accommodation of shipping. The hydraulic lift for raising and supporting ships whilst under repair attracts much attention. Next are the East India Docks, commenced in 1803, and finished in 1806. These consist of two docks and a basin, and were originally constructed for the East India Company. The import dock has an area of 19 acres, the export dock of 10 acres, and the basin of 3—making a total surface of 32 acres. The cast-iron wharf, 750 feet long, is said to weigh 900 tons. The West India Docks, the most magnificent in the world, cover 295 acres, and lie between Limehouse and Blackwall, on the left bank of the Thames. The first stone was laid by the Great Commoner, William Pitt, in 1800, and the docks opened for business two years later. The import division is 170 yards long by 166 wide, and will contain 250 vessels, having an average measurement of 300 tons each. The export dock is a canal about three-quarters of a mile long, and connects Limehouse and Blackwall Reaches. Near the Tower are St. Katherine's Docks, of which the first stone was laid in 1827. They were publicly opened in 1828, 1250 houses, including the old hospital of St. Katherine, having been purchased and pulled down. The architect was Mr. Hardwick, and the celebrated John Telford the engineer of the structure, of which Sir John Hall, the late secretary, was the chief promoter. The total cost was 1,700,000*l.* The area of the docks is about 24 acres, of which 11½ are in water; and the lock is sunk so deep that ships of 700 tons burthen may enter at any time of the tide. Of the London Docks the first and largest (John Rennie, engineer) was opened in 1805, having occupied three years in construction. The New Tea Warehouses, capacious enough to receive 120,000 chests, were erected in 1844–45, and comprise an area of 90 acres. There are 20 warehouses, 18 sheds, 17 vaults, and 6 quays, with three entrances from the Thames. The entire structure cost 4,000,000*l.*, which is the capital of the shareholders. The Commercial Docks consist of five ample and commodious docks on the south side of the river, with an entrance from the Thames. They were opened in 1807, and comprise 49 acres, 40 of which are in water, principally used by vessels engaged in the Baltic trade. The grain stores will hold about 100,000 quarters. The removal of mud, deposited in the docks by the steam navigation of the Thames, costs the company on an average about 1000*l.* a year.

L. Literary and Educational Resources.—The museums and libraries in London open to the public, or easily accessible, are the following:—The British Museum, already described. South Kensington Museum, and Museum of Patent Inventions. Crystal Palace, Sydenham. There are museums and

special collections attached to University and King's Colleges; and (among others) to the Antiquarian Society, Somerset House; City Museum, Guildhall; Royal Institution, Albemarle Street; India Office, Whitehall Yard; Royal Asiatic Society, New Burlington Street; Soane Museum, Lincoln's Inn Fields; Naval Museum, Somerset House; Society of Arts, Adelphi; Trinity House, Tower Hill; Linnean Society, Piccadilly; Royal Botanic Society, Regent's Park; Practical Geology, Jermyn Street; Architectural Museum, South Kensington; War Office, Pall Mall; Royal United Service, Whitehall Yard; London Missionary House, Bloomfield Street, City; Zoological Society, Hanover Square; Entomological Society, Bedford Row; Royal College of Surgeons, Guy's Hospital, Borough; St. Bartholomew's, King's College, and other hospitals, and the Veterinary College, Camden Town, for anatomical preparations; Bank of England; Artillery Company, Armourer's Hall, the Tower, and Woolwich Repository and Arsenal, for arms and armour.

The two chief colleges in London are connected with the London University. This university is a body of persons, not (as many suppose) a building. The body was established in 1837, to confer degrees on the students or graduates of many different colleges in and about London. It occupies apartments at Burlington House, Piccadilly, lent by the government; but it neither teaches nor gives lectures. [UNIVERSITY OF LONDON.] University College, in Gower Street, was originally called London University; but since 1837 the more limited designation has been given to it. It was founded in 1828, on the proprietary system; to afford a good middle-class education at a moderate expense, without limitation as to religious tests. The whole range of university tuition is given, except divinity; with the addition of much fuller instruction in science and in modern languages than was before usual in colleges. The building, with its lofty portico, might possibly have presented a good appearance if the plans of the architect had been carried out; but through want of funds the wings have never been built, and the structure is ridiculously incomplete. King's College, in the Strand, adjoins Somerset House on the east. It was founded in the same year as University College, expressly in connection with the Established Church of England. Gordon College, or University Hall, in Gordon Square, is an establishment mainly supported by Unitarians. New College, at St. John's Wood, for Congregationalists or Independents; the Baptist College, in the Regent's Park; the Wesleyan College, in the Horseferry Road; Hackney College; and several others of less importance—are establishments maintained by various bodies of dissenters; some for educating ministers for the pulpit; some for training schoolmasters and schoolmistresses. Of the buildings so occupied, the handsomest is New College. This was established a few years ago as a substitute for Highbury, Homerton, and Coward Colleges, all belonging to the Congregationalists. Gresham College: this is not a college in the modern sense of the term; it is only a lecture-room. Sir Thomas Gresham left an endowment for an annual series of lectures, and residences and stipends for the lecturers. The charity was greatly misused during the seventeenth and eight-

eenth centuries. Public attention having been called to the subject, a new lecture hall was built a few years ago, at the corner of Basinghall and Gresham Streets, out of the accumulated fund; and lectures are delivered here at certain periods of each year. The subjects are divinity, physic, astronomy, geometry, law, rhetoric, and music. The lectures take place in the middle of the day, some in Latin, some in English; they are freely open to the public; but the auditors, at such an hour and in such a place—surrounded by the busy hum of commerce—are very few in number. Among the training colleges for school masters and mistresses are the National Society's at Chelsea, the British and Foreign in the Borough Road, and the Home and Colonial in Gray's Inn Road. The College of Preceptors, in Queen Square, resembles the London University in this—that it confers a sort of degree or academical rank, but does not teach. Many so-called colleges are either proprietary or private schools.

The chief of the public schools in London is Westminster School. It was founded in 1560, and lies south-west of Westminster Abbey, but very near it. Some of our greatest statesmen and scholars have been educated here. St. Paul's School, situated on the eastern side of St. Paul's Churchyard, was founded in 1512 by Dean Colet, for the education of 'poor men's children.' Like many others of the older schools, the benefits are not conferred so fully as they ought to be on the class designated. The presentations are wholly in the hands of the Mercers' Company. The now existing school-house, the third on the same site, was built in 1823. The Charter House School, near Aldersgate Street, is part of a charity established by Thomas Sutton in 1611. There is an hospital or almshouse for about eighty 'poor brethren,' men who have seen better days; and there is a school for the free education of forty 'poor boys,' with many more whose parents pay for their schooling. Christ's Hospital, or the Blue Coat School, as it is commonly called from the colour of the boys' dress, is situated within an inclosure on the north side of Newgate Street, and is one of the most splendid among the charitable foundations of London. The buildings stand on the site of a monastery of Greyfriars, which was granted by Henry VIII. to the city for the use of the poor; and his son and successor, Edward VI., greatly extended the value of the gift by granting a charter for its foundation as a charity school, and at the same time endowing it with sundry benefactions. The hospital was opened for the reception and education of boys in 1552. Charles II. added an endowment for a mathematical class; and with various augmentations of endowment, the annual revenue is now understood to be not less than 50,000*l*. This income supports and educates nearly 1200 children, 500 of the youngest of whom, and all the girls, are boarded at the town of Hertford for the sake of country air. The management of the institution is vested in a body of governors, composed of the lord mayor and aldermen, twelve common-councilmen chosen by lot, and all benefactors to the amount of 400*l*. and upwards. The children are admitted without reference to the City privileges of parents; about 150 are entered annually. It is undeniable, however, that many children are admitted rather through interest than

on account of the poverty of their parents. After instruction in the elementary branches of schooling, the greater number of the boys leave the hospital at the age of fifteen: those only remaining longer who intend to proceed to the university, or to go to sea after completing a course of mathematics. There are seven presentations at Cambridge, and one at Oxford, open to the scholars. The buildings of the institution embrace several structures of large dimensions, chiefly ranged round open courts, with cloisters beneath; and a church, which also serves as a parochial place of worship. The boys are dressed in the costume selected for them in Edward VI.'s reign; the outer garments consisting of a long dark-blue coat, breeches, and yellow worsted stockings. Merchant Taylor's School, situated in a close part of the city behind the Mansion House, was founded in 1561 by the Merchant Taylors' Company. The present structure was built in 1673, with the exception of some of the class-rooms, which are much more modern. About 260 boys are educated, wholly on the presentation of members of the Company; and there are numerous fellowships at St. John's College, Oxford, open to the scholars. Mercers' Free Grammar School, in College Hill, is a small establishment of similar kind. The City of London School, in Milk Street, Cheapside, is the most modern of these Grammar-schools, as they are called. It was founded in 1835, and forms a useful medium between the old grammar-schools and the modern private schools; it possesses several exhibitions for the more successful senior scholars.

The schools established under the auspices of the National Society, called National Schools, are very numerous, but need not be noticed here. The British and Foreign School Society, in the Borough Road, and the Home and Colonial School Society, in Gray's Inn Road, train up teachers without reference to religious tests; whereas the National Society is in connection with the Church of England. Many very superior schools for girls, under the designation of Ladies' Colleges, have been established in the metropolis within the last few years. Few of the school-houses in London are worth much attention, so far as concerns their architectural features.

Altogether the metropolis may be said to be well provided with the means of educating its children; and of late years a noble effort has been made, by Lord Shaftesbury and others, in the establishment of ragged schools, to extend these advantages to the 'London Arabs,' the lowest and most destitute, the very 'pariahs' of society. The experiment has been attended with so much success as to justify its development on a larger scale.

M. Charitable Institutions.—In no respect is the metropolis more worthily distinguished than in the number and splendour of its charitable institutions, which minister to every want of humanity, and whose aggregate income exceeds the revenue of several important European states. They include hospitals, almshouses, and schools. Among the former are especially noticeable the Chelsea Hospital, for old and disabled soldiers, founded in the reign of Charles II.—the buildings which face the river Thames were the work of Sir Christopher Wren; the Royal Military Asylum, to the north of the hospital, where the children of soldiers are supported and educated; the

Foundling Hospital, Guildford Street, founded in 1739 by Thomas Coram, for the maintenance of illegitimate children; St. Bartholomew's Hospital, Smithfield, founded by Henry VIII., now containing 650 beds, with an income of about 35,000*l.* yearly; St. Thomas' Hospital, opened in 1552, and about to be rebuilt; Guy's Hospital, Southwark, so named from its founder, built in 1722–24, possessing a yearly income of 25,000*l.*; University College Hospital, founded in 1833; Westminster Hospital; Charing Cross Hospital, founded in 1818; St. George's, Great Northern, King's College, the London, St. Mary's, Middlesex, Royal Free; the Dreadnought, for sick and diseased seamen of all nations, who are attended to on board the *Caledonia*, a man-of-war moored in the Thames near Greenwich; Bethlehem and St. Luke's, for the reception of lunatics; the Cancer, Consumption, and Fever hospitals, and numerous other institutions for the treatment of special diseases. These are supported by endowments, legacies, and yearly contributions from the benevolent; their annual income being supposed to be not less than 2,000,000*l.* The local and parochial charities are organized on an equally splendid scale; and their annual revenues—devoted chiefly to the education and apprenticeship of children, endowment and repair of churches, and support of almshouses—cannot be less than 200,000*l.*

Among the charities of London may properly be included its Drinking Fountains, now amounting in number to about 150, where the thirsty thousands of the metropolis may obtain water, day and night, 'without money and without price.' Several of these have been erected at the cost of private individuals, but the majority under the auspices of the Metropolitan Free Drinking Association, and all within a period of six years.

Night refuges have also been established for the poor and needy, where a supper, a bed, and a breakfast are gratuitously supplied; and in winter numerous soup kitchens supply the hungry with a bountiful and nutritious meal. There are about seventy almshouses, and 200 infirmaries, dispensaries, and asylums.

N. Police and Prisons.—An official statement recently published shows the number of men at present employed in the City police, together with the estimated expense for the year 1866, and other particulars. It appears by this return that the City police force consists of 635 men, thus divided:—One superintendent, at 4*l.* 18*s.* 6*d.* per week salary; 2 inspectors, at 3*l.* 6*s.* 7*d.*; 4 ditto, at 3*l.* 1*s.* 6*d.*; 4 ditto, at 2*l.* 16*s.* 4*d.*; 4 ditto, at 2*l.* 11*s.* 3*d.*; 14 station sergeants, at 2*l.* 1*s.*; 12 detective sergeants, at 2*l.* 1*s.*; 25 sergeants, at 1*l.* 14*s.* 10*d.*; 25 ditto, at 1*l.* 11*s.* 9*d.*; 271 constables, at 1*l.* 8*s.* 8*d.*; 150 ditto, at 1*l.* 5*s.* 1*d.*; 123 ditto, at 1*l.* 1*s.* 6*d.*; total, 635 men, at a cost of 47,048*l.* 19*s.*, which includes some extra allowances to some of the detective officers. The salary of the commissioner is 1000*l.* per annum; that of the chief superintendent, 600*l.*; that of the surgeon, 500*l.*; the receiver's salary is 350*l.*; and the clerks' salaries are 467*l.*,—namely, one at 180*l.*, one at 135*l.*, one at 100*l.*, and one at 52*l.* The total amount of expense incurred for the maintenance of the body, including rent of stations, office expenses, and all other items, in 1865 was

63,219*l.* 10*s.* 6*d.*, equal to about 10*d.* in the *l.* on the rateable value of the City property.

The chief office is situated in the Old Jewry, and there are six minor stations, connected with each other, and the central station, by electric telegraph. The Justice Rooms are at the Mansion House and Guildhall.

The Metropolitan Police, established in 1829, are placed under a chief commissioner, responsible to the home secretary of state, at the head office in Great Scotland Yard, Whitehall. The divisions are—

A Whitehall.	M Southwark.
B Westminster.	N Islington.
C St. James'.	P Camberwell.
D St. Marylebone.	R Greenwich.
E Holborn.	S Hampstead.
F Covent Garden.	T Kennington.
G Finsbury.	V Wandsworth.
H Whitechapel.	T.D. Thames Police Division.
K Stepney.	
L Lambeth.	

The body, as at present constituted, includes 21 superintendents, 217 inspectors, 798 sergeants, and 6452 constables. The superintendents receive salaries varying from 150*l.* to 325*l.* per annum; the inspectors from 81*l.* 18*s.* to 199*l.* 19*s.* 8*d.*; the sergeants from 63*l.* 14*s.* to 109*l.* 4*s.*; and the constables from 49*l.* 8*s.* to 78*l.* The total yearly expenditure amounts to 630,604*l.* 15*s.* 9*d.* This is defrayed in part by a grant from the Treasury, amounting to 156,481*l.* 1*s.* 5*d.*, and in part by a police rate levied from the various metropolitan parishes, which yielded (1865-66) 389,873*l.* 13*s.* 3*d.*

The London Prisons are as follows:—Bridewell Royal Hospital, New Bridge Street; Newgate Prison, Old Bailey, rebuilt 1782, the common gaol for Middlesex, for prisoners within the Metropolitan Police District. House of Correction, for Middlesex, Cold-bath Fields, for males only; Middlesex House of Detention, Clerkenwell, for untried prisoners; Millbank Penitentiary, general, for males and females; City Prison, or House of Correction at Holloway; for criminals apprehended in the City only; Fulham and Brixton, for female convicts; Model Prison, Pentonville, for male convicts, on the separate system; House of Correction for Middlesex, Tothill Fields, Westminster, for females only; Surrey Gaol; Horse-monger Lane, for criminals and debtors; Surrey House of Correction, Wandsworth; Debtor's Prison, Whitecross Street.

O. Public Works and General Statistics.—The management of the sewers, and the supervision of new houses and streets, and of other matters pertaining to the health and convenience of London, are placed under the control of a Metropolitan Board, elected by the ratepayers. Their new office, in Spring Gardens, has two fronts, each 85 feet long. A magnificent scheme for the drainage of the entire metropolitan district, and to be completed by the end of 1866, embraces three levels for the north side of the river, and two levels for the south side, besides extensive outfalls. The Northern High Level, from Hampstead to Old Ford, on the Lea, is 7 to 8 miles long, including branches; the Middle High Level passes at a lower elevation, in the more crowded parts; and the Low Level will most probably be

carried under an embankment bordering the river. They terminate in the Northern Outfall of 6 miles, and a reservoir at Barking. The Southern High Level, and the Low Level, terminate in the Southern Outfall and a reservoir at Crossness Point (opposite Barking), by means of a tunnel 1 mile long, under Woolwich. The total cost has been 4,000,000*l.*, for 74 miles of sewerage. [DRAINAGE, METROPOLITAN MAIN.] From a rough calculation, it is inferred that 80 million gallons of water are supplied, daily, by the water companies within the metropolitan limits; and that within the same limits 80 million gallons of sewage are poured into the Thames from 2000 miles of sewers, containing 400 tons of solid matter fit for manure.

London requires, for its annual consumption, 270,000 oxen, 30,000 calves, 1½ million sheep, 35,000 swine, 3¾ millions of poultry, 2 million sacks of potatoes, 310,000 barrels of oysters, and 5,000,000 tons of coal.

Upwards of 3500 omnibuses circulate through London, for the most part making the City their central point. About 25 coaches and omnibuses, and 500 carriers, run from the city to places in the suburbs.

The principal markets are—The Metropolitan Cattle Market, in Caledonian Road, containing 15 acres, with 3 acres of slaughter-houses, built 1855, for the Corporation, by Bunning, at a cost of 1,460,000*l.*—Monday and Thursday, cattle; Friday, horses. Smithfield Market, 5¾ acres—Tuesday, Thursday, and Saturday, for hay. Farringdon Market, 1½ acres, in Farringdon Street, for fruit and vegetables. Newgate Market, Warwick Lane, for meat and poultry. Leadenhall Market, Gracechurch Street, for meat and poultry. Spitalfields Market, for vegetables. Corn Exchange, Mark Lane, Monday, Wednesday, and Friday. Billingsgate Market, Lower Thames Street, for fish. Bermondsey Market, for leather. Covent Garden Market, for vegetables, fruit, and flowers. Clare Market, for meat, &c. Borough Market, for fruit and vegetables. Newport Market, for poultry. Whitechapel Market, for hay.

The Bazaars are—The Baker Street; Soho Square; Pantheon, Oxford Street; Western Exchange, Bond Street; London Crystal Palace, Oxford Street; Prince of Wales', Regent Street; Portland, Langham Place; Pantechnicon, near Belgrave Square; and those in the Lowther and Burlington Arcades.

The Water Companies are the following:—New River Company; office, or works, at New River Head, Clerkenwell, and Hampstead. East London; at Bow and Lea Bridge. West Middlesex; at Hammersmith. Chelsea; at Picnic and Kingston. Grand Junction; at Kensington, Kew Bridge, and Hampton. Lambeth; at Kennington, Thames Ditton, Brixton, and Streatham. Southwark and Vauxhall; at Southwark, Battersea, and Hampton. West Kent; at Deptford, Woolwich, and Plumstead. The main pipes and branches extend 2086 miles, and it is estimated that at least 80,000,000 gallons of water are distributed daily. The head-quarters of the London Fire Brigade are in Watling Street, and the force is now under the control of the Metropolitan Board of Works.

The gas works and Companies are—British Gas Works, Old Ford; Chartered Gas and Coke Com-

pany, Horseferry Road, Westminster, Brick Lane, and Curtain Road; Commercial Gas Company, Ben Jonson's Fields; Deptford Gas Works, Creek Street; Equitable Gas Works, Thames Bank, Westminster; Great Central Gas Consumers' Company, Bow Common; Imperial Gas Works, at Maiden Lane, Hackney, Shoreditch, and Fulham; Independent Gas Works, Haggerston; London Gas Company, Westminster and Vauxhall; Phoenix Gas Works, Bankside, Blackfriars Road, and Bridge Street, Greenwich; Poplar Gas Works, King Street; Ratcliffe Gas Works, Wapping; South Metropolitan Gas Company, Surrey Canal Bridge, Camberwell; Surrey Consumers', Rotherhithe Western, Kensal Green. They produce about 5000 millions of cubic feet of gas annually, and have laid down upwards of 2000 miles of pipes.

Some of the most extensive breweries are—Barclay and Perkins', Park Street, Southwark, on a site of 10 acres; Truman, Hanbury, and Buxton's, at Spitalfields; Meux', Tottenham Court Road; Reid's, at Clerkenwell; and Whitbread's, Chiswell Street.

With respect to the London poor, the following is a list of the Unions, each of which has a poorhouse, while some have more than one, making twelve additional workhouses in all:—Bermondsey, Bethnal Green, Camberwell, Chelsea, Clerkenwell, Fulham; St. George's, Hanover Square; St. George's-in-the-East, St. George the Martyr, St. Giles and St. George, Bloomsbury; Greenwich, Hampstead, Hackney, Holborn, Islington; St. James, Westminster; Kensington, Lambeth, Lewisham, London City, London East, London West; St. Luke, Middlesex; St. Margaret and St. John, Westminster; St. Martin's-in-the-Fields, St. Marylebone; Mile End, Old Town; Newington, St. Olave's, Haddington, St. Pancras, Poplar, Rotherhithe, St. Saviour, Shoreditch, Stepney, Strand, Wandsworth and Clapham, Whitechapel. In the half year ending Lady Day, 1866, the total expenditure in the Metropolitan Division, composed of 40 unions and single parishes, or 168 parishes in all, amounted to upwards of a quarter of a million pounds sterling.

There are District Schools (composed of children from several unions uniting for the purpose), at Ealing (Central London), Anerley (North Surrey), and Peckham (South Metropolitan).

The Superintendent Registry Districts correspond, with one or two exceptions, with the Poor Law Unions, and are arranged as follows:—West Districts—Kensington, Chelsea; St. George's, Hanover Square, Westminster; St. Martin's-in-the-Fields, St. James', Westminster. North Districts—Marylebone, Hampstead, St. Pancras, Islington, Hackney. Central Districts—St. Giles, Strand, Holborn, Clerkenwell, St. Luke, East London, West London, London City. East Districts—Shoreditch, Bethnal Green, Whitechapel, St. George's-in-the-East, Stepney, Poplar. South Districts—St. Saviour, Southwark; St. Olave, Southwark; Bermondsey; St. George, Southwark; Newington, Lambeth, Wandsworth, Camberwell, Rotherhithe, Greenwich, Lewisham.

The Cemeteries for London are—City of London, Little Ilford; Tower Hamlets, Mile-end Road; North of London, Colney Hatch; Kensal Green; London Company's, at Highgate and Nunhead; Necropolis, at Woking; Islington and St. Pancras,

Colney Hatch; South Metropolitan, at Norwood; Abney Park, at Stoke Newington; Victoria Park, or East London, Bethnal Green; West London, Brompton. Bunhill Fields (28½ acres), in the City Road, is now filled with graves, and disused.

The Railway Stations round the Metropolis are—Euston Square Station, for the North-Western Railway (opened in 1838). The hall, 125 feet long, contains a statue of George Stephenson, the engineer. Paddington Station, for the Great Western line (1841), on the broad gauge. Victoria Terminus, Pimlico, the West-end Station for the Chatham and Dover, and the Brighton lines (1860). Waterloo Road Station, for the South-Western Railway (1844). London Bridge Station, for the Brighton, Greenwich, North Kent, and the Croydon and Epsom lines (1841). Fenchurch Street Station, for the Blackwall, North London, and Southend lines (1841). Shoreditch, for the Great Eastern, Southend, and North Woolwich lines (1844). King's Cross Station, the Great Northern and Midland Railways (1850). The shed is 800 feet long. Farringdon Street Station, for the Metropolitan or underground railway (1862), uniting the Great Western and Great Northern lines; and the London, Chatham, and Dover Railway. Charing Cross Terminus, and Cannon Street Station, for the South-Eastern Railway (1865–66). There are large hotels close to the stations at Euston Square, Paddington, King's Cross, Charing Cross, London Bridge, Pimlico, &c.

It is estimated that these lines now bring into London, and carry out of it, 250,000 persons daily; or seven times the number they did in 1851.

The Bridges across the Thames are—London Bridge, which is reckoned part of the Ward of Bridge Within; Westminster Bridge; Southwark; Blackfriars; Blackfriars and Cannon Street Railway Bridges; Waterloo; the Charing Cross Railway Bridge; Lambeth Bridge; Vauxhall; Battersea Bridge; Battersea Park Bridge; the Pimlico Railway Bridge, 920 feet long, on 4 arches, which leads to the new Victoria Terminus; Fulham, 786 feet; Hammersmith, 688 feet. Of some of these we supply a few additional particulars.

Waterloo Bridge has been designated the noblest stone bridge in the world; it was designed by the celebrated John Rennie, and cost above a million. The first stone was laid in 1811, and the bridge opened to the public on the second anniversary of the battle of Waterloo, June 18, 1817. It consists of nine elliptical arches of 120 feet span, supported on piers 20 feet wide at the springing of the arches. The bridge and abutments are 1380 feet long.

London Bridge, 928 feet long, with five semi-elliptical arches, was constructed by the same great architect. The first stone was laid in 1825, and the bridge publicly opened six years later. It is built of granite, and is said to have cost 2,000,000*l*. The centre arch is 152 feet span, with a rise above the water mark of 29 feet 6 inches; the two arches next the centre are 140 feet in span, with a rise of 27 feet 6 inches; and the two abutment arches are 130 feet span, with a rise of 24 feet 6 inches. The lamp posts are made from cannon captured during the Peninsular war. It has been ascertained that the number of vehicles and equestrians daily crossing the bridge in the course of twenty-four hours exceeds

20,000; and that the number of pedestrians who pass across the bridge daily during the same space of time is not fewer than 107,000.

Southwark Bridge, 708 feet long, with three cast-iron arches, resting on stone piers, was also designed by Rennie, and erected by a public company at the cost of 800,000*l*. The first stone was laid in April, 1815, and the bridge opened to the public April, 1819. The span of the centre arch is 240 feet, and the entire weight of the iron employed on the bridge amounts to 5780 tons. In July, 1866, the bridge was purchased by the corporation of London for 200,000*l*, and the charge for toll removed.

Blackfriars Bridge was the work of Robert Mylne, and originally received the designation of Pitt's Bridge, by way of a compliment to the earl of Chatham. Its first stone was laid in October, 1760, and the structure opened November, 1769. It consisted of nine arches, was 996 feet in length, and cost 152,480*l*. The foundations, however, having become decayed, the bridge has been pulled down, and a magnificent new one, by Mr. Cubitt, is being built in its place. Meanwhile, a wooden bridge, of remarkable construction, with a foot-way over the carriage-way, is temporarily used, and will probably be needed until 1868 or 1869.

Charing Cross Railway Bridge, at Hungerford, is the largest structure of the kind which spans the Thames.

Westminster Bridge, built by Mr. Page, the finest and handsomest structure of the kind in the metropolis, stands upon the site of a former erection, of which the design was due to one Charles Labelye, a Swiss. It is double the width of the old bridge, measuring 85 feet, and has seven iron arches (that in the centre having a span of 120 feet), resting upon stone piers, whose foundations descend 30 feet below low water mark. It is 1160 feet long, and the centre arch rises 22 feet above high water. The piers rest upon bearing piles of elm, driven 20 feet into the London clay, and are cased with iron piles closely united, forming a sort of permanent cofferdam. Upon these is laid a stratum of concrete, forming a foundation for the blocks of Cornish granite used in the stone-work. Its construction cost about 4*l*. per square foot.

Vauxhall Bridge, connecting Kennington and Millbank, is built of iron, and has nine equal arches. It was constructed from the designs of James Walker, was commenced May 9, 1811, and opened June 4, 1816. It is 806 feet long, 36 feet wide, and is built on caissons. The total cost of erection was 300,000*l*.

Battersea Park or Victoria Bridge is an elegant iron structure, erected in 1857, from the designs of Mr. T. Page, at a cost of 88,000*l*, and crosses the river in the neighbourhood of Chelsea Hospital and the new park at Battersea. Including the abutments it is 915 feet long, the distance between the two suspension towers being 347 feet.

Lambeth Bridge spans the river half-way between the Westminster and Vauxhall bridges. It has three equal spans of wire cables, each 280 feet wide, supporting a wrought-iron platform, and has a double carriage-way and two foot-ways; the total width being 34 feet.

The Thames Tunnel, constructed by Brunel, 1825-41, is 1200 feet long. It has been purchased by a railway company.

The wharves and quays on the Thames are about fifty in number, and from them 150 steam and other vessels arrive and depart at stated intervals.

The principal canals are the Paddington, Regent's, and Grand Surrey. For the accommodation of the river passenger traffic upwards of twenty-one steam-boat piers have been erected.

The public gardens are—Zoological Gardens and Menagerie, Regent's Park, visited by 380,000 persons in 1865; Crystal Palace, Sydenham; Botanical Gardens, Regent's Park; Cremorne Gardens, Chelsea; Belvedere Gardens, North Woolwich. Lord's Cricket Ground is at St. John's Wood; Surrey Cricket Club, at Kennington Oval. The Horticultural Society's Gardens at South Kensington, of 26 acres extent, or 500 yards by 300, have been picturesquely arranged at a cost of 100,000*l*. Here stood the building for the International Exhibition of 1862; a vast pile, 1200 feet long by 700 broad, with two domes 200 feet high and 135 feet diameter, which cost 300,000*l*.

The annual cattle show of the Smithfield Club is held in the Agricultural Hall, Islington, during the second week in December.

The chief picture galleries are—National Gallery, and the Royal Academy Exhibition, Trafalgar Square; the Vernon, Sheepshanks, Turner, and National Portrait Galleries, South Kensington Museum; Soane Museum, Leicester Square; British Institution, Pall Mall; Suffolk Street Exhibition, or Society of British Artists; Society of Painters in Water Colours, Pall Mall; Houses of Parliament Frescoes; Greenwich Hospital Naval Gallery; Crystal Palace Gallery; Dulwich Gallery; and Hampton Court Gallery.

The parks are—St. James's Park, behind Whitehall; the Green Park and Hyde Park, at the end of Piccadilly; Regent's Park, in the New Road; Victoria Park, at Bethnal Green; and the parks at Greenwich, Battersea, and Kennington. Primrose Hill, Hampstead Heath, Blackheath, Woolwich Common, and Plumstead Heath, are fine, elevated, and park-like spots in the environs of London.

The squares and open places in and near the City bounds are—Gray's Inn Gardens, Charter House Square, Temple Gardens, Falcon and Bridgewater Squares, Smithfield, Bartholomew Close, Artillery Ground, Finsbury Square, and Trinity Square, near the Tower. In Westminster are—Grosvenor (6 acres), Berkeley, Hanover, Golden, Soho, Leicester, Trafalgar, and St. James' Squares. In Belgravia—Eaton, Chester, Ebury, Eccleston, Warwick, and St. George's Squares. In Kensington is Kensington Square. At Chelsea—Sloane, Trafalgar, and Oakley Squares. At Brompton—Montpellier, Trevor, Lowndes, and Cadogan Squares. At Paddington—Sussex, Gloucester, Hyde Park, Connaught, Oxford, and Cambridge Squares. In Marylebone—Blandford, Harewood, Dorset, Montague, Bryanston, Portman, Manchester, and Cavendish Squares. In St. Pancras—Harrington, Clarendon, Clarence, York, Euston, Fitzroy, Argyle, Tavistock, Gordon, Oakley, Regent, Brunswick, and Mecklenburgh Squares. In Holborn—Bedford Square, and Lincoln's Inn Fields. In Bloomsbury—Woburn, Torrington, Russell, Bloomsbury, and Red Lion Squares.

P. *Metropolitan Improvements*.—Of late years a great effort has been made to improve the appearance

and embellish the architecture of London; to open up new and splendid thoroughfares; to remove unsightly excrescences; to take advantage of favourable sites for the erection of noble edifices; and generally to render it the handsomest, as it is indubitably the wealthiest and most populous city in the world. To enumerate all these great public improvements would be impossible in our narrow limits. The greatest, the embankment of the river Thames, is fully described in the article EMBANKMENT OF THE THAMES. The Holborn Valley Viaduct, an undertaking which has been contemplated for at least fifty years, has at last been commenced, and when completed will add very materially to the facilities for traffic in that part of the metropolis.

Q. General Enumeration of Public Objects, &c.—In the City, the Monument, Fish Street Hill (built in 1677 by Wren, after the Great Fire), a Doric column, 202 feet high; Edward VI., at Christ's Hospital and St. Thomas' Hospital; Queen Elizabeth, St. Dunstan's, Fleet Street; William III., in the Bank; Queen Anne, St. Paul's Church Yard, and Queen's Square, Bloomsbury; William IV., King William Street, London Bridge; Queen Victoria, in the Exchange, by Lough; Duke of Wellington, opposite the Exchange, and in the Tower. At the West End are—Charles I., Charing Cross; Charles II., Soho Square; James II., Whitehall Yard; William III., St. James' Square; George I., Leicester Square, Grosvenor Square, and Bloomsbury Church; George II., Golden Square; George III., Cockspur Street; George IV., Trafalgar Square; Queen Victoria, Piccadilly; William duke of Cumberland, Cavendish Square; Duke of York, a column, 137 feet; Wellington, opposite Apsley House, Piccadilly; Nelson, a column, 162 feet high; General Napier, Havelock, and Jenner, in Trafalgar Square; Pitt, Hanover Square; Canning, Palace Yard; Richard Coeur de Lion, New Palace Yard, by Marochetti; Duke of Bedford, Russell Square; Fox, Bloomsbury Square; Duke of Kent, Portland Place; Major Cartwright, Burton Crescent; Captain Coram, Foundling Hospital; George Stephenson, Euston Square Station; Achilles Statue, in Hyde Park, in commemoration of the Battle of Waterloo; Guards' Memorial of the Battle of Inkermann, Waterloo Place; Westminster Memorial, in Dean's Yard. The Marble Arch, Hyde Park, was the entrance gate of Buckingham Palace.

There are about seventy churches in the city, some of the most remarkable of which, after St. Paul's Cathedral, are—Allhallows, Barking; St. Andrew, Undershaft; St. Antholin; St. Bartholomew the Great; St. Stephen's, Wallbrook, by Wren, restored 1852; St. Bride's, Fleet Street, by Wren, steeple 226 feet high; St. Dunstan's in the West; St. Giles', Cripplegate; St. Mary, Aldermanbury, by Wren; St. Mary-le-Bow, or Bow Church, Cheapside, by Wren, spire 239 feet high, and Norman crypt; St. Mary Woolnoth; St. Michael, Cornhill, by Wren, lately restored; St. Olave's, Hart Street; St. Swithin's, and the London Stone; St. Vedast, Foster Lane; Dutch Church, Austin Friars. The richest livings are St. Botolph, Bishopsgate, value 2290*l.*; St. Olave, Hart Street, 1891*l.*; St. Giles, Cripplegate, 1589*l.* The lowest is St. Bartholomew the Less, 30*l.* Fuller details of some of the more remarkable of these

public edifices have been already given in preceding portions of this article.

R. Legal Courts.—The principal courts of law, viz., the Courts of Chancery, Queen's Bench, Common Pleas, and Exchequer, have their first seat at Westminster Hall, within the verge of the new palace of the sovereign (or Houses of Parliament); and from hence they are adjourned to the Courts in Chancery Lane, and the City Courts at Guildhall. The Central Criminal Court is at the Old Bailey, near Newgate. The County Sessions Court, at Clerkenwell, is a handsome building, lately restored. The Bankruptcy Court, Basinghall Street, was rebuilt in 1820. The Courts of Probate, Divorce, and Matrimonial Causes, are held in Westminster Hall, where the High Court of Admiralty is, for the present, also held. The Inns of Court and of Chancery are as follow:—the Inner and Middle Temple, in Fleet Street, near Temple Bar, on the site of a preceptory of the Knights Templars, of which the Norman Round Church, built in 1185, remains. In the grounds and gardens are the Judges' Lodgings, Inner and Middle Temple Halls and Libraries, including the new Gothic Library, opened by the prince of Wales in 1861. Clifford's, Lyon's, Clements, and New Inns of Chancery, are members of the Temple. Lincoln's Inn, between Chancery Lane and Lincoln's Inn Fields, includes the Lord Chancellor's and Vice-Chancellor's Courts, a hall, restored in the Tudor style, library, and chapel. Furnival's and Thavies' Inns of Chancery were members of Lincoln's Inn. Gray's Inn, Holborn, includes a hall and chapel, and has Barnard's and Staple's Inns of Chancery for its members. The Rolls Court (including the old Rolls Chapel, Master's House, and Judge's Chamber, in the gardens, with the new Repository behind it, in the Tudor style), and Sergeant's Inn and Chapel, are in Chancery Lane. The College of Advocates, or Doctors of Civil Law, is at Doctors' Commons. A new Palace of Justice, which when completed will be one of the finest and most convenient buildings of the kind in the world, is about to be erected between Temple Bar and St. Clement's Church. Many of the courts, especially those which are now held at Westminster Hall, will be removed here.

The Metropolitan Sessions of the Central Criminal Court are held monthly, at the Old Bailey. Its jurisdiction is continuous with the City of London, the county of Middlesex, and the places within the Metropolitan Police district, in the counties of Essex, Kent, and Surrey, respectively. Courts of Quarter Sessions are held four times a year at the Old Bailey and Guildhall, for the City; Wellclose Square, for the Tower Liberty; Bridge House Hotel, for Southwark; Clerkenwell Sessions House, for Middlesex; Westminster Guildhall, Broad Sanctuary, for Westminster; County Gaol, Horsemonger Lane, for Surrey. The parishes on the borders of the Metropolitan Police district are arranged into eighteen petty sessional divisions.

The Metropolitan Local Courts are—Lord Mayor's Court, Guildhall; a Court of Record, with a jurisdiction extending to all places within the City and Liberties. A Court of Hustings was granted by Edward the Confessor, from whom the City received its earliest charter. The Sheriff's Court, held at Guildhall Buildings, comprises the City and Liberties,

with the precincts and extra-parochial places adjoining. The jurisdiction of the Southwark Borough Court of Record includes the parishes of St. Saviour (except the Clink Liberty), St. George, St. John, St. Olave, and St. Thomas. The Westminster Local Court is held at the Guildhall, Westminster. The City Court for the recovery of debts, is the Sheriff's Court, Guildhall.

The Metropolitan County Courts without the City are as follows:—The Westminster, St. Martin's Lane; Marylebone, Marylebone Road; Brompton, Chelsea; Clerkenwell, Duncan Terrace, Islington; Shoreditch, Charles Square, Hoxton; Whitechapel, Great Prescott Street; Bow, Bow Road; Bloomsbury, Great Portland Street; Southwark, Swan Street, Borough; Lambeth, Camberwell New Road; Greenwich, Church Street.

The London District Court of Bankruptcy comprises the City, and the counties of Middlesex, Beds, Berks, Bucks, Cambridge, Essex, Hants, Herts, Hunts, Kent, Norfolk, Northampton, Oxford, Rutland, Suffolk, Surrey, Sussex, all places in the S. division of Wilts; and the following places in the county of Dorset, viz.—Poole, Wimborne Minster, Blandford, Sturminster, Shaftesbury; and all other places in that county within a hundred miles of the General Post Office.

The Registry of Deeds and Conveyances, Wills, Judgments, &c., for Middlesex, is in Bell Yard, Temple Bar.

History and Chronology.—London is a city of great antiquity. According to some authorities, a settlement existed on its site 1107 years before the birth of Christ, and 354 years before the foundation of Rome; but putting aside all doubtful speculations, it is sufficient to date its records from 54 B.C., when it was the capital of the Trinobantes, and the royal seat of their sovereigns. In A.D. 61 it was occupied by the Romans as Londinium, or Colonia Augusta, and distinguished as the resort of native and foreign merchants. The Romans built a strong wall around their possession, which had four principal gates, and which by successive generations was enlarged, repaired, and strengthened. Numerous additional gates were also erected to meet the exigencies of a rapidly increasing population. In the Saxon era, Lundenceaster was the capital of the Saxon state of Essex, and it became the capital of the kingdom upon the downfall of the Heptarchy. After the Norman conquest it rapidly grew in prosperity and power. Its first charter was granted by William the Conqueror; but to write its annals, even in their most condensed form, would occupy a much larger space than we have at our command, and we can only supply a few of their leading incidents in chronological arrangement:—

Bishopric of London founded by Mellitus,	604
London plundered by the Danes,	839
Alfred repairs and strengthens the city,	884
The Tower built by William I.,	1078
First charter granted by the same sovereign,	1079
A great fire; St. Paul's burnt,	1086
London Bridge built, 1014; burnt,	1136
Old London Bridge begun,	1176
Henry Fitz-Alwyn, the first mayor,	1189
Charter granted by Henry II.,	1154
First stone bridge completed,	1209

Charter of King John; mayor and common council to be elected annually,	1214
Aldermen appointed,	1242
Livery companies incorporated,	1327
Charter granted by Edward III.,	1328
Terrible plague; 50,000 people perish,	1348
London first sends members to Parliament,	1355
William of Walworth, lord mayor,	1380;
Wat Tyler's rebellion,	1381
Guildhall begun, 1411; finished,	1416
Whittington thrice lord mayor, 1397, 1406,	1419
Jack Cade's rebellion,	1450
Caxton sets up his printing press,	1471
Streets first paved,	1553
St. Bartholomew's Priory converted into an hospital,	1539
Coaches introduced,	1563
Exchange built,	1566
New River water introduced,	1613
Hackney coaches first plied,	1625
Child's Bank established,	1660
The Great Plague kills 68,596 persons,	1665
The Great Fire,	1666
Monument erected,	1671-77
Bank of England established,	1694
Bank of England built,	1732-34
Blackfriars Bridge opened,	1769
Lord George Gordon's No-Popery riots,	1780
Gas first exhibited in Pall Mall,	1807
The Mint finished,	1811
Gaslight becomes general,	1814
Waterloo Bridge opened,	1817
Southwark Bridge opened,	1819
Cabs introduced,	1823
Omnibuses begin to ply,	1829
New Post-office completed,	1829
New London Bridge opened,	1831
Fearful visitation of cholera,	1831-32
Houses of Parliament burnt,	1834
Royal Exchange burnt,	1838
Penny postage begun,	1840
Thames Tunnel opened,	1843
Royal Exchange opened,	1844
Penny steamboats begun,	1845
Great Chartist demonstration,	1848
Second attack of cholera,	1849
Great Exhibition opened, May 1; closed,	
October 11,	1851
Third attack of cholera,	1854
Metropolitan Board of Works established,	1855
Metropolitan Underground Railway begun,	1860
International Exhibition opened, May 1,	1862
Metropolitan railway opened,	1863
Charing Cross railway opened,	1864
Mr. Peabody's gifts of 250,000 <i>l.</i> to the London poor,	1862 and 1866

(For further particulars relative to London, the reader is referred to the elaborate works of Stow, Maitland, and Pennant; *Chronicles of London Bridge*; *History of the Temple Church*; G. G. Scott's *Memoirs of Westminster Abbey*; Charles Knight's *London*; *Londiniana*, by E. Brayley; *London, Past and Present*, by Peter Cunningham; *Lysons' Environs of London*; Faulkner, *History of Chelsea*; Morant, *History of Essex*; *Gentleman's Magazine*; and *Handbooks to London*, published by Murray, Black, Cruchley, and Chambers.)

LONDON CLAY (Geology). The name given to a tenacious bluish clay which occurs under and in the vicinity of the metropolis, varying from 200 to 350 feet in thickness. Its stratigraphical position is about the top of the Eocene Tertiary, the earliest formation of the great Tertiary Group. It is associated with the Bognor and Woolwich beds and the Thanet sands. It contains numerous bands of *septa*, and abounds in marine shells, crustacea, teeth of sharks, bones of other fishes, reptiles, birds, trunks of trees, &c. The London Clay is believed to mark an age when the climate was much milder in England than it is now.

LONDON, NEW. [CONNECTICUT.]

LONDON UNIVERSITY. [UNIVERSITY OF LONDON.]

LONDONDERRY, a county of the province of Ulster, in Ireland, bounded N. by the Atlantic Ocean, E. by Antrim and a portion of Lough Neagh, S. by Tyrone, and W. by Donegal. It lies between $54^{\circ} 38'$ and $55^{\circ} 22'$ N. lat., $6^{\circ} 28'$ and $7^{\circ} 24'$ W. long. The greatest length N. to S. is 40 miles; the greatest breadth E. to W. is 34 miles. The area is 810 square miles, or 518,595 acres, of which 318,282 are arable, 180,709 uncultivated, 7718 in plantations, 1559 in towns and villages, and 10,327 under water. The population in 1861 numbered 184,209 (in 1851, 191,868), of whom 83,402 were Roman Catholics, and 31,218 belonged to the Established Church.

Surface and Rivers.—The county is of an irregularly triangular area. From the Bann the surface gradually rises westward for about 10 miles, forming a chain of elevations which bound the valley of that river on the west. Westward of these elevations is an extensive tract of undulating country, extending from their bases to the eastern shore of Lough Foyle, and bounded on the south by the mountain range which separates the counties of Londonderry and Tyrone.

The Lower Bann, from Lough Neagh to the sea, a distance of upwards of 30 miles, has a fall of only 48 feet. The general characteristics of this district are similar to those of the north coast of the county of Antrim. The elevations are, however, inconsiderable, and the general aspect of the country is tame and bleak. West of the sandbanks which occur at the embouchure of the Bann the coast has a bolder outline, rising in a series of precipitous cliffs over the sandy beach. Among the loftiest basaltic cliffs are Benbradagh, 1531 feet high, and Craignashock, 1773 feet high. West of the valley of Ballynascreen commences a mountain chain, which with little interruption extends to the valley of the river Foyle, forming the boundary between the counties of Tyrone and Londonderry. Its chief heights are Sawell, 2236 feet high; Muinard, 2057 feet high. The district included between these mountains and Lough Foyle, constituting the western division of the county, is divided by a central tract of high land into the valleys of the rivers Roe and Faughan.

Between the Lower Faughan and the Foyle is a range of undulating ground crossed by a valley, through which the high road, leading over a bridge, completes the communication with Londonderry city.

The most remarkable feature of the coast line is the tract which extends from the north-western

extremity of the hilly region to the low point of Magilligan and southward to the mouth of the Roe. On this tract is measured the base-line of the trigonometrical survey of Ireland, 53,200 feet in length. The same tract appears to occupy the greater portion of the bottom of the lough, and rises towards its centre in a bank which confines the navigation to that portion of Lough Foyle lying along the coast of Donegal. The lough is about 18 miles long by 10 broad. The entrance to the lough, between Magilligan Point and Ennishowen Head, is about a mile across, and from this point to Londonderry city is a safe and tolerably sheltered navigation of 23 miles. Eastward of the entrance is a shoal called the Tuns, which renders the lough difficult of access in stormy weather.

The chief rivers of the county are the Bann, Foyle, Macosquin, Agivey, Clady, Mayola, Ballinderry, Roe, Faughan, Owenreagh, and Owenbeg. The roads of Londonderry are generally excellent. There are no canals.

Geology, Soil, Productions.—The basaltic tract, which forms the eastern section of the county, corresponds in all respects to the remainder of the field on the Antrim side of the Bann [GIANTS' CAUSEWAY], with this remarkable difference, that the dip of the strata is reversed. The geological structure of the district may be described as a floor of primitive rock overlaid in part by a field of secondary formations, capped by basalt. The main constituent of the western section is mica slate. Primitive limestone occurs in many places; and on the east side of Slieve Gallion there is a granular limestone, which contains quantities of crystallized hornblende: hornblende slate is found at several places in the valley of the Roe. The structure of the south-eastern extremities of the county is more complex, the varieties of formations which appear at the surface being numerous. There are no mines worked in this county.

The soil of that part of the valley of the Bann where the subsoil is hard basalt, consists for the most part of a rusty loose grit, without sufficient strength or cohesion for wheat crops. Numerous tracts of bog, interspersed with shallow pools, and frequently separated by craggy knolls of basalt, are scattered over this part of the county. There are, however, tracts of good land along the banks of the several rivers which traverse the district, and especially at their junctions; and between the basalt and the primitive district farther west is a tract of rich open country, extending southward into Tyrone. This is the most extensive tract of good ground in the county. The best improved portions of the county are the district of Lough Neagh, the valley of the Roe, the valley of the Faughan, and the immediate vicinity of Londonderry on both sides of the Foyle. There is a very general scarcity of timber.

The progress of agriculture in this county has been materially forwarded by the establishment of an agricultural school near Muff by the Company of Grocers of London, who here hold large estates under the Crown. Oats and barley are the principal grain crops. In 1862, 297,239 acres of arable ground were cultivated. There is but little land in pasture, and the breed of cattle, as well as of pigs, of which great numbers are reared, forms a principal staple

of the wealth of the county. In 1862 the number of cattle was 93,902; sheep, 26,285; pigs, 28,214.

The manufacture and bleaching of linens is the chief trade of Londonderry. The most extensive bleach-greens lie along the rivers Roe and Faughan, on the latter of which there are abundant water-power and numerous sites admirably calculated for this branch of manufacture. The weavers and flax-dressers are numerous. The export and import trade of the county is carried on at the ports of Londonderry city and Portrush, the latter being the seaport of Coleraine.

Divisions and Towns.—Londonderry is divided into six baronies, containing altogether forty-three parishes. It is chiefly in the diocese of Derry and Raphoe. It is in the North-Western Circuit, and the assizes are held in the city of Londonderry. The county returns two members to Parliament; one is returned for the city of Londonderry, and one for the town of Coleraine. The number of parliamentary electors in the county in the year 1865 was 5512.

The following are the principal towns, with the population of each in 1861:—

Coleraine is a parliamentary borough and port, situated 4 miles from the sea, on both sides of the Bann, over which is an excellent stone bridge of three arches. The town consists of a central square, and several diverging streets on the east bank of the river and in the county of Antrim, and a portion on the west bank called Waterside, or Killowen. It contains a town-hall, a market-house, four parish churches, two Roman Catholic chapels, four Presbyterian chapels, and three or four other chapels. A fine linen called Coleraines is made here, and there are paper, soap, leather, and other manufactures. Vessels of 200 tons' burthen can discharge at the quay, and a brisk trade, chiefly by steam, is carried on with Liverpool through Portrush, the shipping port, 2 miles E. from the mouth of the Bann, and 6 miles from the town. The borough returns one member to Parliament. Population 5631, including about 250 parliamentary voters. The number of vessels which entered the port in 1864 was 413 (66,689 tons), and the clearances 162 (34,851 tons). The customs revenue in 1865 was 5442*l*.

Dungiven is a small town situated in a rich and sheltered vale watered by the Roe, about 17 miles W. by S. from Londonderry. Population, 845.

Kilrea is a small town on the west bank of the Bann, about 15 miles S. by E. from Coleraine. Population, 924.

Londonderry, commonly called *Derry*, a county of a city, parliamentary borough, municipal borough, and seaport, in 54° 59' N. lat., 7° 19' W. long., 144 miles N.N.W. from Dublin, is situated on an oval-shaped hill, 119 feet above high water, which projects into the Foyle from the western bank, and 5 miles above the entrance of the river into the estuary called Lough Foyle. The city is surrounded by an ancient wall, a mile in circumference, with six gates, beyond which the houses have been considerably extended. The streets radiate from a central square, and some of them are very steep. A wooden bridge 1068 feet long connects the city with the suburb of Waterside, on the eastern bank of the river. The principal public buildings are—the corporation hall, custom house, county and city court

house, prison, lunatic asylum, the cathedral and two other Protestant churches, two Roman Catholic, six Presbyterian, and three Methodist chapels. There are several flour mills, two flax-spinning mills, three distilleries, two breweries, and two large rope-walks. The assizes for the county are held in the city. The river is at all times navigable for large vessels, and small craft can proceed about 7 miles higher, to Johnstown village, and barges by a canal to Strabane, 14 miles. The quays are commodious, and allow vessels of 500 tons' burthen to discharge at them. The port has some foreign and colonial trade; the coasting trade is considerable, and there are seven steamers which ply to Liverpool, Glasgow, Greenock, Ardrossan, and Campbeltown. The number of vessels which entered the port in 1864 was 1313 (229,843 tons), and the clearances 710 (155,114 tons). The customs revenue in 1865 was 104,092*l*. The municipal borough is divided into three wards, and is governed by six aldermen and eighteen councillors. Population, 20,875. The city returns one member to Parliament, the number of voters being about 850. The chief event in its history is its gallant resistance of the forces of James II. in 1689, during a siege of 105 days, commemorated by a column in honour of the Rev. George Walker, at that time its governor.

Magherafelt is an improving town, with a sessions-house, union workhouse, and markets for linen, and very large monthly cattle fairs. It is situated 4 miles W. from the north-western angle of Lough Neagh. Population, 1293.

Newtown Limavady, a market town, 16 miles N.E. from Londonderry, is situated on the east bank of the river Roe, and comprises three tolerably well-built streets, and others not so good. It contains a market-house, union workhouse, a handsome church, and other places of worship. The town is respectably inhabited, and has a good retail trade. Population, 2732.

History and Antiquities.—At the most remote period this county appears to have been possessed by the septa of O'Loughlin and O'Neill. The establishment of an English garrison at Coleraine enabled the English very soon after to reduce at least the eastern and central parts of the county into shire ground. It is probable that the English law continued in force in the eastern parts of the county until the great revolt of the O'Neills in 1333. After that period the native Irish continued undisturbed masters of the country until the middle of the sixteenth century, when the rebellion of Shane O'Neill, in 1566, made it necessary to send a force to Derry. In the year 1600, Sir Henry Dockwra, with an efficient force, constructed three forts in the county; and this was the first commencement of a permanent settlement. The rebellion of Sir Cahir O'Dogherty in 1608, and the flight of Tyrone and O'Donnell in the preceding year, left the entire of this and five other counties at the disposal of the Crown. On the 28th January, 1609, negotiations were commenced between the king and the corporation of London for the purpose of settling the terms on which the forfeited lands in this county should be conveyed to the latter for the purpose of planting them with Protestant colonists. It was at first agreed that the Londoners should spend 20,000*l*. on the plantation, in consideration of which the king granted to them the old county and

town of Coleraine, with the woods of Glanconkne and Killeightra, and the town and liberties of Derry, excepting the church lands. The corporation still retains these estates, whose management is vested in a body of twenty-six, consisting of a governor, deputy-governor, and assistants, of whom one-half retire annually. In 1619 this body was incorporated by royal charter, and their estates erected into one county, hence called the county of Londonderry. Some parts of the county, however, were assigned to the civic companies. The introduction of the new colony changed the entire face of the country, which up to this period had been one of the most desolate tracts in Ireland.

There are some remains of a Cyclopean fortress at the Giant's Sconce, on the road from Newtown Limavady to Coleraine. Dungorkin is a circular mount, surrounded by a wet ditch, near Claudy. There are several cromlechs, druidical remains, caves, and tumuli. Of military edifices the only remaining are the castles of Killaloe, Dungiven, Salterstown, and Muff. The old abbey of Dungiven, which occupies a romantic site on a rock rising 200 feet above the bed of the river Roe, and the old church of Banagher, are the chief ecclesiastical remains.

LONDONDERRY, CHARLES WILLIAM STEWART, MARQUIS OF, was born in 1780, and received a commission in the 108th Foot, at the age of fourteen. In 1796 he joined the expedition under the earl of Moira, which was destined to relieve the duke of York in Flanders. On the return of the British army he was attached to Colonel Charles Crawford's mission to the Austrian armies in 1795-97; and at the battle of Donauwert was severely wounded. On his return to England he passed rapidly through the different grades of military rank, until he was appointed to the lieutenant-colonelcy of the 18th Light Dragoons. He was soon afterwards engaged in the expedition to Holland under Sir R. Abercromby, and highly distinguished himself in the attack on the enemy's positions in September, 1799. In 1803 he was made a colonel in the army, and soon afterwards assumed the command of a brigade of Hussars under Sir J. Moore, in Portugal. In 1809 Brigadier-general Stewart was appointed adjutant-general to the army under Sir Arthur Wellesley, in which capacity he highly distinguished himself during the pursuit across the Douro of the French army, under Marshal Soult. At Talavera the most honourable mention was made of his services. He also served with distinction, in 1812, at Busaco and Ciudad Rodrigo as adjutant-general. After the fall of the latter place the marquis obtained leave to return to England. In 1820 he was nominated to the command of the 10th Hussars. In 1837 he obtained the rank of general in the army; and in 1843 he was removed to the command of the 2nd Life Guards. On the death of the duke of Wellington, in 1858, he was created a Knight of the Garter. He died in 1854.

LONDONDERRY, ROBERT STEWART, MARQUIS OF, better known in history as Lord Castlereagh, was born at Mount Stewart, county Down, Ireland, June 18, 1769. He derived his title, which is Irish, from his father. He was educated at the grammar-school of Armagh and St. John's College, Cambridge. In 1789 he was returned to the Irish House of Commons for Downshire, in the Reform

interest, to which he pledged himself, but changed his politics about four or five years after, and went over to the Tories. He made his maiden speech in the English House of Commons, to which he had been returned for the borough of Tregony, October 29, 1795, in seconding the address. He vacated his seat in July, 1797; upon which he was re-elected to the Irish Parliament for the county of Down, and was made Keeper of the Privy Seal for Ireland. In the beginning of 1798 he was made Secretary to the Lord Lieutenant and an Irish privy councillor. From this date he may be regarded as having been distinctly the ministerial leader in the Irish Commons, and he was, no doubt, one of the principal promoters of the union, which took place two years after. He sat for the county of Down in the Imperial Parliament from 1801 until 1805, when he was promoted from the presidency of the Board of Control to be Secretary of State for the department of War and the Colonies. He resigned his office on the death of Mr. Pitt, but resumed it on the commencement of the Portland administration. He had meanwhile been returned for the borough of Plympton, Devonshire. The failure of the Walcheren expedition not only made him very unpopular, but involved him in a personal quarrel with Mr. Canning, who was severely wounded in the duel that resulted from it.

Lord Castlereagh, on the resignation of the Marquis Wellesley, was appointed Secretary of State for the Foreign Department. To the Parliament which met in November, 1812, he was returned for the county of Down; and he also retained that seat in the next two Parliaments.

Meanwhile in 1813 he went as British plenipotentiary to the negotiations opened with the French government at Châtillon; he also appeared as representative of the king of England at the peace of Paris, in May, 1814; at the congress of Vienna, in October of the same year; at that of Paris after the battle of Waterloo; and at that of Aix-la-Chapelle in 1818. He was made a Knight of the Garter in 1818, and became Marquis of Londonderry by the death of his father on the 8th of April, 1821.

Lord Londonderry died by his own hand at his seat of North Cray Place, in the county of Kent, on the 12th of August, 1822. A verdict of lunacy was returned by a coroner's jury.

LONG ISLAND. [NEW YORK.]

LONG VACATION, or lawyer's holiday, is a term when lawsuits are suspended in the English courts. In common law it is from the 10th of August to the 24th of October, and in Chancery to the 28th of October in every year.

LONGFORD, an inland county of the province of Leinster, in Ireland, bounded N.W. by Leitrim, N.E. by Cavan, S.E. by Westmeath, and S.W. by Roscommon. It lies between 53° 29' and 53° 56' N. lat., and 7° 19' and 7° 56' W. long. Its greatest length N. to S. is 29 miles; its greatest breadth E. to W. is 22 miles. The area is 420 square miles, or 269,409 acres, of which 191,823 are arable, 58,937 uncultivated, 4610 in plantations, 364 in towns and villages, and 13,675 under water. In 1861 the total number of inhabitants in the county was 71,592, of whom 64,810 belonged to the Roman Catholic Church, and 6114 to the Establishment. In 1851 the total population was 82,350.

Surface and Rivers.—The general slope of the surface is westward and south-westward towards the Shannon, except in the north-eastern angle towards Cavan, where the county embraces a small portion of the basin of Lough Erne. This district, forming the immediate basin of Lough Guounagh, is separated from the remainder of the county by a slightly elevated tract upon the south, and by a series of hills of low elevation on the west. Lough Guounagh is a very irregular piece of water, extending about 5 miles each way, but is rather a collection of lakes communicating by narrow channels than one sheet of water. Its chief feeders are small streams running from the surrounding hilly country. The hills called the Cairn Clonhugh present several summits nearly 1000 feet high. Between their western termination and the Shannon lies an open well-cultivated tract, while their south-eastern slope forms one side of the fertile and prosperous valley of the Camlin. The district between the Keenagh and the Shannon, which along the south-western boundary of this county expands into the extensive lake of Lough Ree, is very flat and boggy. An inlet of the lough, running about 4 miles eastward from the main sheet of the lake, bounds this part of the county on the south. Near the shore in this direction lie the small lakes of Derry and Derrymacar. The valleys of the Camlin and Inny are separated by a low tableland, rising into only one conspicuous eminence of 650 feet at Slieve Goldry. The only striking natural feature in this part of the line is Glen Lough, a sheet of water about a mile and a half in length.

The Shannon bounds the county on the west. The other rivers are the Clonard, Rinn, Camlin, Keenagh, and Inny. The Royal Canal runs through the county.

Geology, Soil, Productions.—The entire district south of the Camlin consists of floetz limestone, with the exception only of two patches of sandstone. The immediate valley of the Camlin on its southern bank, and the entire tract extending northward from it to the county of Leitrim, consist of clay-slate. Between these lies a belt of yellow sandstone and conglomerate. The low gravel region, in which the eskers occur, contains large quantities of fine calcareous sand and marl. Marly clay also underlies many of the boggy tracts. A little millstone grit appears. Iron, coal, lead, and marble are among the mineral products. In the tract sloping towards the valley of the Inny is a rich vegetable mould, producing either heavy grain crops or sweet fattening pasture. The rest of the county is chiefly grazing land. Great quantities of butter are made by the farmers and cottiers. Pigs are reared in great numbers, namely, 13,775 in 1862.

The linen manufacture is carried on with some activity in the neighbourhood of Newtown Forbes, where the first Earl of Granard took pains to introduce it. The manufacture of coarse flannels and friezes for home consumption is also carried on throughout the county.

Divisions and Towns.—The county of Longford is divided into six baronies, containing twenty-six parishes in all. It is in the diocese of Kilmore, Elphin, and Ardagh. It is in the North-Western Circuit, and the assizes are held at Longford. The county returns two members to Parliament. The number of electors on the county register in the year 1865 was 2767.

Ardagh is a small village, about 10 miles S.E. from Longford. It was formerly the seat of a separate bishopric, but is now included in the united bishopric of Kilmore, Elphin, and Ardagh.

Ballymahon, a market town, 12 miles S. by E. from Longford, is situated on the river Inny, which falls into Lough Ree about 3 miles W. from the town. The town consists chiefly of one very wide street, and contains a sessions-house, a church, a Roman Catholic chapel, and 1130 inhabitants. Oliver Goldsmith spent much of his early life here.

Granard, a market town, 14 miles N.W. by W. from Longford, contains a sessions-house, a union workhouse, a church, and a Roman Catholic chapel. The market receives weekly a large quantity of agricultural produce, but the trade of the town in other respects is not flourishing. Population, 1671.

Longford, the capital of the county, 76 miles N.W. by W. from Dublin, is surrounded by an extensive plain of bog, swamp, pasture land, and arable land. It is watered by the small river Camlin, which falls into the Shannon four miles westward from the town. A branch from the Royal Canal terminates at Longford. The town consists of regular streets, and contains a county court-house, county prison, union workhouse, barracks, a handsome church, a very fine Roman Catholic chapel of recent erection, and two or three places of worship for Dissenters. The assizes are held in Longford. The population in 1861 was 4872.

History and Antiquities.—The territory at present constituting the county of Longford was originally a portion of the kingdom of Meath, and as such was included in the grant of Meath by King Henry II. to Hugh de Lacy. On the erection of the district into a separate county, in the eleventh of Elizabeth, it retained few or no traces of ever having been under the authority of the English law or government. A reparation out of the county took place in 1615. The plantation did not take effect to any great extent, as in 1641 the entire county appears to have been temporarily recovered by the O'Farrells, excepting only Longford Castle and Castle Forbes. The confiscations which ensued extended over nearly the entire county, and introduced almost totally a new proprietary.

Among the antiquities is the rampart of Duncla, which extends 8 miles. On the island of Inch-Clorin, in Lough Ree, moulder the ruins of seven churches, and the foundation of a round tower. An abbey was established here, about 540, by St. Dermid. The remains of another round tower may be seen at Granard. The abbey at Longford was one of Patrick's foundations; on its site a fine monastery was built in 1400, the church of which is now the parish church. There are remains of the religious houses of Moydow, Clonebrone, Clone, Derg, and Innismore, a foundation of St. Columba's, on an island in Lough Guounagh. A few castles are still partially standing, of which the principal are at Castle-Forbes, Granard, Tenallick, Castlecro, Ratheline, and Ballymahon.

LONGICORNES, the fourth family of the tetramorous Coleoptera in Latreille's arrangement of insects. It includes a vast number of large and beautiful beetles, all remarkable for the length of their antennæ, which in many species are several

times longer than their bodies. They inhabit woods, where the females deposit their eggs beneath the bark of trees, effecting the operation by means of a long, strong, horny ovipositor with which they are provided. The females are usually larger than the males. The larvæ live beneath the bark of trees or in the wood, in which they bore deeply, and do much damage. The greatest assemblage of species and the largest forms are found in South America; but longicorn beetles are very generally dispersed. This family is divided into three great groups, of which the genera *Prionus*, *Cerambyx*, and *Leptura* are the respective types.

LONGINUS, the author of a treatise in Greek 'On the Sublime,' is said to have been born either in Syria or at Athens. His education was carefully superintended by his uncle Fronto, a celebrated teacher of rhetoric; and he also received instruction from Ammonius and Origen. He afterwards settled at Athens, where he taught philosophy, rhetoric, and criticism, and numbered among his disciples the famous Porphyry. He finally removed to Palmyra at the invitation of Queen Zenobia, to superintend the education of her sons, and took an active part in public affairs. After the capture of Palmyra by Aurelianus, in 273, Longinus was put to death by order of the emperor.

There is some doubt whether the treatise 'On the Sublime' (*περὶ ὑψηλοῦ*) was written by this Longinus. It has for its object the exposition of the nature of the sublime, both as to the expression and the thought, which the author illustrates by examples. As a specimen of critical judgment the work has always maintained a high rank, and in point of style is perspicuous and precise.

LONGIPENNES, Cuvier's family name for the long-winged oceanic birds, such as the *Petrels*, *Albatrosses*, &c. The genera which he includes in this family are *Procellaria*, *Puffinus*, *Halodroma*, *Pachyptila*, and *Diomedea*.

LONGIROSTRES, Cuvier's name for a family of wading birds, in which he includes the genera *Ibis*, *Namenius*, *Scelopax*, *Rhynchœa*, *Limosa*, *Calidris*, and *Tringa*, *Arenaria*, *Pelidna*, *Falciuella*, *Machetes*, *Hemipalama*, *Eurimorhynchus*, *Phalaropus*, *Strepsilas*, *Totanus*, *Lobipes*, and *Himantopus*, the greater part of which would come under the family *Scolopacidae*. He remarks that one can hardly place the *Avosets* (*Recurvirostra*, Linnæus) in any other position than at the end of the *Longirostres*.

LONGITUDE and LATITUDE. These terms mean different things as applied to a point of the earth, or a star in the heavens; and we must accordingly distinguish between *geographical* latitude and longitude, and *celestial* latitude and longitude.

The latitude of a star in the heavens is its angular distance from the ecliptic, measured on a great circle drawn through the star and pole of the ecliptic. It differs from the declination only in this, that the ecliptic is used instead of the equator. The longitude of a star is the angle made by the circle on which latitude is measured with the circle which passes through the pole of the ecliptic and the vernal intersection of the equator and ecliptic. Thus a star on the ecliptic has no latitude, and one which lies directly between a pole of the ecliptic and the vernal equinox has no longitude. The use of celestial

longitudes and latitudes has in great measure been superseded by those of right ascensions and declinations.

The meaning of the term *geographical* longitude is the same whether we consider the earth as a sphere or a spheroid. It is the angle contained between the plane of the meridian of the place, and that of some one meridian which is fixed on as the starting-place. Thus, we choose the Observatory of Greenwich, and the French that of Paris, as being in the first meridian; and while we express the relative position of the two observatories (in longitude) by saying that Paris is $2^{\circ} 20' 24''$ east of Greenwich, the French describe Greenwich as $2^{\circ} 20' 24''$ west of Paris.

It is usual to measure terrestrial longitudes in time, the whole circuit of the globe being supposed described (as in the diurnal motion) in twenty-four hours. It is also usual to reckon longitudes to 180° east or west, without proceeding farther. Thus a motion in longitude of 185° east will bring the traveller into 175° of west longitude. In astronomical writings, however, longitudes (both geographical and celestial) are measured all round the globe.

Supposing the earth to be a sphere, the latitude of a place is the angle subtended at the centre by the arc of the meridian intercepted between the place and the equator. This angle is equal to the altitude of the pole of the heavens at the place; and the determination of the altitude of the pole is the method usually resorted to for determining the latitude. But the earth not being precisely a sphere, but a spheroid, the zenith line (which is a perpendicular to the tangent plane) does not pass exactly through the centre, and the altitude of the pole is not precisely the angle subtended at the centre by the arc of the meridian. Still, however, the altitude of the pole is called the latitude of the place; and it must be distinctly understood that a latitude, astronomically determined, is the angle made by a line which is vertical at the place with its projection on the equator.

The reason why the preceding is not of more importance in the construction of maps lies in this, that when a large portion of the earth is mapped, the scale is necessarily too small to make such an error of any consequence; and when a small portion of the earth is taken, the error is nearly the same in every part of the map, and relative positions are not sensibly affected.

The determination of the longitude requires simply accurate instruments for the measurement of the positions of the heavenly bodies, and one or other of the two following—either perfectly correct watches, or perfectly accurate tables of the lunar motions. The legislature of Queen Anne, which passed an Act offering a reward for the discovery of the longitude, the problem being then very inaccurately solved for want of one or the other, good watches or lunar tables, never contemplated the invention of a method, but only of the means of making existing methods sufficiently accurate. And the legislature of George III., which repealed the former Act and substituted another, specifically limited the reward to those who should either proceed by improvement of chronometers, or of lunar tables. The rewards which were given were to Harrison for the former, and to Mayer's executors for the latter. The latter Act is now

repealed, and there does not exist any parliamentary offer of a sum of money for further improvements.

Many persons, imagining that, as in the case of the quadrature of the circle, &c., a theoretical difficulty existed, have employed themselves in endeavouring to invent a method, imagining that they should obtain the prize held out by the legislature. Some persons still occupy themselves in this manner; and it is impossible to persuade them either of the repeal of the Acts of Parliament, or of their having mistaken the nature of the difficulty, which is now, for all practical purposes, entirely conquered. It is impossible to find the latitude of a place without knowing the position of the equator in the heavens, or the longitude without knowing the meridian of Greenwich. The equator has a real existence in the heavens, since its pole is the immovable point of the heavens, which can be detected (though it is not absolutely occupied by a star) from observation of the motion of the stars, which always preserve their distance from the pole. But the meridian of Greenwich, a purely arbitrary circle of the earth, determined merely by the will of Charles II. that an observatory should be built on a certain hill near London, has no representative in the heavens. The only method, then, of finding longitude from the heavenly bodies is by finding the hour of the day which it is at Greenwich, at a particular hour on the spot whose longitude is required. It is then known how much of 360 degrees is revolved through by the earth in the period which brings a star from the meridian of the place upon the meridian of Greenwich, or *vice versa*: and this angle is the longitude. A watch which goes correctly and is set at Greenwich will carry the time at that place all over the world; or a celestial phenomenon, of which the Greenwich time may be predicted, will, if the moment of its happening be observed at any other place, give the difference of times at the moment of observation. Any proposal for finding the longitude *astronomically*, which does not depend on one or the other of these principles, is useless, unless it be that of actually measuring the distance between the given place and Greenwich, the latitudes of both being known. Whether it be possible to use any other than astronomical means for the purpose, it would be presumptuous to decide; but there certainly is no other method which offers the most distant prospect of success.

LONGLAND, or LANGELENDE, ROBERT, the reputed author of the 'Visions of Piers Plowman,' was a secular priest, born at Mortimer's Clebury in Shropshire, and afterwards fellow of Oriel College in Oxford. He lived in the reigns of Edward III. and Richard II. Longland, according to Bale, completed the 'Visions' in 1369.

LANGOBARDS, LONGOBARDI, or LANGOBARDI, *Long-beards*, a nation of ancient Germany, mentioned by Tacitus ('German,' 40) as a tribe of the Suevi. They lived east of the Elbe, towards the shores of the Baltic Sea. The Longobards joined Arminius against Maroboduus, king of the Suevi. (Tacitus 'Annal,' ii. 46.)

During the third and fourth centuries of our era the Longobards advanced to the banks of the Danube, where they became allies of Odoacer, king of Italy. Afterwards they almost exterminated the Heruli; and about the middle of the sixth century occupied

part of Pannonia, under their king Audoin. Here they came in contact with the Gepidae, a nation settled in Dacia, on the borders of the Eastern empire, and with the assistance of the Avari, totally defeated them.

In the year 568 Alboin crossed the Julian Alps, near Forum Julii, and led the Longobards to the conquest of the plains of North Italy, which have ever since been called by the name of the conquerors. [LOMBARDY.] Pavia became their capital. In 573 the nation became divided among a number of dukes, a duke of Ticino or Pavia, a duke of Friuli, a duke of Trento, a duke of Bergamo, a duke of Brescia, besides thirty dukes in as many other cities. Under these leaders the Longobards penetrated south of the Apennines, and conquered Tuscany, Liguria, Umbria, and part of Campania. The Byzantine emperors retained Ravenna, Rome, and its duchy, Padua, Genoa, Apulia, Calabria, Naples, and the southern extremity of Italy, with Sicily. After ten years of disorganization, the Longobards chose for their king Autaris, son of Clefo, 586-592, after whose death his widow Theodolinda married Agilulfus, duke of Turin, who was then raised to the throne. Agilulfus, through the persuasion of his wife, became a Catholic, most of his countrymen being Arians, and made peace with Gregory the Great, bishop of Rome. Theodolinda built the church and palace of Monza, where was deposited the iron crown (so called from a nail, said to be from the cross of our Saviour, riveted inside the crown), which was for ages employed at the coronation of the kings of Lombardy. Agilulfus died in 615, and was succeeded by his son Adaloaldus, under the regency of Theodolinda.

Rothar, son-in-law of Agilulfus, was the first king who made a compilation of the unwritten laws and usages of the Longobards, and published them in a kind of barbarous Latin, under the name of the Edict, with his own preface and observations. This edict drew a marked distinction between the Longobards and the Roman or subject population, which continued to live under the Roman law, and were looked upon as a conquered and subject race; they had neither the same political nor civil rights as the conquerors; they had no voice in their assemblies; they had no appeal against the caprice of their rulers; they lived among themselves according to Roman customs, but in any disputes between them and the Longobards were judged by Longobard judges and according to the Longobard law.

Liutprandus, who became king in 718, and reigned thirty-two years, was the most illustrious of the Longobard sovereigns. 'He was,' says Warnefrid, 'valiant in war, but fond of peace; of forgiving disposition; although destitute of learning, like most of his countrymen, yet gifted with judgment and perspicacity, and worthy of being compared with philosophers; careful of the welfare of his people, and a legislator.' Astolphus took Ravenna in 751, and put an end to the dominion of the Exarchs. [ASTOLPHUS.] Astolphus died in 756, and Desiderius, a Longobard duke, was elected his successor. Charlemagne came into Italy in 774, defeated Desiderius, and carried him prisoner into France, where he became a monk. The kingdom of the Longobards ended with Desiderius, and the Longo-

bard nation and its territories became subject to Charlemagne.

LONGTOWN. [CUMBERLAND.]

LONGUE. [MAINE-ET-LOIRE.]

LONGUS is the name of the author of a Greek pastoral romance, 'The Loves of Daphnis and Chloe,' or, according to the literal version of the Greek title, 'Pastoral Matters concerning Daphnis and Chloe,' which has been generally admired for its elegance and simplicity, and is one of the earliest specimens of that kind of composition. The author is supposed to have lived in the fourth or fifth century of our era.

LONGWY. [MOSELLE.]

LONICERA, a genus of plants, the type of the natural order *Caprifoliaceæ*. There are about sixty species of *Lonicera*, most of which have handsome flowers and emit a delicious perfume. *L. Caprifolium*, Goatsleaf, has a twining stem, with white or purplish flowers and orange-coloured berries. It is a native of the middle and south of Europe, and is found in woods and thickets in many parts of England and the south of Scotland. *L. periclymenum*, the Woodbine, or Honeysuckle, has climbing branches, flowers of a pale yellow, berries red, and accompanied with permanent bracts. This plant in early times was supposed to possess powerful medicinal properties, but it is not now used. It is, however, extensively cultivated in the gardens and shrubberies of Europe on account of the delicious perfume of its flowers. It is a native of middle Europe, and very abundant in some parts of Great Britain. *L. xylosteum*, Fly Honeysuckle, is a native of nearly the whole of Europe, in thickets, hedges, and rocky places, and by the side of woods. It is found in the same situations, but is a rare plant in Great Britain. *L. Tartarica*, the Tartarian Honeysuckle, is a native of Tartary, and is one of the most hardy of European shrubs, growing in the open air in the gardens of St. Petersburg and Stockholm. It is very common in British gardens, and is valued much on account of its early leafing and flowering.

All the species of *Lonicera* are well adapted for gardens, shrubberies, &c.

LONS-LE-SAULNIER. [JURA.]

LOO-CHOO, or LIEOU-KIEOU, or LEEU-CHEW ISLANDS, a group of islands between Japan and the Chinese island of Formosa. They lie between 24° 10' and 28° 40' N. lat., and 127° and 129° E. long., and are of different but rather small dimensions. The largest of them, called great Loo-choo, is about 65 miles by 12. The surface of these islands is mostly uneven and rugged, but the elevations do not attain a great height. They seem to be of volcanic origin. The lower tracts are of great fertility, but the most elevated are generally bare and rarely covered with wood. The fertile tracts are in high cultivation, and the produce very varied. Milk is never used; hogs, goats, and poultry, with rice and other vegetables, form the food of the inhabitants. The inhabitants are rather low in stature, but are well formed, and have an easy graceful carriage; their colour is mostly of a deep copper. Their language is similar to the Japanese. They seem to have made considerable progress in several branches of manufacturing industry, and prepare salt from sea-water in an ingenious manner. The chief products of these islands are provisions and live-stock,

with sulphur, salt, and (it is stated) copper and tin. The inhabitants manufacture cloths, paper, lacquered wares, tobacco pipes, and a liquor called *saki*. The principal foreign trade is with JAPAN, to which they are nominally subject, though they are essentially independent as regards internal administration. The government, as in China, appears to be in the hands of an aristocracy of learned men; and the king is said to be related to the imperial family of Japan. Their religion is a mixture of the doctrines and practices of Confucius, with those of Buddha. A Christian mission was established by Dr. Bettleheim, a German physician, in 1851. (Hall's *Loo-Choo*; Martin's *China*.)

LOOE, EAST and WEST. [CORNWALL.]

LOOM. [WEAVING.]

LOPE DE VEGA. [VEGA.]

LOPHIADÆ, a family of fishes of the acanthopterygious order, and forming the *Pectorales Pediculæ* of Cuvier. In this family the carpal or wrist bones are comparatively long, forming a kind of arm, at the ends of which the pectoral fins are placed. The ventral fins are in front of these. The skeleton is subcartilaginous. Under this head four genera are included, viz., *Lophius* (Cuv.), *Antennarius* (Comm.), *Malthe* (Cuv.), and *Batrachus* (Block). As a typical example of this family we may adduce the Fishing-frog, Angler, or Sea-devil, *Lophius piscatorius* (Linn.), of which an excellent account, with figures, is given in Yarrell's 'History of British Fishes,' vol. i.

LOPHIOBRANCHII, a sub-order of fishes in which the gills, instead of being pectinated, are separated into small rounded tufts, which are arranged in pairs along the branchial arches, and covered by a large operculum, so fixed as to leave only a single small orifice for the passage of the water outwards. The Pipe-fishes, *Syngnathus*, *Hippocampus*, *Solenostomus*, and *Pegasus*, are the genera included in this family.

LOPHIODON, an extinct genus of mammiferous quadrupeds, placed by Cuvier between *Palæotherium* and the *Tapirs*. M. de Blainville named the genus *Tapirotherium*.

Lophiodon differs from *Palæotherium* in the characters of the lower molar teeth, which, instead of exhibiting a continuous series of double crescents running longitudinally, are distinguished by transversal elevations, more or less oblique.

Incisors, $\frac{6}{6}$; Canines, $\frac{1-1}{1-1}$; Molars, $\frac{7-7}{6-6} = 42$.

LOPHYRUS (Gr. *λόφος*, 'a crest' and *ὄψα*, 'a tail'), a genus of Saurian reptiles, of the family *Agamidæ*, in which the head, body, and tail are surmounted by a spiny crest. The name also applies to a genus of Hymenopterous insects, of the family *Securiæ*.

LORANTHACEÆ, a natural order of Exogens, referred by most systematical writers to either the polypetalous or monopetalous sub-classes, but by others regarded as more closely in alliance with the apetalous *Santalaceæ* and *Protæacæ*. They are in nearly all cases true parasites, growing upon the branches of trees, below whose bark they insert their roots, incorporating them with the wood, and feeding upon the vital juices of the plants which they attack.

There is but one species, the common Mistletoe,

Viscum album, found wild in England. A species of *Loranthus* occurs in the south of Europe; but in the hot dry parts of tropical countries the species abound, swarming over the branches of trees, of which they often form a conspicuous feature, with their long-clustered gaily coloured flowers. As in this country the mistletoe does not injure in any considerable degree the plant which it attacks, unless it exists in unusual quantity, so in India, where *Loranthi* are common, the injury sustained by vegetation is according to the reciprocal size of the parasite and its stock.

LORANTHUS, a genus of plants, the type of the natural order *Loranthaceæ*. The species are evergreen shrubs parasitical on trees. *L. Europæus*, the European Loranthus, is an evergreen parasitical plant, and has the habit of the common mistletoe. It is a native of the southern parts of Europe, and is found on the oak, but inhabits no other tree.

LORCA. [MURCIA.]

LORD, a title given in Great Britain to peers of the realm and the archbishops and bishops, who have the right to sit in the House of Lords, as the Lords Spiritual and Temporal. By courtesy the title is also given to the eldest sons of dukes, marquises, and earls, prefixed to an inferior title of the peerage, and to the younger sons of dukes and marquises, prefixed to their Christian name and surname. The title is also bestowed on the following official personages by virtue of their offices—the Lord Lieutenant of Ireland and Lords Lieutenant of counties, the Lord Chancellor, Lord Privy Seal, Lords of the Treasury and Admiralty, the Lord High Admiral, Lord Great Chamberlain, Lord Chamberlain, Lord High Constable, Lord High Almoner, Lord High Steward, Lords in Waiting, Lords of the Bedchamber, Lords Justices, Lord Chief Baron of Exchequer, Lord Chief Justice, Lord Lyon, the Lord Mayors of London, York, and Dublin, and the Lord Provost of Edinburgh and Glasgow. The representative of the sovereign in the General Assembly of the Church of Scotland is called the Lord High Commissioner. All the judges of Great Britain and Ireland are addressed as ‘my lord,’ when presiding in court. The word is from the Saxon *hlaf*, ‘bread,’ and *ford*, ‘to give’—*hlaford*, ‘bread-giver.’

LORD ADVOCATE. [ADVOCATE, LORD.]

LORD LIEUTENANT OF A COUNTY. It was formerly used for the Crown to issue commissions of array, requiring certain experienced persons to muster and set in military order the inhabitants of the counties to which the commissioners were sent. In the sixteenth century these commissions gave place to commissions of lieutenancy, by which nearly the same powers were conferred on certain persons as standing representatives of the Crown. The right of the Crown to issue commissions of lieutenancy was denied by the Long Parliament, and formed a proximate cause of the rupture between Charles I. and his subjects. At the Restoration the right of the sovereign to issue such commissions was established by a declaratory Act, 14 Charles II. c. 3.

The Lord Lieutenant is the local representative of the Crown, the head of the magistracy, the militia, and the yeomanry; he nominates officers of militia and volunteers, and is considered responsible in cases of emergency for the preservation of the peace. His

authorities and duties with reference to military affairs are regulated by the militia acts.

The Lord Lieutenant also nominates to the Lord Chancellor all the justices of the peace for his county.

LORD OF MISRULE, the *Master of the Revels*. ‘First in the feast of Christmas,’ says Stowe (‘Survey of London,’ edition, 1603, p. 98), ‘there was in the king’s house, wheresoever he was lodged, a Lord of Misrule, or master of merry disports, and the like had ye in the house of every nobleman of honour or good worship, were he spiritual or temporal: amongst the which the mayor of London, and either of the sheriffs, had their several Lords of Misrule, ever contending, without quarrel or offence, who should make the rarest pastimes to delight the beholders. These lords, beginning their rule on Allhallow-Eve, continued the same till the morrow after the Feast of the Purification, commonly called Candlemas Day.’

LORD’S-DAY, the first day of the week, observed by Christians in commemoration of the Saviour’s resurrection, and in contradistinction to the Jewish Sabbath, or seventh day of the week, which the Mosaic law appointed for total cessation from labour. The characteristics of the Jewish Sabbath are, however, blended by many sects of believers with the features of the Lord’s-day, especially by the Scotch Presbyterians, and this rigid observance of religious duties has given rise to much wearisome and unprofitable discussion; the more latitudinarian worshippers stigmatizing their opponents as Sabbatarians, and the latter condemning the former as heterodox and profane.

It is clear from historical evidence that the Sabbath, as the Sabbath, was not recognized by the early Christians. In the days of the apostles it would seem that the faithful met on the evening of Saturday for the Lord’s Supper. Gradually the disorders which crept in at Corinth and elsewhere made a change needful. Men were enjoined to take their repast at home, so as not to profane the sacrament with the voracity of hunger. Thus, by degrees, passing as at Troas through a midnight service (Acts xx. 7), the Supper of the Lord crept on from what we should call the evening of the seventh day to the early morning of the first, and so ceased to be a supper in reality.

It is now, says Professor Plumptre, that we meet with the special adjective coined by St. Paul for the Lord’s Supper (*κυριακὸς*) applied to the day, probably by St. John in the Apocalypse (Rev. i. 10), and certainly in the writings of Tertullian and others. By a singular train of consequences, that which had originally received its holiness from one day now imparted a sanctity and a consecration to another. Henceforth the Lord’s-day was universally recognized in the Christian world as a day of joy and gladness—a day of rest, where rest was possible—for deeds of charity and Christian kindness, for devotional occupations, and for participation in that peculiar act of worship which gave the day its name. How the Lord’s-day of the Christian Church was transformed into the Sabbath of the Reformers, we shall consider in the article SABBATH. [SUNDAY TRADING.]

(On this subject the reader may consult Hessey’s *Bampton Lectures*; Professor Plumptre in *Contemporary Review*, January, 1866; *Sermons*, by Rev. F. W. Robertson; Coxe, *The Literature of the*

Sabbath Question; Ewald, *Altorthemer*; and the polemical tracts called into existence by Dr. Norman Macleod's speech on the Sabbath question before the Glasgow Presbytery, 1865.)

LORDS, HOUSE OF. [PARLIAMENT.]

LORDS JUSTICES. [JUSTICES, LORDS.]

LORDS OF REGALITY, in Scotch law, were persons to whom, on account of distinguished military services, a grant of jurisdiction was given along with their lands. [HERITABLE JURISDICTION.] In civil matters this jurisdiction was equal to that of a sheriff, and in criminal it embraced the crimes of murder and robbery. Rights of regality were abolished by the Act 20 Geo. II. c. 43.

LORDS OF THE ARTICLES, were a committee of the old Scottish Parliament, probably at first nominated by the king, but afterwards elected by Parliament itself, whose duty it was to prepare and digest all matters laid before Parliament. It was abolished in 1690, shortly after the Revolution.

LORD'S SUPPER. [COMMUNION.]

LORDSHIP. [LEET.]

LORETO. [MACERATA.]

LORETO, a department of North Peru, created in 1853. It extends from the Cordillera region of Pasco to the junction of the Amazon with the Javari, and is as large as all the other departments together. The western division is mountainous, but the eastern consists of vast well-watered plains, covered with luxuriant vegetation. The rainfall is excessive; and the mean temperature of the year 71° to 73° Fahr. The mineral products of the department comprise rock-salt, alum, sulphur, iron ore, and lignite; and gold is found in the river Napo. Steam navigation has recently been established in this region.

L'ORIENT, a seaport at the confluence of the Scorf and the Blavet, in the French department of Morbihan, is situated in 47° 44' 45" N. lat., 3° 21' 30" W. long., at a distance of 267 miles west by south from Paris, and has 35,462 inhabitants.

The town is of modern origin. It owes its importance to its having been made the naval dépôt of the French East India Company in 1666, from whence the place took its title of Port de L'Orient ('Port of the East.') At the dissolution of the company in 1720, it was made one of the stations for the French navy, and a free commercial port. The town is fortified; the houses are well-built; the streets wide, clean, and well-paved, and there are several pleasant promenades. The port is on the east side of the town, from which it is walled of: its length is nearly 4000 feet; its breadth is nearly 2000 feet. The royal dockyard is one of the finest in the kingdom; there are slips for laying down thirty vessels of war at a time. The harbour is bordered by fine quays, on which are large buildings connected with the dockyard, and an observatory. There is a signal-tower 123 feet high, built on an eminence south of the harbour, from which vessels can be discerned 30 miles out at sea. L'Orient has manufactures of hats, linens, braid, gold lace, and pottery; the exports consist of corn, wine, brandy, iron, lead, cotton and woollen stuffs, hardware, &c., cattle, and manufactured goods. The sardine and pilchard fishery is actively carried on.

L'Orient is the seat of a maritime prefect; it has

also a chamber of commerce, an exchange, national and communal college, town-hall, theatre, and a public library.

LORIMER, (bridle-cutter, from Lat. *lorum*, 'a thong'), is the name given to the persons employed in those trades which supply the metal fittings for saddles and harness generally. They have a guild in London, and in the Scotch burghs are comprehended as a branch of the corporation of hammermen. In the latter country, however, the term is also applied to cutlers, locksmiths, and brass founders.

LORIOL. [DRÔME.]

LORIS, a genus of *Nycticebidae*, a family of Quadrumana which links the Bats with the true Monkeys. The Loris are noted for their small ears, round head, and want of tail. They are natives of India and the islands of the Indian Archipelago. By some the generic name *Stenopis* is applied to them, by others they are set down as lemurs (*Lemuridae*); but as the true lemurs are all natives of Madagascar, it is better to associate the Indian forms with the family name given above. The Loris are nocturnal animals, seldom venturing abroad during the day. They live on fruit; their fur is much prized.

LORNE. [ARGYLESIRE.]

LOROUX. [LOIRE INFÉRIEURE.]

LORRAINE, a large province of France, which now forms the departments of VOSGES, MEURTHE, MOSELLE, and MEUSE. After having formed part of Gallia Belgica under the Romans, and of Austrasia under the successors of Clovis, the territory of Lorraine was united to the empire of Charlemagne. It was afterwards erected into a duchy, and in course of time passed to the house of Austria. By the treaty of Vienna, concluded November 18, 1736, Francis Stephen, duke of Lorraine and husband of Maria Theresa, exchanged for the duchy of Tuscany the duchies of Lorraine and Bar, which were ceded to Stanislas Leczinski, the father-in-law of Louis XV., during his life. Stanislas having died on the 3rd of February, 1766, the two duchies were reunited to France.

Lorraine included the duchy of Lorraine, the duchy of Bar, and the Pays-des-Trois-Évêchés, which had Nancy, Bar-le-Duc, and Metz, for their respective capitals.

LORRAINE, CARDINAL DE. [GUISE.]

LORRAINE, CLAUDE, a celebrated Italian artist, whose real name was Claude Gelée, was born in Lorraine, near Charnes, in 1600. Owing to the poverty of his parents he was brought up as a cook, and in that capacity went to Rome, where he was engaged as his servant and factotum by Agostino Tassi, the landscape painter. Here he had numerous opportunities of studying the mechanism of the pictorial art, and employed them to such advantage that he was soon able to abandon his menial duties. He became distinguished for his landscapes, which exhibit a wonderful fidelity to nature, and owing to the painter's exquisite management of light, produce a powerful impression on the spectator's fancy. In England his works have always been very popular, though Turner, if no other of our native artists, has shown that even in his own peculiar line of art he is by no means unapproachable. Prosperous and contented, absorbed in the study of nature, and happy in the cultivation of his remarkable genius, Claude

lived to a ripe old age. He died at Rome on the 23rd of November, 1682, in his eighty-third year.

LORY. [PSITTACIDÆ.]

LOSTWITHIEL. [CORNWALL.]

LOT, a department in France, formed of part of the old province of Guienne, between the departments of Cordeze, Dordogne, Lot-et-Garonne, Tarn-et-Garonne, Aveyron, and Cantal. Its greatest length from north-east to south-west is 65 miles, and its average breadth is 35 miles. The area is 2012 square miles, and the population 295,542.

Hydrography.—The department takes its name from the *Lot* (anc. *Oltis*), which, rising in the mountains of Lozère, flows in a general western direction across the departments of Lozère, Aveyron, Lot, and Lot-et-Garonne, where it enters the Garonne on the right bank a little above Aiguillon, after a course of 270 miles, 187 of which, from Entraignes, where it is joined by the Truyère, in the department of Aveyron, are navigable. The north of the department is drained by the DORDOGNE. The watershed between these two rivers is formed by a prolongation of the Auvergne mountains, which traverse the department from north-east to west, dividing it into two slopes, the northern one belonging to the basin of the Dordogne, the southern one to the basin of the Garonne. The *Selle*, which flows along the south-eastern side of this mountain range, and enters the Lot on the right bank near St. Cirq, is the only other river of importance. Some small feeders of the Garonne rise in the south of the department, the largest of which is the Barguelonne. The eastern districts of the department are covered with low hills which are ramifications of the Cévennes.

Soil and Products.—The deep soils of the valleys and plains yield fine crops of wheat, maize, barley, and oats; on the lighter soils, rye, rape, and buckwheat are grown; and on the strongest soils considerable quantities of hemp and tobacco are raised. The hill-slopes along the rivers are generally laid out in vineyards, which yield annually 13,200,000 gallons of wine, the best kinds being those of Cahors and Grand-Constant. About two-thirds of the whole produced is exported or distilled into brandy. The white mulberry is extensively cultivated for the production of silk. Excellent truffles are found. Plums are grown in large quantities, and, when dried, form an important article of export. Turkeys, geese, game, and poultry generally, are very plentiful. Horses, cows, and sheep are of inferior breeds; goats are numerous; and large numbers of pigs are fatted for the supply of the neighbouring departments. Wild boars are now rarely met with. Hares and rabbits are very numerous, and of large size. Fish is abundant in all the rivers, among which the Cère, a feeder of the Dordogne, is famous for eels, and the Lot for carp of enormous size.

Some iron and coal mines are worked; lead, calamine, marble, millstone-grit, granite, limestone, potter's and fuller's earth, &c., are found.

The manufactures of the department are unimportant; there are a few iron forges, potteries, and paper-mills, and numerous corn and flax mills.

Climate.—The department presents great differences of temperature and climate. Among the granitic highlands of the east, the winters are long and rude, generally lasting from November to April,

during which time snow and rain, each accompanied by cold winds, alternately succeed each other. The calcareous slopes of the Auvergne range have a drier and less rigorous climate, and a much shorter winter. In the plains and the valleys of Dordogne and the Lot, the climate is genial, except during the spring, when the night frosts are often very harsh and biting.

Divisions, Chief Towns, &c.—The area of the department is 948,062 English acres. It is divided into three arrondissements, which, with their subdivisions and population, are as follows:—

Arronds.	Cantons.	Communes.	Pop.in1863.
Cahors, . . .	12	129	118,151
Figeac, . . .	8	112	94,171
Gourdon, . . .	9	74	83,220
Total, . . .	29	315	295,542

Of the arrondissement of Cahors, and of the whole department, CAHORS is the capital. *Castelnau-de-Montratier* occupies the summit of a steep hill, 12½ miles S. from Cahors, and has 1015 inhabitants. Its position, its ramparts and strong castle, of which there are still some vestiges, rendered it formerly a town of considerable importance. *Montcuq*, situated on a conical hill between two valleys, 14 miles S.W. from Cahors, has 2321 inhabitants. *Puy-l'Evêque* is situated on a peninsula formed by the Lot, on its right bank, 15 miles W. by N. from Cahors, and has 2321 inhabitants.

In the arrondissement of Figeac, the chief town, *Figeac*, is situated in a pretty valley surrounded by hills, which are covered with woods, vineyards, and orchards, on the right bank of the *Selle*, 32 miles N.E. from Cahors, and has a tribunal of first instance, a college, and 8381 inhabitants. Manufactures of cotton and linen are carried on; there are also dye-works and tanneries. Two obelisks, called *Aiguilles*, one S., the other W. of the town, are remarkable for their structure and antiquity; they were used in former times as fire-beacons to guide travellers by night through the surrounding countries, which were then covered with dense forests. *Cajarc*, a town of 1928 inhabitants, is situated in a very fertile district, on the right bank of the Lot, 12 miles S.W. from Figeac. *St. Céré*, 18 miles N. by W. from Figeac, is built on an island formed by the Bave, a feeder of the Dordogne, and has 4302 inhabitants, who manufacture great quantities of hats, and trade in linens. To the north of the town are the remains of a fortified camp, said to be Roman, in which, however, several ecclesiastical structures seem to have been erected; of these, two lofty isolated towers are still standing.

The arrondissement of Gourdon takes its name from its chief town, *Gourdon*, which is situated on a hill in the west of the department, 22 miles N. from Figeac, and has a tribunal of first instance, a college, and 5099 inhabitants, who manufacture woollen stuffs, and trade in wine and truffles. The town, which is tolerably well built, and has a handsome church, was formerly surrounded by strong ramparts. *Gramat*, situated in a romantic valley, 16 miles N.E. from Gourdon, on the right bank of the Alzon, a feeder of the Dordogne, has saline baths and springs, and 4074 inhabitants. *Martel*, 11 miles N. by W.

from Gramat, has a college and 3098 inhabitants. It owes its origin and name to Charles Martel, who erected a church here which was rebuilt on a large scale in the year 1300, and is lighted through stained-glass windows remarkable for beauty of colouring and correctness of design; the subjects represented are the principal incidents of our Saviour's passion. *Souillac*, a well-built town, with a tribunal of commerce and 3128 inhabitants, is situated in a fertile valley, 12 miles N. by E. from Gourdon, on the right bank of the Dordogne, which is here spanned by a stone bridge of seven arches. Coarse woollens, agricultural implements, bar iron, leather, and iron-ware are manufactured; there is also some trade in wine, tobacco, hides, salt, groceries, oak-staves, cattle, &c.

The department forms the see of the bishop of Cahors; it is included in the jurisdiction of the Cour Imperiale of Agen and of the University Academy of Toulouse, and belongs to the twelfth Military Division, of which Toulouse is head-quarters. It returns two members to the Chamber of Deputies.

(Malte Brun, *Géographie Universelle; Statistique de la France; Annuaire pour l'An 1866.*)

LOT-ET-GARONNE, a department in France, comprising the former district of Agénois, part of the diocese of Condom, and portions of those of Bazas, Lectoure, and Cahors, takes its name from the Lot and the Garonne, which traverse it, the former from N.E. to W., the latter from S.E. to N.W., and is bounded N. by the department of Dordogne, E. by those of Lot and Tarn-et-Garonne, S. by that of Gers, and W. by those of Landes and Gironde. Its greatest length from N.E. to S.W. is 63 miles, from S.E. to N.W. 55 miles. The area is 2048 square miles, and the population 332,065.

Surface and Products.—The surface of the department presents a high plain, furrowed to different depths by river-valleys, but diversified in the south by some low swells, the last declivities of the Pyrenees northwards; the whole inclining towards the north-west and belonging to the basin of the Garonne. Nothing can exceed the beauty and fertility of the valleys of the Lot and the Garonne; the slopes that inclose them are covered with vines and other fruit trees, especially the fig and the plum, and the low lands yield abundantly wheat, maize, rye, hemp, tobacco, &c. The valley of the Baise, in the south, and that of the Dropt, in the north of the department, are also very fertile. With these exceptions, the department presents an arid, treeless surface, with a barren stony soil, especially in the eastern districts at a little distance from the Lot and the Garonne. In the upper part of Agénois, the soil is a stiff iron-coloured clay that ill repays the labour of the husbandman; and in the Landes, which extend over the south-west of the department along the Avenne, the ground is covered with arid sands, unhealthy marshes, and in some places with a scanty soil, which can with difficulty be made to produce a few ears of corn. In this last district there are also some hungry pastures and forests of pine and cork; the cork woods along the left bank of the Gelise, a feeder of the Losse, in the south of the department, are the largest in France. On the northern borders there are fine chestnut woods. The quantity of wine annually produced is 15,000,000 gallons, half of which is retained for home consumption; part of the

surplus is distilled into brandy, and the remainder is exported to Bordeaux. Cattle, horses, mules, and sheep are reared in immense numbers, and geese form an important article of export. Game and freshwater fish are plentiful. The climate of the department is in general very healthy; but long alternations of drought and rain are not uncommon.

The principal rivers are the Lot, the GARONNE, the Baise [GERS], the GERS, and the Dropt [DORDOGNE].

Natural Products, &c.—Iron mines are worked; good building stone, calcareous spar, gypsum, and marl are found. The chief manufactures are cork (for which there is a national establishment), vinegar, sailcloth, linen, swanskins, pottery, linen and cotton yarn, gloves, calico, iron, glass, paper, lime, ropes, leather, tobacco. The commerce is composed of the various industrial and agricultural articles enumerated, and of pitch and tar made from the pines of the Landes.

Divisions, Chief Towns, &c.—The area of the department is 1,320,531 acres. It is divided into four arrondissements, which, with their subdivisions and population, are as follows:—

Arronds.	Cantons.	Communes.	Pop. in 1863.
Agen, . . .	9	72	80,517
Marmande, .	9	98	99,389
Villeneuve-d'Agen, . .	10	84	92,241
Nérac, . . .	7	62	59,918
Total, . .	35	316	332,065

In the arrondissement of Agen, the chief town, Agen, which is also the capital of the department, and of the former district of Agénois, is situated in a wide and rich plain, on the right bank of the Garonne, in 44° 12' 27" N. lat., 0° 37' 50" E. long., at a distance of 88 miles S.E. from Bordeaux, 377 S. from Paris, and has 17,263 inhabitants. The town, which existed under the name of *Aginum* in Roman times, is ill built. The finest quarter is the suburb on the Bordeaux road, which runs along the right bank of the river, and terminates in the magnificent promenade of Gravier. This promenade, which communicates with the left bank of the Garonne, by a fine suspension bridge at one end, and by a stone bridge of eleven arches at the other, consists of an avenue formed by gigantic elms, that interlace their boughs high overhead, forming a continuous vault of living verdure, all but impenetrable to the rays of the sun; while on either hand their trunks and side branches are fashioned into elegant arcades. The principal buildings in Agen are—the cathedral church of St.-Caprais; the church of the Jacobins, the former episcopal palace, now the residence of the prefect; the ecclesiastical college; and the public library, which contains 15,000 volumes. From a rocky height near the town, called l'Hermilage, there is a magnificent view over the rich valley of the Garonne, with the Pyrenees in the distance. In a recess on its picturesque slope is shown the house of the Scaligers, the younger of whom was born here. It was also the birthplace of Palissy, the potter, and Lacépède, the naturalist. Agen gives title to

a bishop; it is the seat of the Cour Impériale for the departments of Lot, Lot-et-Garonne, and Gers, and has tribunals of first instance and of commerce, a normal school, two schools for the education of the clergy, and a communal college. The town is surrounded with plum orchards, which supply Europe with their dried produce, under the well-known name of prunes. The manufactures consist of sailcloth, starch, linen, serge, swanskins, printed cottons, brandy, leather, &c.; the commerce in corn, flour, wine, brandy, plums, woollen cloth, cotton yarn, feathers, &c., is considerable. Steam-boats ply regularly between Agen and Bordeaux. *Astafort*, on the right bank of the Gers, 10 miles S. from Agen, is said to have been built by the English and named *Stafford*. It is surrounded by old turreted half-ruined walls, and has 2434 inhabitants. A large cross marks the spot, still called *Champ des Huguenots*, on which the prince de Condé was defeated in the religious wars. *Port-Sainte-Marie*, 12 miles W. from Agen, is built at the foot of a high hill, on the right bank of the Garonne, which is here crossed by a fine suspension bridge and forms a commodious harbour for river craft. The high road to Bordeaux passes under an arcade surmounted by a lofty tower, the whole built with small square stones, and supposed to be of Roman erection. The population of the town is 2856.

In the arrondissement of Marmande, the chief town, *Marmande*, is situated in the west of the department, on a hill above the Garonne, which is here crossed by a bridge of a single arch. The town has an old-fashioned look; many of the houses are timber-framed. The most important buildings are the town-hall, the court-house, the college, and the hospital. Marmande is the seat of a tribunal of first instance, and has 8661 inhabitants, who manufacture hats, woollen stuffs, brandy, ropes, and leather. It has also a considerable trade in corn, flour, wine, brandy, plums, hemp, tobacco, &c. Steam-boats ply several times a day to Bordeaux. *Clairac*, a clean well-built town, stands in a pretty situation on the right bank of the Lot, has 2313 inhabitants, who trade in white wine, plums, flour, tobacco, &c. *Castel-Moron*, formerly a fortified town, which was held more than a century by the English, stands on the Lot, and has 2094 inhabitants. *Le-Mas-d'Agénois*, a small but ancient town, stands 8 miles from Marmande, on the left bank of the Garonne, and has 2153 inhabitants. *Tonneins*, a few miles E. of Le-Mas-d'Agénois, on the right bank of the Garonne, which is here spanned by a suspension bridge, and on the railway from Bordeaux to Cette, is a cheerful, well built town, situated on the sides of a hill, from whence there is a delightful view. The town-hall, the theatre, and the public baths are the most conspicuous buildings. Tonneins has a population of 7947, who manufacture great quantities of ropes, leather, and tobacco, and trade in these articles, as also in hemp, plums, wine, corn, and brandy, &c. There is a national tobacco factory here. Tonneins was the birthplace of Madame Cottin.

The arrondissement of Villeneuve-d'Agen takes its name from *Villeneuve*, a town of 13,830 inhabitants, 14 miles N. from Agen, situated on the Lot, which divides it into two unequal parts, united by an ancient bridge of remarkable structure. The greater

part of the town is on the north bank of the river, and consists of several wide, straight, well-built streets, that abut in a circus surrounded by arcades. Of the old fortifications, two towers and the castle still remain; the ramparts have been turned into handsome promenades. The buildings of the ancient abbey of Eysse, situated about $\frac{3}{4}$ of a mile N. of the town, now form a convict prison. Villeneuve has tribunals of commerce, and a college. Linen, leather, tiles, hammers for metal foundries, &c., are manufactured; the commerce is composed of flour, plums, wine, cattle, paper, iron, copper, &c. *Fumel*, E. by N. from Villeneuve, on the right bank of the Lot, has paper mills, and 3000 inhabitants. *Sainte-Livrade*, W. of Villeneuve, and near the left bank of the Lot, has a population of 3018, who manufacture leather, and trade largely in plums. *Monflanquin*, situated on a hill, near the left bank of the Lède, 9 miles N. from Villeneuve, had, in 1861, 3842 inhabitants. The streets are narrow, steep, and ill-paved. The neighbourhood is fertile in wine and fruits. *Tournon*, a market town, 16 miles E. from Villeneuve, situated on a hill on the right bank of the Baudusson, a feeder of the Lot, has 4569 inhabitants.

The arrondissement of Nérac comprises the southwest of the department, and takes its name from the chief town, *Nérac*, which is prettily situated on the Baise, 15 miles S.W. from Agen, and has tribunals of first instance and of commerce, a college, and 7283 inhabitants, who manufacture coarse linens and woollens, sea biscuits, corks, leather, and great quantities of flour. The old town, situated on a steep slope on the right bank of the Baise, is ill built, with narrow streets of old wooden houses; it is joined by two stone bridges to the new town, which stands on the left bank, and is larger and better built. This town has several pretty and shady walks, one of which is adorned with a statue of Henri IV. The mosaics, the remains of a palace, a temple, an aqueduct, and of baths, found here, mark the place as the site of a Roman city, the name of which is lost. The town trades in linen, hemp, flax, wine, brandy, &c., and is famous for its partridge patties. Nérac has an important corn market. *Castel-Jaloux*, 18 miles N.W. from Nérac, on the left bank of the Avance, is a pretty and well built town, not far from the commencement of the *Landes*, and has 2852 inhabitants, who manufacture coarse cloth, paper, glass, leather, &c. It has also iron forges, copper foundries, smelting furnaces, hydraulic saw mills, and a considerable trade in corn, wine, pitch, and tar, oak-bark, chestnuts, and leeches. *Mézin*, 7 miles S. from Nérac, on the right bank of the Gelise, a feeder of the Baise, is an ill built town, with 2992 inhabitants, who manufacture corks, pottery, flour, paper, and leather.

The department forms the see of the bishop of Agen, is included in the jurisdiction of the Cour Impériale of Agen, and of the Academy of Bordeaux, and belongs to the fourteenth Military Division, of which Bordeaux is head-quarters. It returns three members to the Chamber of Deputies. (*Dictionnaire de la France; Annuaire pour l'An 1866.*)

LOTHIANS, a term under which that part of Scotland is comprehended which stretches along the southern shores of the Frith of Forth, and includes the three counties of Haddington, Edinburgh, and

Linlithgow. The first of these counties is also called East Lothian, the second Mid Lothian, and the last West Lothian. This region lies between $56^{\circ} 40'$ and $56^{\circ} 5' N.$ lat., and between $2^{\circ} 24'$ and $3^{\circ} 50'$ W. long. The soil is usually fertile and repays cultivation. The Lothians were taken possession of by the Saxons in 450, and were not incorporated with the rest of Scotland until the close of the eleventh century.

LOTIONS, or washes, termed also epithems, and when intended for the eye, collyria, or eye-washes, are either mixtures of different ingredients, or solutions of various medicinal substances, in water or other menstrua, designed for external application. Many of the nostrums sold under the name of lotions are solutions of very active ingredients, and their application is often productive of very serious effects.

LOTTERIES have been encouraged by some states for the purpose of raising a revenue. The general plan has been for the government to sell a certain number of tickets or chances, and to distribute by lot a part of the money thus collected among a comparatively small number of the purchasers. Lotteries are games of chance, the aggregate number of players in which are sure to lose a part of their venture.

The earliest English lottery of which there is any record was in 1569, when 40,000 chances were sold at ten shillings each; the prizes consisted of articles of plate, and the profit was employed for the repair of certain harbours. In the course of the following century the spirit of gambling appears to have been materially increased in this direction, for *private* lotteries were early in the reign of Queen Anne suppressed 'as public nuisances.' In 1823, the last Act that was sanctioned by Parliament for the sale of lottery tickets, contained provisions for putting down all private lotteries, and for rendering illegal the sale in this kingdom of all tickets, or shares of tickets, in any foreign lottery, which latter provision is evaded to this day. On the ground of injury to public morals lotteries of all kinds were abolished in England in 1826. In Scotland lotteries have been declared illegal by a long series of statutes, commencing with the 10 & 11 Will. III. c. 17.

The system of state lotteries was very long carried on by the French government, and was the cause of still greater demoralization than in England. State lotteries were abolished in France in 1836, and in Hesse-Darmstadt in 1852, but many German states still countenance and derive a portion of their revenue from them. Experience has, however, proved that it is one of the very worst methods that could be adopted for adding to the revenue of any country.

Lotteries have been very common in the United States, and have been sanctioned by the several states, not so much as a means of raising money for state purposes, as with the view of encouraging, as they supposed, many useful objects which could only be effected by raising at once a large sum of money, such as canals, the establishment of schools, and even the publication of a book. The numerous frauds practised in lottery schemes in the United States have perhaps done more to open the eyes of the people to the mischief resulting from them than any investigation into the true principles of lotteries. The 9 & 10 Vict. c. 48, legalizes art-unions in this country. [ART-UNIONS.]

LOTTO, LORENZO, is supposed to have been one of the scholars of the Bellini, and also an imitator of Leonardo da Vinci. He lived long at Bergamo, and was generally considered a native of that place. He died at Loretto. His works range from 1513 to 1554.

LOTUS. The plants referred to by classical authors under the name of *Lotos* or *Lotus* are very numerous. No less than eleven have been enumerated. Of these some are herbaceous, others perennial. Among the former are the *Lotus sativa* and *L. sylvestris* of Dioscorides; the first is also called *trifolium*; it is supposed by some botanists to be *Melilotus officinalis*, and by others to be *M. cærulea*. Dr. Sibthorp has fixed upon *Melilotus messanensis* as the plant.

The *Lotus sylvestris* of Dioscorides, called also *Libyon*, a native of Libya, and about two feet high, with leaves like those of *Lotus trifolium*, and fruit like that of Fennugreek, is thought to be the *Trigonella elatior* of Sibthorp, which he found in Asia Minor and in Cyprus.

Lotus Ægyptia, or the Egyptian Lotus, is no doubt one of the *Nymphæaceæ*, being described as springing up in Egypt in fields inundated by the river, with a stem like that of the *νύμφες*, or Egyptian Bean (*Nelumbium speciosum*), and a white lilaceous flower, which rises out of the water at sunrise, and sinks down again at its setting, a capsule like that of the poppy, in which are contained seeds which the Egyptians roast and make into bread, with a root which is likewise eaten, both in a dressed and undressed state. The plant is no doubt the *Nymphæa Lotus* of botanists. But as in the most ancient monuments a blue-coloured lotus is likewise represented, there is no doubt that the Egyptians were also acquainted with the *Nymphæa cærulea*.

The Egyptian lotus, however, is not so celebrated as another less known tree, to which exaggerated description has assigned a fruit of the most delicious kind, upon which the Lotophagi lived, and which when strangers had once tasted, they ceased to wish to return to their native country: a legend that has suggested Tennyson's beautiful poem of 'The Lotus-Eaters,' and is given in full in the ninth book of the 'Odyssey.' This is specially described as a tree, but there is no doubt that several have been confounded under this name. One has been described by both Dioscorides and Pliny. Polybius also describes another as the African Lotus. The true lotus of the ancients, however, would seem to have been the *Nitraria tridentata*. Dr. Shaw, in his 'Travels in Barbary,' figures a species of *Zizyphus* which he calls 'Sedra Arabum, quæ et Lotus veterum.' It is a prickly branching shrub, with fruit of the size of a wild plum, and of a sweetish taste and saffron colour. He found it sold in the markets, cattle fed with it, and a liquor drawn from it. Desfontaines also found this *Zizyphus Lotus* on the same coast, and has fully described it. Mungo Park found a species of *Zizyphus* in the interior of Africa, which forms a large tree with yellow farinaceous berries of a delicious taste. The natives, he says, convert them into a sort of bread, by exposing them some days to the sun, and afterwards pounding them gently in a mortar, until the farinaceous part is separated from the stone. This meal is then mixed with a little water, and formed into cakes, which, when dried in

the sun, resemble the sweetest gingerbread. The Arabs call it *Nabk* or *Nabka*. It may be added that the fruit of several species of *Zizyphus* is eaten in India.

LOUDEAC. [CÔTES-DU-NORD.]

LOUDON, JOHN CLAUDIUS, was born at Cambuslang, in Lanarkshire, on the 8th of April, 1783. As a child he exhibited a taste for gardening, and at the age of fourteen he was placed with a nurseryman and landscape gardener. During this period he acquired the habit of sitting up two nights every week for the purpose of study, which he continued for many years.

In the year 1803 Loudon first came to London, and became a landscape gardener. One of his earliest literary efforts was a paper contributed to the *Literary Journal* entitled 'Observations on laying out the Public Squares of London.' In 1804 he published his first work, entitled 'Observations on the Formation and management of useful and ornamental Plantations.' In 1805 he published 'A short Treatise on some Improvements lately made in Hothouses;' in 1806, a 'Treatise on forming, improving, and managing Country Residences, and on the choice of situations appropriate to every class of purchasers.' In 1822 appeared his great work, 'The Encyclopædia of Gardening.' A second edition was published in 1824. Its success led him to engage in the 'Encyclopædia of Agriculture,' published in 1825. Another work was edited by him, and published in 1829, with the title 'Encyclopædia of Plants.' This was followed by the 'Encyclopædia of Cottage, Farm, and Villa Architecture,' published in 1832. 'The labour,' says Mrs. Loudon, 'that attended this work was immense; and for several months he and I used to sit up the greater part of every night, never having more than four hours' sleep, and drinking strong coffee to keep ourselves awake.' He then planned his 'Arboretum et Fruticetum Britannicum,' brought out in 1838. An attack of rheumatic fever in 1806 was so severe as to produce permanent anchylosis of his left knee. Subsequently his right arm became affected, and was amputated in 1826. In the meantime his left hand became affected, so that he could only use the third and little finger. After this period he was obliged to employ for all his works an amanuensis and a draughtsman. Early in 1843 he was attacked with chronic inflammation in the lungs, which terminated his existence on the 14th of December of that year. He continued working till the day of his death, and 'died standing on his feet.'

LOUDUN. [VIENNE.]

LOUGH, an Irish term synonymous with the Scotch *loch*, but not with the English *lake*, for 'loch' and 'lough' are applied to designate arms of the sea as well as collections of fresh water, which the word 'lake' is not.

LOUGHBOROUGH. [LEICESTERSHIRE.]

LOUGHREA. [GALWAY.]

LOUHANS. [SAONE-ET-LOIRE.]

LOUIS I., called 'le Débonnaire,' and also 'the Pious,' son of Charlemagne, was made his father's colleague in the empire in 813, and after the death of Charlemagne in the following year, succeeded him as King of France and Emperor of the West. Bernard, son of Pepin, elder brother of Louis, having conspired to supplant his uncle in the empire, was

seized by order of Louis, and his eyes were put out, in consequence of which he died in a few days. Louis showed great sorrow for this act of cruelty, to which he had been advised by his courtiers, and did public penance for it before an assembly of bishops. In 820 he appointed his son Lotharius king of Italy and his colleague in the empire. To his son Louis he gave Bavaria, Bohemia, and Carinthia, and to his other son Pepin, Aquitania. The whole of his reign was a series of revolts and contentions between him and his sons, partly caused by the conduct of the Empress Judith of Bavaria, a licentious and ambitious woman. In the midst of these troubles he died in June, 840. Lotharius was acknowledged emperor, and after a war against his brothers retained Italy, Provence, Burgundy, and Lorraine. Charles the Bald succeeded his father as King of France, and Louis of Bavaria had all Germany.

LOUIS VI., called 'le Gros,' son of Philip I., succeeded his father in 1108. The larger part of the kingdom was then in the hands of the great vassals of the Crown, over whom the king's supremacy was but nominal. The duchy of Normandy was in the possession of Henry I. of England. Henry and Louis quarrelled about the limits of their respective states, and thus began the wars between the English and the French in France which lasted for more than three centuries. Louis had the worst in several encounters.

Assisted by his minister, l'Abbé Suger, Louis succeeded in recovering for the Crown some of the power which the great vassals had usurped, and he began the creation of the third estate, or commons, as a check on their power. He died at Paris, in 1137, aged sixty, and was succeeded by his son Louis VII.

LOUIS IX., called St. Louis, succeeded his father Louis VIII. in 1226, when he was twelve years of age, under the regency of his mother Blanche of Castile. During his minority, a constant struggle prevailed between the Crown and the great feudatories, in which the latter eventually triumphed. Louis then (1248) set out on a crusade to the Holy Land. He landed in Egypt, and took Damietta, but being defeated at the battle of Mansoura, he was taken prisoner, compelled to pay a heavy ransom, and to restore his captures to the Mussulmans. From Egypt he sailed to Acre, and carried on the war in Palestine, but with no success, till the year 1254, when he returned to France. He curbed the power of the nobles; published several useful statutes, known by the title of 'Etablissements de St. Louis;' established a police at Paris; classed the various trades into companies called confraries; established the college of theology called La Sorbonne; created a French navy, and made an advantageous treaty with the king of Arragon, by which the respective limits and jurisdictions of the two states were defined. The chief and almost the only fault of Louis, which was that of his age, was his religious intolerance. A feeling of fanaticism led him to another crusade, in which he met his death. He sailed for Africa, laid siege to Tunis, and died in his camp of the plague on August 25, 1270. Pope Boniface VIII. canonized him in 1297. Louis' brother Charles, count of Anjou and Provence, took the kingdom of Naples from Manfred of Suabia, and established there the dynasty of Anjou. [ANJOU.]

LOUIS XIII., son of Henri IV. and of Mary de' Medici, succeeded his father in 1610, being only nine years of age, under the regency of his mother. In October, 1614, he was declared to be of age, and in the following year he married Anne, daughter of Philip III. of Spain. Concino Concini, *maréchal d'Ancre*, a Florentine, the favourite minister of the queen-dowager, had by his insolence and his intrigues excited considerable jealousy, and was killed at the instigation of the king. The Parliament of Paris declared him to have been guilty of treason and sorcery; and on the same charges his wife was afterwards beheaded and her body burnt. The queen-dowager was sent to Blois under arrest. De Luynes, a young courtier, now became the ruling favourite; for Louis was totally incapable of governing himself during the whole of his life. Some years after the queen-dowager escaped from Blois, and being supported by several nobles a civil war broke out; but Armand du Plessis, bishop of Luçon, known afterwards as Cardinal and Duke de Richelieu, acted as mediator, in consequence of which he obtained a cardinal's hat, in 1624 (on the death of De Luynes) became chief prime minister, which he continued to be till his death in 1642. He checked the ambition of the House of Austria, and acquired for France considerable influence in the affairs of the empire. In 1628 Richelieu captured La Rochelle, the great stronghold of the Protestants of France. The French armies took an important and generally a successful part in the Thirty Years' War; they acted on the Rhine in concert with the Swedes, and whilst another French army carried on the war in Italy against the Spaniards, a third army was fighting in Flanders, and a fourth on the frontiers of Catalonia. The great object of Richelieu was to render the government of the king absolute, and he succeeded. He at the same time patronized learning and the fine arts, established the royal press, and embellished Paris. Louis died in May, 1643.

LOUIS XIV. was born at St. Germain-en-Laye, September 16, 1638, and succeeded his father when hardly five years old. Cardinal Mazarin was the minister, under the regency of the queen-mother. The treaties of Münster and Osnabrück (1648) put an end to the Thirty Years' War, and Mazarin concluded the peace of Westphalia. The same year, however, that the war in Germany was terminated, the civil war of La Fronde broke out in France. [FRONDE.] This war lasted with some intermissions till 1652, when Condé, one of the chief leaders of the Frondeurs, emigrated to join the Spaniards, and Cardinal de Retz, another of their supporters, was imprisoned. During the continuance of the war the court were twice obliged to leave Paris, and the consequence of a temporary reconciliation was the disgrace and exile of Mazarin in 1651, who, however, returned and resumed his ministry in 1653. In 1654 Louis XIV. made his first campaign in Flanders against the Spaniards. In the following year he concluded a treaty of alliance with Cromwell against Spain. The war continued that and the next year with various success; Turenne commanded the French troops, and the prince of Condé fought on the side of the Spaniards against his own country.

In 1657 the Emperor Ferdinand III. died, and Mazarin intrigued, by means of bribery and promises,

to prevent the election of his son Leopold, and to obtain the imperial dignity for Louis XIV. But he was unsuccessful: even those who had received his pay turned in favour of Leopold, who was unanimously elected in 1658. From that time began the bitter animosity of Louis against Leopold, which lasted half a century, and was the cause of three long and bloody wars.

Meantime the war with Spain was brought to a close in November, 1659, by Cardinal Mazarin, by the treaty of the Bidassoa, in which the marriage between the Infanta Maria Theresa, daughter of Philip IV. of Spain, and Louis XIV. was concluded. Spain gave up Artois and Roussillon, and stipulated for a free pardon to the prince of Condé.

The new queen was weak in her intellect, but harmless and good-natured. Louis XIV. always behaved to her with considerate regard, but never felt any affection towards her; and he resorted to the society of a succession of mistresses, of whom Mademoiselle de la Vallière, Madame de Montespan, and Madame de Maintenon are the best known. In February, 1661, Mazarin concluded at Vincennes a third and last treaty with Charles, duke of Lorraine, by which Strasbourg, Pfalsburg, Stenai, and other places were given up to France. Nine days after this treaty Mazarin expired, at fifty-nine years of age.

On the death of Mazarin Louis XIV. took the reins of government entirely into his own hands. He banished and imprisoned Fouquet, the minister of finance, on charges of peculation and treason. In appointing Colbert in his room, Louis made a good choice, and much of the splendour of his reign is due to that able minister. [COLBERT.]

Louis XIV. completed the work begun by Richelieu; he changed France from a feudal monarchy into an absolute one. After the death of Mazarin he admitted no more ecclesiastics into his council. The spirit of jealousy of the Gallican Church made it less dependent on Rome, and more subservient to the Crown. The parliaments were also subdued, like the nobility and clergy, by the absolute will of Louis, and offered little or no impediment to the royal authority. 'L'état c'est moi,' his famous saying, explains the whole principle of his policy. He established that system of centralization in the administration which has been followed and rendered more complete by succeeding governments, and which has rendered France the most compact power in Europe. His reign was a brilliant epoch of learning in France. In his patronage of the arts he displayed more pomp than taste.

Louis XIV. hated the Protestants, not so much from religious bigotry as because he considered them as rebellious subjects. This led him to that most unjust and disastrous measure, the revocation of the Edict of Nantes in 1685, by which Protestantism was proscribed in France, and by which that country lost thousands of its most industrious citizens. The persecution of the Jansenists was another consequence of the king's intolerance.

The foreign wars of Louis XIV. proceeded in great measure from the same ruling principles or prejudices of his mind. He disliked the Dutch, whom he considered as mercantile plebeians, heretics, and republicans.

The first war of Louis XIV. against the Emperor

Leopold, Holland, and Spain, was ended by the treaty of Nimeguen, 1678. Louis kept the Franche Comté and part of the Spanish Netherlands. The war broke out again in 1689, between Louis on one side, and the Empire, Holland, and England on the other. In Germany Louis XIV. caused one of the most atrocious acts recorded in the history of modern warfare. This was no less than the devastation of the Palatinate by his commanders. A district of more than thirty English miles in length, with the towns of Heidelberg, Mannheim, Speyer, Oppenheim, Creutznach, Frankenthal, Ingelheim, Bacharach, Sinzheim, and others, was ravaged, plundered, and burnt, in cold blood, under the pretence of forming a barrier between the French army and its enemies. A cry of indignation resounded throughout all Europe at the disastrous news. The treaty of Ryswick, in 1697, terminated the war, by which Louis was compelled to acknowledge William III. as king of Great Britain and restore the duke of Lorraine to his dominions.

The third war of Louis was that of the Spanish succession. It began in 1701, and lasted thirteen years, convulsed all Europe, was illustrated by the splendid victories of Marlborough, and was terminated at last by the peace of Utrecht in 1713. Louis succeeded in establishing a Bourbon dynasty in Spain, but this was the only advantage he gained. He died September 1, 1715, seventy-seven years of age.

LOUIS XV., born in February, 1710, was the only surviving son of the duke de Bourgogne, eldest son of Louis the Dauphin, son of Louis XIV. The dauphin died in 1711, and his son the duke of Bourgogne in 1712. The mother of Louis XV. was Maria Adelaide of Savoy, who died in 1712. Philippe d'Orléans, son of Philippe de France, brother of Louis XIV., and the head of the actual Orléans branch of the Bourbons, was appointed regent. He had acquired an unfavourable reputation as a man of licentious habits, equally destitute of religious and moral principles. But he began well: he reformed several of the most outrageous abuses of the late reign, he liberated a number of individuals who had been for years immured in the Bastille, he enforced economy, reduced the army, supported the general peace of Europe, courted the friendship of England, and concluded the triple alliance of the Hague in 1717, between France, England, and Holland. Unfortunately, the depressed state in which he found the finances made him listen to the wild schemes of Law, which ended in disappointment and the ruin of thousands of families. [LAW, JOHN.]

The discovery of a conspiracy, encouraged by Philip of Spain against the Regent, led to a war with that country. But peace was concluded in 1720. In 1722 Dubois, who had been made a cardinal, became prime minister of France.

In February, 1723, Louis XV., having completed his fourteenth year, was declared of age, and the regency of the duke of Orléans terminated. Dubois died the same year, and the duke of Orléans a few months after. The duke of Bourbon Condé was made prime minister, and governed France until 1726. Louis married, in 1725, Maria Leeczinska, daughter of Stanislaus, ex-king of Poland, and in the following year the duke of Bourbon was dismissed from the ministry, and the Abbé de Fleury substi-

tuted for him. The seventeen years of Fleury's administration, which ended with his death in 1743, were the brightest period of this reign. Fleury restored order in the finances, and credit and commerce revived. In 1733, on the death of King Augustus II., the war of the Polish succession broke out, when Louis XV. took the part of his father-in-law Stanislaus against Austria and Russia, who supported the son of Augustus. [AUGUSTUS III.]

Hostilities were carried on between France and Austria both on the Rhine and in Italy. France gained great success in this war; but that of the Austrian succession, which broke out in 1741, involved her in ruinous expenses to no purpose. In her struggle with the English in America, which arose out of the Seven Years' War, France was equally unfortunate. By the peace of Paris, February, 1763, she formally ceded Canada, Nova Scotia, and her other North American colonies, besides Granada, Dominica, and Tobago, in the West Indies; her navy never after recovered from its losses, her finances were exhausted, and her commerce destroyed. The king had now abandoned himself to gross licentiousness, and had become careless of state affairs. The mad attempt of Damiens alienated him still more completely from his people. [DAMIENS.] After the death of his mistress, the marchioness of Pompadour, he became attached to more vulgar women [BARRY, MARIE JEANNE], and at last formed a regular harem after the fashion of the eastern sultans, which was called the *Parc aux Cerfs*.

Louis died at Versailles, on the 10th May, 1774, sixty-four years of age. Two sons whom he had had by his wife were both dead: the eldest, the dauphin, died in 1765, and left by his wife, a Saxon princess, three sons, who have been in succession kings of France, namely, Louis XVI., Louis XVIII., and Charles X. Louis XV. had also by his wife several daughters, besides illegitimate children.

LOUIS XVI., grandson of Louis XV., succeeded him in 1774, being then twenty years of age. He had married, in 1770, Marie Antoinette, archduchess of Austria, sister of Joseph II. He chose for his minister of finance Turgot, an honest and enlightened man, who, in concert with his colleague Malessherbes, wished the king to institute various reforms, which, had they been carried out, might perhaps have prevented the Revolution. But the clergy and the nobility strongly opposed these projects, the parliaments themselves were averse to such changes, and Turgot was dismissed. Louis, however, following his own natural disposition, effected much partial good. The deficiency in the treasury, and the debt of four thousand millions of livres left by Louis XV., were the great stumbling-block of Louis' administration. He, however, went on for some years, during which he engaged in a war against England and an alliance with her revolted American colonies. In September, 1783, peace was concluded at Versailles; England acknowledged the independence of the United States, and gave up to France Tobago and the coast of Senegal.

Meantime the financial embarrassment of the French government went on increasing. Necker, a Genevese banker, wealthy and retired from business, having become minister of finance in 1776, effected many reforms. But in November, 1783, by

a court cabal he was dismissed, and Calonne substituted in his place. Calonne soon found it impossible to reorganize the finances; and after the Assembly of the Notables, which had been convoked for the purpose, had also failed to settle the question, and several successive ministers had tried in vain to supply the financial deficiency, Necker was recalled. He stated to the king that the only resource left was to call together the States-General of the kingdom, which had not been assembled since 1614. The king convoked them at Versailles in May, 1789. These states had always consisted of the three orders—clergy, nobility, and the third estate, or commons. Each order formed a separate house; and as a majority of orders decided, any project of law displeasing to the two privileged orders was sure not to pass those two houses, and was therefore lost. Necker, to obviate this difficulty, proposed to make the number of the third estate equal to that of the other two orders, which was done, and this was in fact the beginning of the Revolution.

The third estate was joined by many of the nobility, and, having thus gained the ascendancy, constituted itself the National Assembly, and changed the constitution to a limited monarchy. But it closed its sittings on the 30th September; and the result of a general election was that the majority of the new representatives were either Jacobins or Girondists. The rest of the history of Louis XVI. is well known. He was put to death by the guillotine, January 21, 1793; and his queen, Marie Antoinette, was executed in the following October.

LOUIS XVII., Duc de Normandie, second son of Louis XVI., remained in prison in the Temple after the death of his parents, and there he died of disease in consequence of ill treatment and privation, on the 9th of June, 1795. He was then ten years of age. He had been styled Louis XVII. by the royalists after his father's death.

LOUIS XVIII. was born in 1755. He was the brother of Louis XVI., during whose lifetime he was styled 'Monsieur.' Although styled king while exiled in England and elsewhere, he did not begin to reign until after the fall of the Emperor Napoleon. He granted his subjects a liberal charter, which continued to be the fundamental law of the kingdom, with the exception of some alterations made in 1830, until the Revolution of 1848. On the return of Napoleon from Elba [BONAPARTE], Louis was obliged to escape to Ghent; but the victory of Waterloo, June, 1815, again opened to him the way to Paris.

The new Chamber of Deputies, which was elected under the excitement of this second restoration, proved ultra-royalist in principle, and went further than the king. At last Louis dissolved the chamber. In the new elections the moderate constitutional party regained the ascendancy, and the king, in 1818, appointed a liberal ministry, at the head of which was placed Count Décazès. But the assassination of his nephew the duke of Berry by a fanatical republican in February, 1820, alarmed Louis, and restored the influence of the ultra-royalists. Décazès was dismissed, and Villèle was placed at the head of the ministry. The law of election was altered, the newspapers were placed under a censorship, and other measures of a retrograde nature were adopted.

No open violation of the constitution, however, was committed. In September, 1824, Louis XVIII. died, and was succeeded by his brother Charles X. He published, in 1823, the account of his emigration, '*Relation d'un Voyage de Paris à Bruxelles et Coblenz*,' which is curious.

For the other French sovereigns of this name, see FRANCE.

LOUIS-PHILIPPE, ex-king of the French, was born at Paris in 1773, and was the eldest son of Philippe Joseph, duke of Orleans, the notorious Duc d'Égalité of the Revolution. He was carefully educated under Madame de Genlis, the eminent French writer. The title he bore in his youth was duc de Chartres; and he was then distinguished by many traits of liberalism and manly courage. In 1791 he was put in command of the 14th Regiment of Dragoons; and war having been declared against Austria in 1792, the duke entered upon his first campaign. He was actively engaged in the battles of Valmy and Jemappes, under Kellermann and Dumourier. During the violence of the Revolution the duke's father was put to death, and a few months afterwards he himself, with General Dumourier, was summoned before the Committee of Public Safety; but knowing the sanguinary character of that tribunal, they both effected their escape into the Belgian Netherlands. He then retired into private life, honourably refusing to accept the Austrian offers to take up arms against his own country. He proceeded to Zurich; whence he was soon obliged to fly, and wander, with very inadequate means, through the different countries of Europe. At length, being only twenty years of age, he obtained the situation of teacher in the academy of Reichenau, a village in the south-east of Switzerland, where he passed under the name of Chaboud-Latour. In 1794, his retreat having been discovered, he was obliged to fly, when he travelled, chiefly on foot, through Norway, Sweden, Finland, and Denmark, under an assumed name. The French Directory having in vain endeavoured to discover the place of the young prince's retreat, at length entered into negotiations for permitting him to go to the United States, to which he departed in September, 1796. In the following November he was joined by his two younger brothers at Philadelphia. They soon afterwards travelled through the western country; then proceeded to New Orleans, and subsequently to Havannah, and the Bahama Islands. From the last place they embarked for New York, and thence sailed in a private vessel to England, where they arrived in February 1800, and took up their residence at Twickenham. Here their time was chiefly passed in study: and no event occurred worth noticing, until the death of his two brothers, the duc de Montpensier, and the comte de Beaujolais, in 1807 and 1808. After fifteen years' separation he met his sister, the Princess Adelaide; and they went together in quest of their mother, whom they found at Minorca. The three then set sail for Sicily, where they had been invited by King Ferdinand. Here the duke contracted marriage with the daughter of the king, the Princess Amelia, in November, 1809. No event of importance occurred until the abdication of Napoleon, and the restoration of the Bourbon family to the throne of France, in 1814. The duke set sail immediately,

and arrived at Paris on the 18th of May, when he was soon put in possession of the honours and estates to which he was entitled. On the return of Napoleon from Elba, he was again obliged to quit France. But after the Hundred Days he revisited his native country, where he lived in comparative retirement, until the startling revolution of 1830 drove Charles X. from the country, and elevated the duke of Orleans to the throne. The friendly feeling of England towards the new order of things was illustrated by the mutual visits of Queen Victoria and Louis-Philippe, in 1843; when the king of the French was invested with the order of the Garter.

During a period of seventeen years Louis-Philippe sat peaceably on the throne of France, and contributed largely by his policy to the prosperity and greatness of the country. But at length he evinced a family sordidness, especially as regarded his son's matrimonial alliance with the Infanta of Spain, that disgusted not only France but all Europe; and in 1848 he was ignominiously driven from the throne by that very populace who had been the instruments of his previous elevation. He fled from Paris, and landed at Newhaven, in March, 1848; when Claremont, the property of his son-in-law the king of Belgium, was assigned him as a residence. Here he chiefly lived in retirement with his family until his death, which took place in August, 1850. He was privately interred at the Roman Catholic chapel at Weybridge, in Surrey.

LOUIS D'OR, a French gold coin first struck in 1640, in the reign of Louis XIII. It was valued at from 16s. 7d. to 18s. 9½d. and continued in use till 1726, when it ceased to be a legal tender. Louis d'ors, however, continued to circulate in Germany and Switzerland, where they had a certain fixed value, and upon the return of the Bourbon family to France, in 1814, their use was revived in that country, their value then being twenty francs. They are now replaced by the Napoleon.

LOUIS, ST. [MISSOURI.]

LOUISBOURG. [CAPE BRETON.]

LOUISIADE ISLANDS is the name of an extensive group of islands situated in the Pacific Ocean, south-east of the great island of Papua, or New Guinea, between 8° and 12° S. lat., and 150° and 155° E. long.

They occupy a space of more than 300 miles from N.W. to S.E., but none of them appear to be large. The inhabitants belong to the race of the Papuas, and are very averse to any intercourse with foreign vessels which visit the dangerous sea that washes their southern coast.

LOUISIANA, the most south-western of the United States of North America, comprehends the countries on both sides of the Mississippi, between 28° 56' and 33° N. lat., and 88° 50' and 94° 30' W. long. It is bounded S. by the Gulf of Mexico, W. by Texas, E. by the state of Mississippi, and N. by that of Arkansas. The greatest length, N. to S., is 290 miles; the greatest breadth, E. to W., is 210 miles. The area is 41,255 square miles. The population in 1860 was 708,002, of whom 376,280 were free, and 333,010 slaves.

Surface and Soil.—Louisiana presents a great variety of surface, though it is a plain country, and only in a very few places rises into hills of moderate

elevation. The southern part of the state comprehends the whole of the delta of the Mississippi, which below the mouth of the Red River divides into several branches. The most western of these branches is the Atchafalaya, which leaves the main stream about three miles below the mouth of the Red River, and falls into Atchafalaya Bay, in the Gulf of Mexico. The southern part of the state consists to a considerable extent of swamps and marshes, and a large part of it is annually overflowed by the Red River and the Mississippi. By this overflow more earth is deposited on the margin of the Mississippi than farther back. This rich alluvial deposit extends 400 yards, and in some places a mile and a half from the river; and to regulate the overflow, and prevent the valuable land in the rear from being inundated, an artificial embankment, called the *Levee*, is raised on both banks of the river. On the eastern side the embankment commences 60 miles, and on the western, 172 miles, above New Orleans. The northern part of the state has an undulating surface, and a heavy natural growth of timber, consisting of pine, oak, hickory, walnut, and other trees. In fact, the greater portion of this state is covered with forests, which are, however, more swampy than those of the other southern states.

Rivers.—The chief rivers in this state are the Mississippi and its affluent, the Red River. [MISSISSIPPI, River.] The Sabine River, on the west, separates Louisiana from Texas as far as 32° N. lat.; and the Pearl River on the east, in the lower part of its course, separates the state from that of Mississippi. Several other rivers flow through the state, of which the largest are the Washita, which falls into the Red River, and the Calcasieu, which falls into the Gulf of Mexico. Lakes (which are mostly formed by expansions or overflows of the rivers) are numerous in this state; Pontchartrain is the largest.

Products.—There is a great quantity of exceedingly rich land in Louisiana, and large quantities of cotton, sugar, rice, maize, indigo, and tobacco, are produced. Large herds of cattle are fed in the natural meadows, and also great numbers of horses and mules. Panthers, deer, &c., are numerous, and alligators swarm in the waters. The winters are mild, the summers very hot, and in the marshy parts very unhealthy, being liable to visitations of yellow and bilious intermittent fevers. The soil is laid out in fine plantations along the river banks. Oranges, and most other southern fruits, are grown in abundance. The manufactures and minerals are of little importance. There are salt springs in the northern districts, and coal and iron ore are found in the north-western corner of the state.

Chief Towns.—Louisiana is divided into forty-seven parishes, answering to the counties of other states. The principal towns are NEW ORLEANS, the capital, *Baton-Rouge*, and *Natchitoches*. The latter (pronounced *Nakitosh*), 368 miles north-west by west from New Orleans, is situated at the foot of a bluff on the west bank of the Red River, 200 miles above its junction with the Mississippi. It has considerable trade, and a population of about 2000, half of whom are French. The place was settled by them in 1717. *Baton Rouge*, the seat of the legislature, is 129 miles above New Orleans, on the left bank of

the Mississippi, and has a state capital, a college, United States arsenal, and barracks. The population is about 6000.

Several railroads and canals radiate from New Orleans in various directions. Owing to the great facilities of water carriage, railways were much deferred, but they have recently been constructed in the state in all directions. The state seceded from the Union early in the late war. Its capital was taken by the Federals in 1862, and was subject to military government until the close of the struggle.

Louisiana was originally settled by Roman Catholics, and they are still the most numerous sect. A large portion of the population are of French or Spanish descent.

The constitution of Louisiana was formed in 1812, in which year it was constituted a state. The governor is elected for four years, and receives 6000 dollars a year. The legislature consists of thirty-two senators, who are elected for four years, and ninety-eight representatives, who are elected for two years. Louisiana sends two senators and four representatives to Congress.

The country called Louisiana, a term which comprised much more than the present state, was first explored by the French, and was so named after Louis XIV. A colony was settled in 1699. In 1717 the interest in the province was transferred to a chartered company, at the head of which was John Law, whose Mississippi speculation was a ruinous failure. In 1731 the company resigned its rights to the English government, by which in 1762 the whole of Louisiana was ceded to Spain. In 1800 the province was transferred by the Spaniards to the French, of whom it was purchased by the United States in 1803 for 15,000,000 dollars.

LOUISVILLE. [KENTUCKY.]

LOULE', a town of Algarve, Portugal, in a broad and fertile valley, 8 miles north of Faro. The town, which is surrounded by walls, contains about 5000 inhabitants, several churches and monasteries, and gives the title of Marquis to a noble Portuguese family.

LOURDES. [PYRÉNÉES, HAUTES.]

LOUSE. [PEDICULUS.]

LOUTH, a maritime county of the province of Leinster in Ireland, is bounded N. by Armagh and Down; E. by the Irish Channel; S. and S.W. by Meath; and W. by Monaghan. It lies between 53° 43' and 54° 7' N. lat., 6° 6' and 6° 41' W. long. The greatest length, N. to S., is 25 miles; the greatest breadth, E. to W., is 15 miles. The area is 315 square miles, or 201,434 acres, of which 178,972 are arable, 15,603 uncultivated, 5318 in plantation, 1200 in towns and villages, and 813 under water. The population in 1861 (including the town of Drogheda) was 90,713, of whom 83,020 were Roman Catholics, and 6234 belonged to the Established Church. In 1851 the total population was 107,657.

Surface and Rivers.—From the Boyne to the river of Dundalk, the county is mostly flat. The only eminences in this division at all conspicuous are in the southern part of the county; the chief among them are Belpatrick, Mount Oriel, Tullyesker Hill, and Clogher-head. The Mattock River forms a boundary between Louth and Meath. The undulating plain, which extends from the hills to the river

of Dundalk, is watered by the Dee, the Glyde, the Fane, the White, the Lagan, and other small rivers. Most of this district is under tillage, and in good cultivation.

Beyond the Castletown River the surface is of quite a different character. A group of mountains, ranging from 1000 to 1900 feet in height, and extending over a district 15 miles long and 5 miles broad, stretches across the Armagh border, and extends eastward into a great peninsula forming the northern boundary of the Bay of Dundalk and the southern limit of the Lough of Carlingford and basin of the Newry River. This group is divided into two nearly equal portions by a ravine traversing it from north to south, and forming a direct line of communication between Dundalk and Newry. Through this defile the great northern road is carried at a considerable height above the bed of a mountain stream. The Kilcurry River, descending from the southern declivities, joins the Castletown River a short distance above the bridge of Dundalk. The glens and vales which lie along this border of the mountain region possess much picturesque beauty. From the eastern side of Ravensdale the mountains stretch back to the river of Newry and Bay of Carlingford, which they overhang in masses rising almost immediately from the water's edge. Towards the extremity of the peninsula and along that side bounding the Bay of Dundalk the mountains leave a considerable margin of level land between them and the sea; indeed most of the coast is skirted by a broad sandy beach. Louth is the smallest county in Ireland, and is intersected by 565 miles of roads.

Geology, Soil, Productions.—The level portion of the county south of the river of Dundalk belongs generally to the clay-slate formation. Patches of carboniferous limestone occur in many parts of the county, skirted by yellow sandstone. The mountainous region consists of a nucleus of granite supporting the clay-slate and limestone of the surrounding field on its flanks. A great protrusion of crystalline greenstone trap occurs at the eastern extremity of the range. Iron and lead ore are the only minerals which have been observed, but nowhere in sufficient quantity to warrant mining operations. The soil of the southern division of the county is well calculated for every kind of grain crop. Farming in general is carried on in a superior manner. Green crops are grown by almost all the gentlemen farmers. The fences are usually of quickset, and the lands well drained. In the mountain district the condition of the people is much inferior, and the improved system of husbandry unknown. The principal crops are corn and beans, potatoes, turnips, and clover.

The manufacture of linen is prosecuted with some activity at Ravensdale and Collon, where there are large bleach-works, but chiefly in Drogheda and its neighbourhood, where the trade is generally very brisk. The fisheries off the coast give occasional employment to several hundred persons.

Divisions and Towns.—Louth is divided into six baronies and sixty-four parishes. It is mostly in the archdiocese of Armagh, and in the north-eastern circuit, the assizes being held at Dundalk. The county returns two members to Parliament, and the borough of Dundalk has one representative. The number of voters on the parliamentary register for

the county in 1865 was 2441. The following are the principal towns, with the population of each in 1861:—

Ardee, a market town 14 miles N.W. by N. from Drogheda, is situated on the north side of the small river Dee. It appears to have been a place of some importance formerly, but now consists of one main street, with several lanes branching from it. There are remains of two ancient castles, one of which has been fitted up as a court-house. The church, which originally belonged to a monastery, is a plain building, and there is a commodious Roman Catholic chapel. Population, 2580. A considerable trade in malt and corn is carried on here. Ardee is governed by a Board of Commissioners, elected under the Towns Improvement (Ireland) Act, 1854. The name is a corruption of *Atherdee*, 'town on the Dee.'

Carlingford, a small fishing town, chiefly consisting of cabins inhabited by fishermen, is situated 14 miles E. by N. from Dundalk, on the south side of Carlingford Lough. Population, 777.

Drogheda. [DROGHEDA.]

Dundalk, the county town, a parliamentary borough and port, is situated 21 miles N. by W. from Drogheda, at the head of Dundalk Bay and at the mouth of the Castletown River. The town contains a county court-house, guild-hall, prison, barracks, market-house, linen-hall, parish church, Roman Catholic and other chapels, friary, two convents and schools, exchange, infirmary, custom-house, free library, and three endowed schools. There are several tanneries, flax and flour mills, salt works, a brewery, and a distillery. The harbour is good, the fisheries important, and timber, slates, coal, and all kinds of agricultural produce are exported in considerable quantities. Steamers ply regularly to Liverpool four times a week. The total number of vessels which entered the port in 1864 was 926 (143,571 tons), and the clearances were 337 (98,091 tons). The customs revenue in 1865 was 32,182*l*.

The borough returns one member to Parliament: constituency about 280. The port and harbour are in progress of improvement. The river has been straightened, and the bar and harbour deepened by steam-dredging from 5 to 8 feet, so that vessels drawing 16 feet water can now come up. The channel, when completed, will be 150 feet wide at the quays, and 300 feet at the point. The rise of tide at the bar is 18 feet. A lighthouse on the screw-pile principle has been erected at the bar within the last few years, and recently a fog-bell at a cost of 250*l*. Population, 10,464.

History and Antiquities.—Louth, at the time of its invasion by the English, formed a portion of the territory of Orgial or Oriel. The eastern part of Orgial, constituting the present Louth, having been conquered by De Courcy between 1179 and 1180, was erected into a county by King John in 1210. Louth was not considered a portion of Leinster until the reign of Elizabeth. The forfeitures consequent on the rebellion of 1641, and the ensuing civil wars, extended over nearly the entire county.

The numerous antiquities which occur in Louth have been made the subject of a volume entitled 'Louthiana,' published at Dublin in 1758. Of the earthen mounds and intrenchments the most remarkable in the county is that of Castle-Guard at Ardee.

Its perpendicular height is nearly 90 feet, the depth of the main trench between 30 and 40, the circumference at the top 140, and round the base upwards of 600 feet. There is another earthen intrenchment near Dundalk; stone circles at Ballirickan and Ballinahatry; a cromlech at Ballymasculan; round towers at Dromiskin and Monasterboyce; and remains of two others at Louth and Drogheda. Two beautiful stone crosses stand near the tower of Monasterboyce. The ruins of the abbey of Mellifont occupy a picturesque site on the banks of the Mattock River, near the Boyne. There are some very ancient ruins on the hill of Faughart, where Edward Bruce is said to be buried, connected with the old cell of St. Brigid. Of the various feudal buildings throughout the county the chief are the castle of Carlingford, erected by King John; Rohe's Castle, north-west of Dundalk; Torfeckan or Termonfeckin Castle, a residence of the archbishops of Armagh, inhabited last by Primate Usher; and Castletown, still kept in habitable order, on the south bank of the Castletown River, near Dundalk.

LOUTH. [LINCOLNSHIRE.]

LOUTHERBOURG, PHILIP JAMES DE, was born at Strasburg, October 31, 1730, and studied under his father and Casanova. After having been admitted a member of the Paris Academy in 1768, Louthembourg came over to England, was elected a royal academician in 1771, and was engaged as scene-painter at the Opera House. Soon after his settling in this country, he got up, under the name of the *Eidophusikon*, an exhibition displaying the changes of the elements and their phenomena. Two of his chief pictures were, Lord Howe's Victory in 1794, and the Battle of the Nile. He resided in London till his death in 1812.

LOUVAIN. [BRABANT, SOUTH.]

LOUVIERS. [EURE.]

LOUVOIS, FRANÇOIS MICHELLETELLIER, MARQUIS DE, an eminent French statesman, was born in Paris, January 18, 1641. He early entered upon a political career, and having succeeded his father as chancellor and war minister, displayed a sagacity and an energy which secured him Louis XIV.'s entire confidence. To render it impossible for the king to do without him, he promoted by every means in his power a warlike policy, and it must be owned that he evinced a consummate ability in carrying it out. With him the end justified the means, and he accordingly authorized the desolation of the Palatinate in 1674, one of the darkest deeds in the whole annals of war. From 1666 until 1691 he retained in his hands the administration of the kingdom, directed the campaigns of Turenne and Condé, and contributed to the aggrandizement of France and the development of her resources. He entirely reorganized the French armies. He founded and repaired military schools, and erected the famous *Hôtel des Invalides*. Yet, as a statesman, his views were narrow, and he was mainly responsible for the revocation of the Edict of Nantes—an act which did more harm to France than all the victories of her generals could remedy. His later years were embittered by frequent quarrels with Madame de Maintenon, who resented his arrogant assumption of power, and endeavoured to prejudice the mind of Louis against his proud but able minister. Louvois died on the

16th of May, 1691, in the fifty-first year of his age.

LOUVRE (French, *l'ouvert*). A dome or turret rising out of the roof of the hall in our ancient domestic edifices, formerly open at the sides, but now glazed. They were originally intended to allow the smoke to escape, when the fire was kindled on 'dogs' in the middle of the room. The open windows in church towers are called *louvre windows*, and the boards or bars, which are placed across them to exclude the rain, *louvre boards*.

LOVAT, LORD. Simon Fraser, afterwards Lord Lovat, was born in 1676 at Beaufort, near Inverness. The principal events of his life are connected with the two rebellions of 1715 and 1745, in which he played false both to the Stuarts and the Hanoverians. Previous to the first rebellion he was despatched by the 'Old Pretender' to Scotland, with proper credentials, arms, ammunition, and money to promote the rising. But he betrayed his trust, and fought on the side of the king, for which he received his title and estates. In 1745 he joined the party of Charles Edward, not in his own person, but by means of his son, whom he sent with the Frasers. His complicity in this design being discovered, he was arrested, tried by his peers, sentenced to death, and executed on Tower Hill, April 9, 1747. He died with a courage worthy of a better man.

LOVE, FAMILY OF, a religious sect which flourished in Europe during the middle age. Their doctrines were first promulgated in Holland by Nicholas of Leyden; and made their appearance in England about the year 1580. From their pretended sanctity the sect obtained a great number of followers among the lower orders; but Queen Elizabeth ordered their books to be burnt, and adopted measures for their suppression.

LOVE-APPLE, a fruit-bearing annual, also called Tomato, is the *Lycopersicum esculentum* of botanists, a plant much cultivated for the sake of its berries, from which are obtained various preparations used for culinary purposes. It is a native of Peru and Brazil, whence it has been carried into North America and the Old World; and it has become, as it were, naturalized in some parts of India.

LOVE-BIRD (*Psittacula*), a genus of birds of the *Psittacidae*, or parrot family, which flourish in the warm regions of America, Australia, and Africa. They receive their name in homage to the warm mutual affection which under all circumstances they exhibit. An Australian species is now common as a cage bird in our own islands, and may be fed in the same manner as the canary.

LOVELACE, RICHARD, born in 1618 at Woolwich, was the son of a Kentish knight. He entered the army under the patronage of Goring. The county of Kent deputed him to present their petition in favour of the king to the Long Parliament; for which he was imprisoned in the Gatehouse, and released only on giving bail in forty thousand pounds. In 1646 he raised a regiment in the French service, and was wounded at Dunkirk. Returning to England in 1648, he was again imprisoned, and remained in confinement till after the king's death. In 1649 he published 'Lucasta: Odes, Sonnets, Songs,' &c., the lyrical pieces in which have much spirit and vigour. He also wrote two plays, which were never published.

He died of consumption, and in great distress, in a mean lodging in London, in 1658.

LOVERC. [BERGAMO.]

LOW COUNTRIES, a district in the north of Europe, comprehending the kingdoms of the NETHERLANDS and BELGIUM, and grand duchy of LUXEMBURG.

LOWELL. [MASSACHUSETTS.]

LOWESTOFT. [SUFFOLK.]

LOW-SUNDAY. The Sunday next after Easter is popularly so called in England.

LOW-WINES. The liquor produced by the first distillation of molasses or fermented liquors.

LOWTH, WILLIAM, born 1661, died 1732. He was brought up at Merchant Taylors' School, whence he was sent to St. John's College, Oxford. Early in life he became chaplain to Mew, bishop of Winchester, who gave him a prebend in the cathedral of Winchester, and the rectory of Buriton in that diocese, where he lived, died, and was buried.

If we would form an idea of the extent of his laborious reading, we must look rather to the works of other persons than his own, and particularly to Potter's edition of the works of Clemens Alexandrinus, and Hudson's edition of the works of Josephus. To both these editors he communicated valuable notes. Of his own writings, those which are now most read are his 'Directions for the Profitable Reading the Holy Scriptures,' which was first published in 1708, and has been often reprinted, and his 'Commentary on the four greater Prophets.'

LOWTH, ROBERT, born 1710, died 1787, a prelate of the English Church, son of William Lowth last named, and, like his father, distinguished by his knowledge of the books of Scripture, and his valuable writings in the illustration of them. He was also an elegant scholar, and an inquirer into minute and curious history.

He was educated in Winchester College, whence he passed to New College, Oxford. In 1766 he became Bishop of St. David's; in the same year he was translated to Oxford; and in 1777 was made Bishop of London.

His 'Life of William of Wykeham,' published in 1758, is an admirable specimen of the results to be attained by curious and recondite biographical research. His 'Lectures on the Poetry of the Hebrews' were delivered by him at Oxford, when he was professor of poetry. They were received with great respect by the learned, not of England only, but of the Continent, where they were reprinted, with valuable notes by Michaelis. These lectures were published by Lowth in Latin, the language in which they were delivered; but there is an English translation by Dr. Gregory. In 1778 he published a 'Translation of the Prophet Isaiah,' distinguishing the poetical from the parts written in prose, and exhibiting the various forms of Hebrew parallelisms which occur in that prophet. He also published an 'Introduction to English Grammar.'

LOXA, or LOJA, a town of Spain, in the province of Granada, 30 miles west of Granada, at the north base of a ridge of hills, and in a valley watered by the river Gemil. It has manufactories of coarse woollens and paper, a clerical college, two hospitals, three churches, a convent, and is the head of a judicial district. Population, 15,698.

LOXIA, the *Cross-bill*, a genus of passerine birds belonging to the family *Fringillide*. The generic characteristics of the Cross-bills are—Bill moderate, strong, very much compressed; the two mandibles equally curved, hooked, and the elongated points crossing each other. Nostrils basal, lateral, rounded, concealed by hairs directed forwards. Feet with three toes before and one behind; anterior toes divided. Wings moderate, the first quill longest. Tail forked. The species are very few, and confined

Common Cross-bill (*Loxia curvirostris*).

chiefly to the northern parts of Europe and America. The best known is the Common Cross-bill, *L. curvirostris*, which is frequently met with in Britain during the summer. Their chief food is the seeds of coniferous trees. The structure of their bills is well fitted for opening up the cones. They are also fond of the seeds of apples, and commit great havoc when a flock of them appears in an orchard.

LOYOLA, IGNATIUS. *Don Iñigo Lopez de Recalde*, more generally known under the name of Loyola, was the youngest child of Don Bertram, lord of Oñez and Loyola. He was born in 1491, at the castle of Loyola, in Guipuscoa. In early youth he was attached to the court of Ferdinand and Isabella in the quality of a page, and afterwards distinguished himself as a soldier. In his thirtieth year, while assisting in the defence of Pampeluna against the French, he was severely wounded. A long and painful confinement was the result. To relieve its weariness he was furnished with works of mystical devotion and the lives of saints. He has graphically described the various scenes through which he passed in his introduction to a religious life, in his 'Spiritual Exercises.' From this time all his desires were directed to one great object—an entire devotion to the service of God. He resolved upon retiring to a Benedictine monastery at Mount Serrat, in order to prepare himself for a pilgrimage to the Holy Land. On his return he passed the vigil of the Annunciation, March 24, 1522, in the church of the Holy Virgin, at Mount Serrat; on its altar he hung up his arms, the trophies of his worldly triumphs, and vowed obedience to the commands of God's church. He determined to perform barefoot his intended pilgrimage, and in the coarse raiment of a beggar. On leaving Mount Serrat, he went to the hospital of the Dominican convent at Manresa, where his deeds of charity soon acquired for him celebrity in that town, and the admiration of the multitude, to avoid which he retired

to a cavern at a short distance from Manresa, where he redoubled the severity of his penances, and was one day found in a state of inanimate exhaustion at the door of his cell. After residing ten months at Manresa, he left for Barcelona, whence he embarked for Rome. In that city he obtained the blessing of the pope, Adrian VI., upon his enterprise, and resumed his journey alone, fasting daily and begging alms. From Cyprus he embarked with some pilgrims for the Holy Land, and reached Jerusalem September 4, 1523. He was refused permission of residence from the primate of the Church of Rome at Jerusalem. He reached Venice in January, 1524, and thence he returned to Barcelona. In this town he determined upon making some stay in order to study. At the age of thirty-three he began to apply himself to the rudiments of grammar. He continued studying at Barcelona till the attempts on his part to reform some irregularities in a convent of nuns exposed him to the vengeance of those who had partaken in their disorders. He then retired to the University of Alcalá. A religious address which he delivered to the students was the occasion of his dismissal from that university. In 1527 he went to Salamanca, where he fell under the displeasure of the Inquisition, who punished him by a severe confinement, and dismissed him from their city. He next repaired to Paris, where he arrived in February, 1528. He applied himself to the studies of the university, humbly placed himself in the class of the least advanced scholars, and besought their teacher to treat him as one of them. Two students shared his rooms, Peter Faber and Francis Xavier of Navarre. The three companions formed the closest intimacy, sharing each other's toils and gains. Shortly after, three more students joined his small society. On August 15, 1534, they assembled at the church of Montmartre, where they took the solemn vows of chastity, absolute poverty, devotion to the care of Christians, and to the conversion of infidels. The further history of the religious community thus established has been told under the head of **JESUITS**.

On September 27, 1540, Paul III. sanctioned, under some limitations, the establishment of the order, and finally, in 1543, made the sanction unconditional. Loyola was chosen president. He remained at Rome as the centre from which he was to direct the movements of the society. His time was spent in revising its constitutions, and in works of charity. He founded an asylum for the protection of Jews who had become proselytes to Christianity, and a penitentiary, where the victims of seduction might reform their lives. In the year 1546 Francis Borgia founded the first Jesuit college at Gandia in Spain. On July 31, 1556, Loyola died.

The memory of Ignatius was consecrated by beatification in 1609, and he was canonized as a saint by Pope Gregory XV. in 1622. His festival is celebrated on July 31.

His life has been written by Gonzales and Ribadaneira; by Maffei in Latin; and by Bartoli and Bouhours in French. His 'Spiritual Exercises' (*Exercitia Spiritualia*) were published at Rome in 1548, and have been translated into French by Drouet de Maupertuis and Clément. His 'Maxims,' translated, were published at Paris in 1683.

LOZENGES. In such cases as ulcerated or inflamed sore throat, chronic coughs, &c., lozenges

are often employed by medical men, so that the substances of which they are composed may only pass gradually into the stomach, and act as long as possible on the pharynx and laryngeal opening. They are generally composed of demulcent materials—such as farinaceous matter, sugar, isinglass, and gum—as such a combination delays the solution of the different products the longest possible time. Lozenges differ from drops in the fact that in the latter the sugar is first rendered fluid by means of heat, while no heat is employed in mixing the ingredients of lozenges.

LOZÈRE, a department in France, formed chiefly out of the old district of Gevaudan, lies between 44° 7' and 44° 58' N. lat., 3° and 4° E. long., and is bounded N. by Cantal and Haute-Loire, E. by Ardèche, S. by Gard, and W. by Aveyron. Its greatest length is 60 miles, and its mean width is 39 miles. The area is 1987 square miles, and the population 137,367.

Surface.—It is covered by the Cévennes mountains in the south-east, which rise in Mont Lozère (whence the name of the department) to the height of 4887 feet above the sea-level; by the Margeride chain in the east and north-east; by the Aubrac mountains [AVEYRON] in the centre and west; and in the south-west by high plains, called *caussées*, many of which are of great fertility. The melting of the snow, that lies on these mountains for several months in the year, gives rise to a great number of rivers, which drain the three slopes formed by the disposition of the masses before named. The north-eastern slope belongs to the basin of the Loire, and is drained by the ALLIER and some of its feeders; the south-eastern slope makes part of the basin of the Rhône, and is drained by Gardon-d'Alais and the Gardon-d'Anduze [GARD]; and the western slope, which is included in the basin of the Garonne, is drained by the river TARN, the LOT, and the Truyère [CANTAL].

Climate.—The mountains being snow-clad during a great part of the year, renders the climate severe for the latitude; winter lasts about four months in the southern part of the Cévennes, and is prolonged to six months in the north of the department; the spring is very rainy, and violent storms are frequent in summer.

Products.—The nature of the soil presents great obstacles to the labours of the farmer; yet in most instances the land everywhere that is capable of cultivation is well tilled. The chief crops raised in the north of the department are rye, some barley, oats, and hay; in the *caussées* wheat, barley, oats, fruits, &c., are grown; and in the Cévennes the chestnut and the potato are the chief support of the population. The vine is cultivated in some favourable situations; but the quantity of wine produced does not suffice for the consumption, and the same may be said for the cereal productions of the department. In the south-eastern slope of the department the mulberry is grown for the production of silk. The mountain pastures are extensive, and of excellent quality; great numbers of well-wooled sheep are reared. Horses are not numerous; but mules and horned cattle are. Amongst the wild animals are wolves, badgers, great numbers of hares and rabbits. Medicinal plants, and plants used in tanning and

dyeing, are abundant. The forest timber is composed of oak, beech, fir, chestnut, &c.

Natural Products, &c.—Iron, lead, antimony, silver, and copper, are found. In the Gardon and in the Cèze [GARD] particles of gold are found after heavy rains. Marble, porphyry, granite, gypsum, &c., are also met with. Mineral springs are numerous.

The manufactures are unimportant, and are nearly all for home use. The commerce of the department, owing to the want of water communication and good roadways, is confined to articles of mere necessity, and is altogether insignificant.

Divisions, Chief Towns, &c.—The department contains 1,276,756 acres, and is divided into three arrondissements, which, with their subdivisions and population, are as follows:—

Arronds.	Cantons.	Communes.	Pop. in 1863.
Mende, . .	7	63	47,744
Florac, . .	7	52	38,743
Marvejols, .	10	78	50,880
Total, . .	24	193	137,367

The arrondissement of Mende is named from its chief town, *Mende*, which is situated in a valley surrounded by high hills, on the right bank of the Lot, in 44° 31' N. lat., 3° 29' 41" E. long., and has a cathedral with two spires, an old episcopal palace, now the prefecture; a public library of 8000 volumes, a chamber of manufactures, and 6370 inhabitants. The town is surrounded by ramparts, which form a pretty walk; the streets, many of which are supplied with fountains, are narrow and crooked. There are some manufactures of coarse woollen cloths. About 8 miles from Mende, in the valley of the Lot, is *Bagnols-les-Bains*, a small village famous for its medicinal springs and warm baths. Population, 390. *Langoagne*, a small town, with an ecclesiastical school, and 3156 inhabitants, is situated on a high plateau near the source of the Allier, on the eastern border of the department. *Villefort*, a small place of 1536 inhabitants, situated at the foot of Mont Lozère, is important for its argentiferous lead and copper mines.

In the arrondissement of Florac, the chief town, *Florac*, is situated on the left bank of the Tarnon, a feeder of the Tarn, and has a tribunal of first instance, and 2141 inhabitants. *St.-Germain-de-Calberte*, S.E. of Florac, is situated in a district almost entirely covered with mulberry plantations, and has 1637 inhabitants, who raise a considerable quantity of raw silk. *Meyrueis*, near the southern border of the department, on the right bank of the Yonte, a feeder of the Tarn, has hydraulic saw mills, manufactures of hats, cheese, lace, wire for cards, and knitting needles. The population is 1995.

In the arrondissement of Marvejols, the chief town is *Marvejols*, which is situated in a valley planted with fruit trees, on the right bank of the Coulogues (a feeder of the Lot), 10 miles W. from Mende, and has a tribunal of first instance, a college, an ecclesiastical school, and 4848 inhabitants, who manufacture serges, woollen cloth and yarn, leather, bricks, &c. The town is regularly built, well paved, and ornamented with fountains. A canal from the river

Coulogues supplies the dye-houses of the town with water, and drives the machinery of several factories.

The department forms the see of the bishop of Mende, is included in the jurisdiction of the Cour Impériale of Nîmes, Academy of Montpellier, and belongs to the tenth Military Division, of which Montpellier is head-quarters. It returns one member to the Chamber of Deputies. (*Dictionnaire de la France; Annuaire pour l'An 1866*).

LÜBECK is situated in 53° 51' N. lat., 10° 41' E. long., on a long eminence between the rivers Trave and Wakenitz. Its territory is bounded E. by Mecklenburg-Strelitz, W. by Oldenburg and Holstein, and S. by Lauenburg; the northern part, between Holstein and Mecklenburg, extends to the Baltic. Its territorial possessions were formerly very scattered; some detached portions were in Holstein, some in Lauenburg, and others in Mecklenburg. By the decision of the diet in 1803, modified in 1804 by a treaty with Oldenburg, it obtained, in exchange for many of its distant districts, a continuous tract on the Trave. Lübeck is no longer a fortified town; the old ramparts are converted into public walks, and the city is very clean and cheerful. The interior is intersected by several broad and straight streets. The houses are built of stone. A great number of them are in the old-fashioned style, with the gable ends towards the street, but the more modern are in better taste. Besides the cathedral, which contains valuable paintings and remains of antiquity, there are seven churches, of which that of St. Mary (Marienkirche) is celebrated as one of the finest Gothic churches in northern Germany. It was completed in 1304, and has three naves and two towers, 382 feet high. Lübeck has a gymnasium, several charitable institutions, a school of design, a Roman Catholic chapel, and a Calvinist church. There are also an exchange, an arsenal, a mint, a valuable public library, and an operatic theatre. The senate-house, an ancient Gothic building, contains the hall where the deputies of the Hanseatic League formerly met.

The territory already mentioned, including the district of Vierlande, which Lübeck possesses in common with Hamburg, is 127 square miles in extent, with a population of 50,614, that of the city being 27,249.

Throughout the territory the soil is fertile, the principal occupation of the inhabitants being the rearing of live stock. The Stecknitz and the Trave are the only rivers of any importance.

The principal exports are corn, cattle, wool, fish, iron, and timber; the imports comprise wines, silks, cottons, hardwares, and other manufactured goods, colonial products, dye stuffs, &c. The city has an extensive commission and transit trade, and fairs for wool, cattle, and horses. There are manufactures of cigars, soap, playing cards, paper, linen and cotton stuffs, iron, copper, and brass works.

Lübeck communicates with Hamburg by railway and the Trave and Stecknitz Canal, and its trade is gradually reviving.

Lübeck has about sixty ships of its own, and the arrivals are above 1000 annually. The principal export and import trade is with Russia, Sweden, and Denmark; vessels of 9 feet draught can come up to the town, where they enter a spacious basin lined with quays; larger ships discharge their cargoes by

lighters at Travemünde, which is situated at the entrance of the Trave into the Baltic, and has a fine secure harbour. Travemünde is fortified, has a light-house, and public baths. It is 9 miles N.E. of Lübeck, has 1476 inhabitants, and is a pretty little town, much resorted to in the bathing season. Steamers ply from Travemünde to St. Petersburg, Copenhagen, Hamburg, Amsterdam, Stockholm, and Hull, &c. Small steamers convey passengers, &c., up the river to Lübeck daily.

In 1806 Lübeck was stormed by the French, and it subsequently became the capital arrondissement of the department of Bouches-du-Elbe. It was formerly the chief of the four free or Hanse towns, and is still a member of the Germanic Confederation. It contributes 679 men to the Federal army. The annual revenue and expenditure of the whole territory is between 70,000*l.* and 80,000*l.* The government was formerly purely aristocratic, but the city and state are now governed according to the constitution of December 29, 1851. The main features of this charter are two representative bodies, the Senate, exercising the executive, and the Bürgerschaft, or House of Burgesses, exercising the legislative authority. The Senate is composed of fourteen members, elected for life, and presided over by two burgo-masters, who hold office for two years each, and retire in rotation. There are 120 members in the House of Burgesses, chosen by all citizens who are members of any of the twelve colleges, or guilds of the town. A committee of thirty burgesses, presided over by a chairman elected for two years, has the duty of representing the legislative assembly in the intervals of the ordinary sessions, and of carrying on all active business. The House of Burgesses has the initiative in all measures relative to the public expenditure, foreign treaties, and general legislation; while the Senate, intrusted chiefly with the executive government, has also to give its sanction to the passing of every new law.

The High Court of Appeal for the four free cities of Germany—remnant of the old Hanseatic League—is established at Lübeck, and Lübeck law is of acknowledged authority in many questions.

LUBLIN. [POLAND.]

LUBLIN, the capital of the Russian province of Lublin, is situated on an eminence above the river Bistriz, in 51° 16' N. lat., 22° 30' E. long., and had, in 1861, 19,054 inhabitants. The city, which is surrounded with walls, ditches, and great lakes, is divided into an upper and lower town, of which the latter is chiefly inhabited by Jews. It has a dilapidated castle on a hill, and is the seat of a bishop and court of appeal. The most considerable buildings are the town-hall and the eighteen churches; there are also a Piarist college, a synagogue, the Sobieski palace, a gymnasium, several hospitals and charitable institutions. The town has three annual fairs, each lasting a month, and a considerable trade in woollen cloths, wine, corn, &c.

LUC, DE. [DELUC.]

LUC, LE. [VAR.]

LUCANIDÆ, a family of coleopterous insects, called Stag-beetles, from the extraordinary development of the mandibles of the males. Some of the foreign genera of stag-beetles are remarkable for brilliance of colouring. In Britain we have four

species, which belong to as many genera. Type, the Common Stag-beetle (*Lucanus Cervus*).

LUCANUS, MARCUS ANNEUS, was born at Corduba (Cordova) in Spain, A.D. 38. He was the son of M. Annæus Mela, the brother of the philosopher Seneca, and was carefully educated at Rome. His poetry recommended him to the notice of Nero, who bestowed upon him the dignity of quæstor and augur. Lucan did not, however, remain long in the imperial favour, for he was a poet, and his master affected to be one. Lucan, it is said, was forbidden to publish any more poems; and he entered into a conspiracy with Piso and others to assassinate Nero. (Tacitus, 'Ann.', xv. 49.) This conspiracy was detected, and the poet, being condemned to death, opened his veins A.D. 65.

Lucan wrote many poems; but the only one extant is the 'Pharsalia,' which celebrates the civil war between Cæsar and Pompey, and gives (in ten books) an account of its incidents from its commencement to Cæsar's visit to Cleopatra in Egypt. As the tenth book leaves off abruptly in the midst of a narrative, it is probable that the poet had not finished the work at the time of his death. The 'Pharsalia' contains many vigorous and animated descriptions, and the speeches are characterized by considerable rhetorical merit; but the language is often inflated, and the expressions extremely laboured and artificial.

The best editions of Lucan are by Oudendorp (1728), Burmann (1740), Bentley (1760), and Weise (1835). There are French translations of the 'Pharsalia' by Marmontel (1766), and Brébeuf (1795); in Italian, by Cristoforo Bocella (1804); in English, by Rowe (1718), and by May (1627), who also published in 1630 a continuation of the poem to the death of Julius Cæsar, which he afterwards translated into Latin verse (1640).

LUCAS, FREDERICK, many years editor of the *Tablet*, was born at Croydon, near Croydon, in Surrey, in 1812, and educated at the London University. In 1838 he was called to the bar, and the following year, although originally one of the Society of Friends, he became a member of the Roman Catholic Church. He soon afterwards established the Catholic newspaper called the *Tablet*, which in 1849 he transferred to Dublin. In 1852 he was elected M.P. for Meath, through the instrumentality of the Roman Catholic priesthood, of whom he was a zealous supporter, always advocating their right to interfere in political matters. But not being supported in these views by the Irish episcopate, in 1854 he travelled to Rome, in order to appeal to the pope against the decision of that body. But here his health broke down, and he was obliged to return to England, where he died in October, 1855.

LUCAYOS. [BAHAMAS.]

LUCCA, a province of central Italy, between latitude 43° 45' and 44° 7' N., longitude 10° 12' and 10° 42' E., is bounded N. by Modena, E. and S. by Tuscany, and W. by the sea. It is watered by the river Serchio, which rises in the Apennines, and enters the Mediterranean a few miles north of the Arno. Its area is 512 square miles. Its population in 1862 was 256,161. This territory is naturally divided into three regions: 1st, The mountainous districts among the Apennines, including the valley of the Lima, and the affluents of the Serchio; 2nd,

the valley of the Serchio, including the fine plain of Lucca, which is cultivated like a garden; 3rd, the flats near the sea, which are in part marshy, but produce good pasture for cattle. The whole province is considered one of the most fertile regions in Italy. Lucca was formerly an independent state, but was ceded to Tuscany in 1847, annexed to Sardinia in 1860, and is now incorporated in the kingdom of Italy. In the town of Lucca are, a lyceum with twenty-eight professors and a library of 16,000 volumes, two theological seminaries, a college, sixteen grammar-schools, and a great number of elementary schools.

Viareggio, with 6000 inhabitants, is, next to Lucca, the principal town of the province; it has a harbour defended by a fort, an export trade in statuary marble, and is much frequented in summer for sea-bathing.

LUCCA, the capital of the province, is situated in a rich plain watered by the Serchio, and surrounded by mountains: it is 12 miles from the sea, about 10 N.E. of Pisa, and contained, in 1861, 65,435 inhabitants. It is surrounded by ramparts, which are planted with trees, and form a very pleasant promenade. The town is well built, and well supplied with water; the streets are well paved and clean. Lucca, like most other Italian cities, is rich in churches, mostly built of Carrara marble; the cathedral, which belongs to the eleventh century, is adorned with good paintings, and with statues and monuments by the native sculptor Civitali. The archiepiscopal archives and those of the chapter contain a vast mass of historical documents, parchments, and MSS., some as old as the seventh century. The other remarkable churches of Lucca are those of San Frediano, San Francesco, and San Michele. The ducal palace (unfinished) is a vast building; it has a gallery of valuable paintings by the great masters, and a library of 25,000 volumes. The other remarkable structures are—the town-house, the aqueduct, on 459 arches, for the conveyance of water from Monte Pisano; theatre, many public fountains, the public library, and several of the mansions of the nobles. The Academy of Letters and Sciences of Lucca, instituted in 1817, which consists of thirty-six members, holds its meetings once a month, and has published several volumes of memoirs. Lucca also contains a seminary for noble ladies (founded by the sister of Napoleon I.), a botanic garden, and many benevolent institutions. It is the first place in Italy where silk was manufactured, and still has manufactures of this article, as well as of woollen fabrics and paper. An active trade is carried on in olive oil, which is esteemed the best in Italy. It is an archbishop's see. Under the Romans it was also made a *municipium*, and was often the head-quarters of Julius Cæsar. Here he made the famous alliance with Crassus and Pompey. In the twelfth century it became a free city. In 1805 Napoleon I. erected it into a principality for his sister Elizabeth's husband, Bacciochi. Lucca (Luca) is mentioned in ancient history as a town belonging to the Etruscans, after they had conquered the country between the Arno and the Macra and taken it from the Ligurians. It afterwards became a Roman colony, and there are still remains of a theatre and an amphitheatre.

Near the town are the reputed baths of Nero; and

11 miles to the north, in the valley of the Serchio, are the famous mineral baths of Lucca, the water from which is exported to all parts of Italy. Its temperature varies from 96° to 136° Fahr.

LUCERA. [CAPITANATA.]

LUCERN. [LUCERN.]

LUCERN. [MEDICAGO.]

LUCERNAL MICROSCOPE, an optical instrument invented by Mr. George Adams, an optician in London. It consists of a hollow pyramidal box, at the smaller extremity of which is a tube carrying the usual system of lenses for magnifying objects. At the larger end, which is towards the observer, there are two lenses in frames, their axes, as well as those of the small lenses at the opposite extremity, being coincident with the axis of the box; and between the exterior of the two lenses and the eye of the observer there is usually placed a plate of glass, rough-ground on one side, which serves as a screen to receive the rays of light proceeding from the object whose representation is to be viewed. The object is fixed in a small frame, as usual, and is placed in a groove made for the purpose immediately beyond the tube containing the system of lenses at the small end of the box. Instead of the plate of ground glass, a board painted white is frequently placed, to serve as a screen, at the distance of 6 or 8 feet from the instrument. Such a screen should have the form of a segment of a hollow sphere, the light being received on its concave surface.

An Argand lamp is usually placed beyond the object, with respect to the microscope, but for this the oxy-hydrogen light may be advantageously substituted: the light, after passing through a hemisphere of glass, is, when an opaque object is to be viewed, made to fall in a convergent state upon a small concave mirror, which is so inclined as to reflect the light back upon the object; and from the different points on the surface of the latter the pencils of rays proceed through the object-lenses and the box to the glass screen.

By the refraction of the light in passing through the lenses a highly-magnified image of the object is formed; and several persons may then place themselves so as to see the image on the screen at the same time; or by placing the eye at a small aperture in the produced axis of the instrument, one person may, with a pencil, draw on the glass, or on tracing-paper laid over it, the figure of the object, it being understood that by means of the proper adjusting screws the rays in each pencil are made to unite accurately in one point on the screen. The instrument is used by night or in a darkened room.

When the object to be viewed is transparent, the light is made to fall in a condensed state upon it, after having been transmitted through a convex lens, or two such; and from the object the rays proceed as before to the screen through the system of lenses which constitute the compound objective of the microscope, and through those at the opposite extremity of the box.

LUCERNARIA (Lat. *lucerna*, 'a lamp'), a genus of Polype, of the family *Lucernaidæ*, and order *Carnosi*. They resemble *Actinia*; but are of a softer substance. They fix themselves by a slender peduncle to sea-weeds and other bodies. As Cuvier describes them, the upper part expands like a parasol, and is

surrounded by numerous tentacula, arranged in bundles; and between these are eight cæca, proceeding from the stomach, and containing a red granulated matter. The species *L. quadricornis* has the edge in four forked branches with two bundles of tentacula in each. The other species, *L. auricula*, has the border octagonal, with a bundle of tentacula in each division. The annexed is a representation of the natural size.

Lucernaria auricula.

These *Lucernaria* feed upon any minute animals that may happen to come within the reach of their tentacula, which, when searching for food, are stretched out to their full extent; but as soon as any unfortunate creature comes in contact with them, they seize and at once carry it to the mouth. 'Although generally stationary,' says Mr. Couch, 'these creatures are able to swim with considerable rapidity, by alternately contracting and dilating the body. In moving about to short distances, as from place to place on the plant to which they are attached, they adopt the same plan as the *Hydra*, bending down their oral extremity until they can adhere by the tentacles, when the footstalk is loosened and thrown forward, and twirled about, till it meets with a place to suit it. It is then fixed, and the tentacula are loosened, and in this way they move from one spot to another. Sometimes they move like the *Actinæ*, by a gliding motion of the stalk.'

LUCERNINE (Lat. *lucerna*, 'a lamp'), a subfamily of the *Helicidae*, or Testaceous Snails, with discoid shells, and the aperture generally toothed; of which *lucerna* is the type.

LUCIA, ST. [ANTILLES; WEST INDIES.]

LUCIAN, a Greek writer, was born at Samósata, a city on the west bank of the Euphrates, in the Syrian province of Commagène. He was born about the latter end of Trajan's reign, lived under both the Antonines, and died in the reign of Aurelius Commodus, or shortly afterwards. His parents, who were in humble circumstances, placed him with his maternal uncle, a sculptor; but he soon quitted this trade, and applied himself to the study of the law. He afterwards practised at the bar in Syria and Greece; but not meeting with much success in this profession, settled in Gaul as a teacher of rhetoric, where he appears to have remained till he was about forty, when he gave up his profession, after having acquired considerable wealth. The greater part, if not all, of his dialogues appear to have been written after this time. During the remainder of his life he travelled about and visited successively Macedonia, Cappadocia, Paphlagonia, and Bithynia. The greater part of his time, however, was passed in Athens. Towards the latter part of his life he held a lucrative

public office in Egypt, which was bestowed upon him by the Emperor Commodus.

The dialogues of Lucian are written in pure and elegant Greek. He had great wit, and the flow of his language is easy and natural. He exposed fanaticism and imposture, the frauds of the priesthood, the folly and absurdity of the superstitious, and especially the solemn nonsense and the immoral lives of the philosophical charlatans of his age.

The best editions of Lucian's works are by Hemsterhuis, who only edited part of the first volume, and Reitz (4 vols. 8vo), by Lehmann (Leipzig, 9 vols. 8vo), and the edition published by the Bipont Society; the best translation of Lucian in German is by Wieland (6 vols. 8vo); in English, by Dr. Franklin, 1780, and by Tooke (London, 2 vols. 4to, 1820).

LUCIAN, SAINT, presbyter of Antioch, suffered martyrdom during the reign of Diocletian, in 312, and was buried at Helenópolis in Bithynia. He is frequently mentioned by ecclesiastical writers as a man of great learning and piety. His fame rests upon his profound and laborious study of the Scriptures, of parts of which he made many highly-prized versions.

LU'CIDA, a name formerly given to the brightest star in any constellation: thus we have *Lucida Hydræ*, *Lucida Lyreæ*, &c.

LUCIFER, bishop of Cagliari in Sardinia, is principally known in ecclesiastical history for refusing to hold any communion with the clergy who had, during the reign of Constantius, conformed to the Arian doctrines, although it had been determined in a synod at Alexandria, in 352, to receive again into the church all the Arian clergy who openly acknowledged their errors. Lucifer in consequence left the Catholic church, and his followers were called Luciferians. He died about the year 370.

LUCIFER MATCHES (Lat. *luciferus*, 'light-bearing'). Small slips of wood, the ends of which are dipped in melted sulphur or paraffin, and afterwards tipped with a composition of glue, phosphorus, and chlorate of potash, which ignites when smartly rubbed upon any rough substance.

They are sold in little boxes at a very cheap rate, and have become almost indispensable in domestic economy. The old tinder-box, the phosphorus bottle, the sulphurous match, and a variety of other chemical contrivances, have all given way to the simple congreve or lucifer match, the very perfection of utility and cheapness. Whether they ignite quietly, like congreves, or noisily, like lucifers, they all have the property of emitting instantaneous light simply by friction; and all have either phosphorus or chlorate of potash as one ingredient in the composition with which they are tipped. Humble and unimportant as these tiny bits of wood may appear in a commercial point of view, yet their production affords extensive employment to many thousands. Amongst the number of match manufacturers in London, we are told of one who cuts up several hundred large timber trees into splints for matches every year, and makes 10,000,000 matches per day. In this process of cutting, many forms of machinery are brought into operation. In some the wood is first cut into quadrangular blocks, which are operated upon by a long range of sharp parallel knives; and these cutting knives work with such amazing velocity, that from 30,000 to

40,000 splints can be cut up in a minute. These splints are then sold wholesale to the different match makers in the metropolis, and other large towns. Matches, however, as well as the little retail boxes themselves, are very liable to ignition, which is often fraught with great danger. To obviate this a new mode of preparing the combustible materials has been invented by Mr. Lundstrom of Jonkoping, Sweden, and patented in England by Messrs. Bryant & May, London. The peculiarity of these matches consists in the division of the combustible ingredients between the match and the friction paper, instead of their being amalgamated in the composition forming the match. Thus the phosphorus (in the amorphous state) is placed on the paper, and a minimum amount of glue and chlorate of potash is combined with the match. By this arrangement neither match nor friction paper individually takes fire from friction. It is only when the phosphorized paper and the match come into contact with each other that ignition takes place. Thus accident from casual explosion can never occur. The trade of match making was formerly exceedingly unhealthy, but improvements have been recently effected and the workshops placed under the operation of the Factory Act, in England. The trade has assumed enormous dimensions in England and Germany: immense quantities are exported from both countries. The quantity of lucifer wood imported into the United Kingdom in 1864 was 173,977 cubic feet, valued at 32,622*l*. The value of the matches exported from this country in the same year was 103,905*l*.

LUCILIUS, CAIUS, was born at Suessa Aurunca (*Sessa*), a town in the north-western part of Campania, B.C. 148. The time of his death is uncertain. Lucilius is said by Horace ('Sat.' i. 1, 61) to have been the first writer of Roman satire; by which he means that Lucilius was the first who constructed it on those principles of art which were considered in the time of Horace as essential requisites in a satiric poem. The satires of Lucilius were very popular even in the Augustan age. Besides his satires, in thirty books, Lucilius wrote a comedy entitled 'Nummularius,' epodes, and hymns, none of which are extant, with the exception of a few fragments from his satires, which were collected and published by Douza, Leyden, 1597.

LUCINA, in Conchology, the name given to a genus of conchiferous Mollusca, and the type of the family *Lucinidae*. The shell is orbicular in shape, and of a white colour. The umbones are depressed; the lunule distinct; the margins small or minutely crenulated. (See Plate, 'Conchology.') The animal has the mantle freely open below; the siphonal orifice simple; the mouth minute; the gills single on each side; and the foot, which is twice as long as the animal, is cylindrical, pointed, and slightly beeled at the base. There are about seventy species. Their geographical range is wide; they are found on the coast of Norway and of the West Indies and New Zealand. Two hundred species have been found fossil in the Upper Silurian.

LUCIUS I. II. III. [POPE.]

LUCKENWALDE. [BRANDENBURG.]

LUCKNOW, a city of British India, the capital of the province of Oude, stands on the right bank of the river Goomtee, in 26° 51' N. lat., and 80° 50' E. long. It became the residence of the court of the

king of Oude in 1775, after which it was considerably enlarged, and soon became one of the wealthiest cities of Hindustan.

Lucknow consists of three distinct quarters: the first, or oldest part, is made up of narrow and dirty streets, and is very populous. The second quarter consists of one handsome street, with a well built market-place in the centre, and with smaller streets branching from it at right angles. The greater part of the houses in this quarter were the property of the king, and were occupied by branches of his family or persons attached to the court. A space between this street and the river contains the royal palace and gardens. The remaining quarter of the city is built in a purely oriental style, and contains many splendid houses and religious edifices. The city has thus a most imposing external appearance. In some of its buildings Grecian architecture has been imitated; and many of the private palaces are filled with European furniture. The *Imambarah*, or mausoleum of Asoph-ad-Dowlah, is a fine building. Between the city and the decaying country seat, Constantia, is the Delkusha park, with an extensive menagerie. Since the mutiny Lucknow has been much improved. It has now a Christian church, an observatory, an hospital and dispensary, and a military cantonment of the British, four miles to the north-west of the city.

In 1857 the British garrison was long besieged by the rebels, but partially relieved by Sir Henry Havelock and General Outram, and completely by Lord Clyde. Here Havelock was attacked with cholera, which abruptly terminated his heroic career. The entire population of the city is estimated at 300,000. Many posts of usefulness and honour have recently been thrown open to the natives.

LUCON. [PHILIPPINE ISLANDS; VENDÉE.]

LUCRETIA. [BRUTUS, M. JUNIUS.]

LUCRETIVUS, with his full name TITUS LUCRETIVUS CARUS, was born B.C. 95, and died B.C. 52, in the forty-fourth year of his age. The poem of Lucretius entitled '*De Rerum Natura*' (*On the Nature of Things*), in six books, contains a development of the physical and ethical doctrines of Epicurus. [EPICURUS.] Notwithstanding the unpromising nature of his subject, there is no writer in whom the Latin language displays its majesty and stately grandeur so effectively as in Lucretius.

The best editions of Lucretius are by Lambinus, whose commentary is very useful, 1563, 1570; Havercamp, 1725; Wakefield, 1796-97; Eichstädt, 1801; and Forbiger, 1828. The translations most worthy of notice are, the English by Creech, 1714; and by Mason Good, with the Latin texts and notes in two vols. 4to, 1805; the English prose edition by the Rev. J. S. Watson, M.A. (London, Bohn's Classical Library, 1851); the French by Lagrange, with the Latin text, 1799; the German by Meinecke, 1795, and by Knebel, 1821; and the Italian by Marchetti, 1717, frequently reprinted. A good estimate of Lucretius and his poetry will be found in Professor Sellars' essay on '*The Roman Poets of the Republic*' (Edinburgh, 1863).

LUCRINE LAKE. [AVERNO.]

LUCULIA, a genus of the natural family of *Rubiaceæ*, sub-order *Cinchonaceæ*, tribe *Cinchoneæ*, and sub-tribe *Eucinchoneæ*, thus indicating the close affinity of this genus to that of the trees yielding

Peruvian bark, or true *Cinchonas*, in which indeed the only known species, *L. gratissima*, was placed by Dr. Wallich and figured in his '*Tent. Fl. Nepal.*' t. 21. It is found in great abundance on some of the other smaller hills in the Valley of Nepal. It delights in exposed and rather naked situations, blossoming, according to the situations where it is found, nearly the whole year round. As seen by Dr. Wallich, it attains a height of sixteen feet, but he was informed of its growing to a larger size. It has been introduced into and has flowered in this country; but from the nature of the climate where it is indigenous it is only suited to the green-houses of England.

LUCULLUS, LUCIUS LUCINIUS, descended from a distinguished Roman family, was born about B.C. 115, and served under Sulla in the Marsian war. Whilst Sulla was besieging Athens (B.C. 87), Lucullus was sent into Egypt and Africa to collect a fleet; and after the conclusion of the war with Mithridates, he was left in Asia to collect the money which Sulla had imposed upon the conquered states.

In B.C. 74 he was elected consul, and appointed to the command in the war against Mithridates. During the following eight years, and in a series of brilliant campaigns, he completely defeated Mithridates and his son-in-law Tigranes. Lucullus never appears to have been a favourite with his troops; and their disaffection was increased by the acts of Clodius, whose sister he had married. The popular party at home also attacked a general who had been the personal friend of Sulla, and who was known to be a powerful supporter of the nobility. They eventually carried a measure by which he was removed from the command, and succeeded by Pompey, B.C. 66. Lucullus, on his return to Rome, took no part in public affairs, and passed the remainder of his life in retirement. The immense fortune which he had amassed during his command in Asia he employed in the erection of magnificent villas, and he lived in a style of magnificence and luxury. He died about B.C. 57.

LUDLOW. [SHROPSHIRE.]

LUDLOW, EDMUND, was born at Maiden Bradley in Wiltshire, about the year 1620. His father was Sir Henry Ludlow, a considerable landed proprietor in that county, and its representative in the Long Parliament. Edmund Ludlow volunteered into Essex's army, and first engaged the king's forces at the battle of Edge Hill (1642.) He was one of the most active assistants in Colonel Pride's Purge, one of the foremost of the king's judges, and one of the most eager voters for the annihilation of the House of Peers. His independence rendered him obnoxious to Cromwell, who sent him to Ireland with a military command (1650). When Cromwell assumed the authority of protector, Ludlow loudly protested against his elevation, and if he had been in England might possibly have impeded it. Consistent in his advocacy of an equal commonwealth, he refused, when he left Ireland, to yield Cromwell an unqualified submission. He was regarded with great jealousy on account of this refusal, and security was required that he should not act in hostility to the government. When the king was restored Ludlow fled the country. In 1689 he returned to England; but an arrest was threatened, and he was compelled again to fly to Vevey, where he died in 1693, aged about seventy-three years.

His memoirs were first printed at Vevay, two volumes in 1698, and a third in the following year. (Ludlow's *Memoirs*.)

LUDOLPHUS, JOB (the Latinized form of his real name Leutholf), was born at Erfurt, the 15th June, 1624, and was educated at the University of Leyden, where he principally studied jurisprudence and the Oriental languages. During the latter part of his life he resided at Frankfort-on-the-Main, where he died on the 8th April, 1704.

Ludolph was one of the most eminent Oriental scholars of his age, and appears to have been the first European who acquired a knowledge of the Ethiopic language, which he learned with the assistance of a native of Abyssinia. Ludolph also paid great attention to the Amharic language, of which he published a dictionary and grammar in 1698. Among the most important of Ludolph's other works are a 'History of Æthiopia' in Latin, Frankfort, 1681, of which there is an English version.

LUFF, a nautical term: the order to the helmsman to put the tiller towards the lee side of the ship, in order to make her sail nearer to the wind. A ship is said to *spring her luff* when she obeys the helm. *Luff round*! is to throw the ship's head up in the wind. *Luff tackle*, a large tackle, not destined for any particular part of the vessel, but movable at pleasure.

LUGANO. [**TICINO.**]

LUGGER, a vessel which carries a lugsail on each of its masts, and occasionally a topsail. The lugsail is of a quadrilateral shape, and is bent, by the upper side, upon a straight yard, which is slung on the mast in an oblique position, one-third being to the windward and two-thirds to the leeward side of the mast. Luggers, in England, scarcely ever exceed large fishing vessels in size, but in the French navy ships as large as British schooners are often lugger-rigged. The form of the sail enables them to beat close to the wind.

LUG-WORM. [**ARENICOLA.**]

LUIGI, ANDRE'A DI, commonly called *L'Ingegno*, and sometimes, *Andrea d'Assisi*, was born at Assisi about the middle of the fifteenth century. He was a painter of some eminence, and appears to have assisted Perugino in his works in the Vatican.

LUINI or **LOVINI, BERNARDINO**, was born at Luino, on the Lago Maggiore, about the middle of the fifteenth century. He is believed to have been the pupil of Leonardo da Vinci. Many of his greatest works, in oil and in fresco, are still in a good state of preservation in the Ambrosian library at Milan, and in the gallery of the Brera at Milan. There are many easel pictures in oil by Luini, both in and out of Italy, in public and private collections. Luini was still living in 1530, but the date of his death is not known. He had two sons, Evangelista and Aurelio, who are both praised by Lomazzo, their contemporary.

LUKE, ST., the Evangelist. Respecting the birth and early life of this evangelist we have no certain information; of his later history we learn something from his own work, the 'Acts of the Apostles.' A considerable knowledge of the Greek language is displayed in his writings, especially in his introduction to his Gospel, which is written in elegant Greek. On the other hand, his language contains many Hebraisms, and he was evidently well acquainted

with the religious rites of the Jews, whose mode of computing time he follows. (Luke xxii. 1; Acts ii. 1; xii. 3, 4; xx. 6, 16, &c.) Hence it has been much disputed whether he was a Jew or a Gentile before he embraced Christianity. It was a tradition current in Jerome's time, that Luke was a Greek by birth, but became a proselyte to Judaism early in life. The general belief is that he was by descent a Hellenistic Jew, and that he was born at Antioch. From Col. iv. 14, and from the testimony of Eusebius, Jerome, and other early writers, it appears that Luke was a physician.

The first distinct mention of Luke in the New Testament is in Acts xvi. 10, 11, where, in relating the vision which Paul saw at Troas, the writer suddenly begins to use the first person plural, whence it is inferred that Luke here joined the apostle (about A.D. 53), whom he accompanied to Philippi (ver. 12). He seems to have remained at Philippi during Paul's journey to Athens and Corinth; for he drops the first person at ver. 17, and does not resume it till he relates Paul's return to Philippi (xx. 5, 6). From this time it appears from the Acts that Luke was Paul's constant companion till his arrival at Rome (about A.D. 61 or 63), where he remained with the apostle for some time, probably during Paul's first imprisonment. He is mentioned more than once in Paul's epistles, written during this period. (Col. iv. 14; 2 Tim. iv. 2; Philem. v. 24.) Respecting the end of Luke's life, the tradition is, that after Paul's liberation from his first imprisonment, he retired to Achaia, where he resided some few years, wrote his Gospel and the Acts of the Apostles, and died at an advanced age (some say eighty, others eighty-four years), probably by a natural death.

LUKE, ST., THE GOSPEL OF, is a narrative of the life of Jesus Christ written by the evangelist, and one of the canonical books of the New Testament. Its most probable date is about A.D. 63 or 64. It is closely connected with the Acts of the Apostles, and was probably written not long before that book. (Acts, i. 1.) Some writers place it in A.D. 53. Theophylact asserts that it was written fifteen years after Christ's ascension. The common tradition is that it was written in Greece; Jerome says in Achaia and Boeotia.

Like the Acts of the Apostles, this Gospel is dedicated to Theophilus. The conjectures of critics respecting this personage are as numerous as is usual on such points; the conclusion at which most arrive is that he was a converted Gentile, living without the bounds of Palestine. This dedication, the testimony of early writers, and some marks in the work itself, such as the explanation given of matters exclusively Jewish, prove that the Gospel was designed for the benefit of Gentile converts.

LULLY, RAYMUND, surnamed the Enlightened Doctor, an enthusiastic and remarkable character of the thirteenth century, was born at Palma, in the island of Majorca, in 1234. In early life he followed his paternal profession of arms in the service of the king of Arragon, and abandoned himself to all the licence of a soldier's life. Passing from one extreme to another, Lully subsequently retired to a desert, where he pursued a life of solitude and rigorous asceticism. Here he pretended to have had visions, and, among others, a manifestation of Christ on the

cross, who called him to his service and the conversion of the Mohammedans. He accordingly divided all his property among the poor; and in his thirtieth year he began to prepare himself, by diligent study, for the labours and duties of a missionary. Learning Arabic from a slave, he read in that language several philosophical works, the perusal of which, in all probability, suggested those new views of grammar and dialectic by means of which he hoped to reform science, and thereby the world itself. Full of this idea, he had a second vision of the Saviour in the semblance of a fiery seraph, by whom he was expressly enjoined to commit to writing and to publish the treatise to which he himself gave the name of 'Ars Lullia,' but which his followers and admirers dignified by the title of the 'Great Art' (Ars Magna). Having besought James king of Aragon to establish a monastery in Majorca for the education of thirteen monks in the Arabic language and the duties of missionaries, he went to Rome to seek the countenance of Pope Honorius IV. for similar institutions and his own mission. Receiving, however, little encouragement, he visited Paris and Genoa with the same design, and with as little success. From Genoa he crossed to Africa, where he was in danger of losing his life in consequence of his dispute with a Mohammedan whom he sought to convert, but was saved by the intercession of an Arabian mufti, on the condition of quitting Africa for ever. This promise, however, he subsequently considered not to be binding; for, after revisiting Italy, and in vain seeking to excite sympathy and co-operation in his designs, he reassumed, unassisted, his enthusiastic enterprise. Proceeding first to Cyprus, and thence to Africa, he was nearly stoned to death, and, when cast into prison, owed his liberty to the generosity of some Genoese merchants. Upon his return to Europe Lully visited its principal cities, preaching the necessity of a crusade for the recovery of the Holy Land, a plan of which he laid before Pope Clement V., by whom it was received with little or no favour. Unchecked, however, by so many disappointments, and with the ardour of his enthusiasm still unabated, Lully returned a third time to Africa, where his zeal for conversion entailed upon him dreadful torments, from which he was a second time rescued by the generosity of the Genoese. The sufferings, however, to which he had been exposed were so great, that Lully died on his passage home, within sight of his native country, in the year 1315.

LULLY (or LULLI), JEAN BAPTISTE, the father of French dramatic music, was the son of a miller, and born at Florence in 1633. Having attracted the notice of the Chevalier Guise, he was by that nobleman recommended to Mademoiselle de Montpensier, niece of Louise XIV., as a page, and sent to Paris in his fourteenth year. Not being prepossessing in person, he was sent into the kitchen, but his musical talents soon commanded the notice of the king, and then he rose quickly in public estimation. When the Académie Royale de Musique was founded, Lully was placed at its head; and his success in this capacity was so great, that he realised a handsome fortune, and was raised to the situation of Secrétaire du Roi.

On the recovery of Louis from a severe operation, Lully composed a 'Te Deum,' and during its re-

hearsal, while beating the time to the band with his cane, he struck his foot a violent blow, and, having placed himself in the hands of a quack, his life paid the forfeit of his credulity. He died in Paris, in 1687.

LUMBAGO. [RHEUMATISM.]

LUMBRICUS, Earth-worms, a genus belonging to Cuvier's third order of *Annelids*, and to the first family (*Abranches Sétigères*) of that order. In recent classification it is ranked as a genus under the order *Terricolæ*, class *Annelida*.

The common Earth-worm (*L. terrestris*) is the type of the order. They are for the most part nocturnal in their habits, seldom venturing from their holes during the day. Worms are hermaphrodite and very prolific. Air for the oxygenation of the blood is taken in by pores on the sides. A series of microscopic hooks lie on the belly.

The Earth-worm is not only of great service to the agriculturist in loosening the earth, and rendering it permeable by air and water, but is also a most active agent in adding to the depth of the soil, and in covering comparatively barren tracts with a superficial layer of good mould. See a valuable paper 'On the Formation of Mould by means of the Earth-worm,' read before the Geol. Soc. London, by C. Darwin, Esq., F.G.S. It is probable that every particle of earth in old pasture land has passed through the intestines of worms, and hence in some sense the term 'animal mould' would be more appropriate than 'vegetable mould.' [ANNELEIDA.]

LUMINOSITY OF ORGANIC BEINGS. Recent observations have proved that various organic beings, both animal and vegetable, are endowed with a peculiar faculty of giving forth light. Every housewife will have noticed this circumstance in the case of dead mackerels and herrings, where it arises from a species of slime or organic matter collected on the outer surface of the fish. In the common mollusc, the *Pholas*, the property is singularly powerful, a single specimen rendering seven ounces of milk so luminous as to light up the faces of individuals. It is also found in the *Noctiluca miliaris*, and in the *Pyrosoma Atlantica*—the latter occurring in such myriads that the ocean is occasionally illuminated for miles with a brilliant phosphorescent glow. In polypes, rhizopoda, echinoderms, infusoria, annelides, medusæ, and the like, luminosity exists, as well as in several phanerogamic plants—the nasturtium and marigold, for instance; in certain genera of the Coleoptera, as in the glow-worm and fire-fly; and of the Hemiptera, as the lantern-fly.

LUMPERS. Labourers employed to load and unload merchant ships when in harbour.

LUMP-SUCKER. [DISCOBOLI.]

LUNACY. The subject of Lunacy, treated from a medical point of view, will be found in the article INSANITY. Unsoundness of mind is perhaps the most accurate definition of the present legal meaning of lunacy. Formerly a legal distinction was made between lunatics and idiots: a lunatic was one who has had understanding, but has lost the use of his reason; and an idiot, one who has had no understanding from his nativity. The distinction between these two classes of persons of unsound mind also produced some important differences in the management of their property, which have now fallen into disuse. Strictly speaking, perhaps, a lunatic is one who has

lucid intervals; but this distinction may also at the present day be disregarded.

Persons of unsound mind may inherit or succeed to land or personal property either by representation, devise, or bequest, but they cannot be executors or administrators, or make a will, or bind themselves by contract. A person of unsound mind, though he afterwards be restored to reason, is not permitted to allege his own insanity in order to make his own act void; for no man is allowed to plead his own disability (13 Vesey, 590), unless he has been imposed upon in consequence of his mental incapacity (2 Carr. & P., 178; 3 Carr. & P., 1, 30); and an action will lie against a lunatic for the supply of necessities suitable to his station. Acts done during a lucid interval are valid; but the burden of proving that, at the time when the act was done, the party was sane and conscious of his proceedings, lies upon the person asserting this fact. The marriage of a person of unsound mind, except it be solemnized during a lucid interval, is void.

As a general rule, it may be laid down, that where unsoundness of mind, of such a nature as to render the party incompetent to exercise any self-control, is established, criminal punishment will not be inflicted; but that he will be kept in safe custody during the pleasure of the Crown (39 and 40 Geo. III. c. 94, and 1 & 2 Vict. c. 14). On the subject of criminal responsibility, and what constitutes unsoundness of mind in a legal point of view, the reader is referred to the various treatises on medical jurisprudence, particularly to that by Dr. Ray, published at Boston, in the United States: and also generally to Dr. Haslam's 'Observations on Madness and Melancholy,' 'Medical Jurisprudence as it relates to Insanity,' 'Illustrations of Madness,' and his other works. Dr. Forbes Winslow on 'The Plea of Insanity in Criminal Cases' is a valuable book.

In an inquisition of lunacy the question to be decided is, not whether the individual be actually of sound mind, though a jury on an inquisition held under a commission of lunacy must express their opinion or finding in the form that the alleged lunatic is of unsound mind ('In re Holmes,' 1 Russell, 182); but, though such must be the finding in order to make a man legally a lunatic, the real question is, whether or not the departure from the state of sanity be of such a nature as to justify the confinement of the individual, and the imposition of restraint upon him as regards the disposal of his property. In all such inquiries it should be kept in mind that insanity varies infinitely in its forms and degrees. Persons may be of weak mind and eccentric, and even be the subjects of delusions on certain subjects, and yet both inoffensive and capable of managing pecuniary matters. The individual's natural character should be taken into consideration as accounting for eccentricities of manner and temper, and his education in estimating his ignorance and apparent want of intellect; and lastly, due allowance must be made for the irritation and excitement produced in a mind, perhaps naturally weak, by the inquiry itself, and the attempt to deprive a man of his liberty and the management of his property.

A lunatic is responsible for acts committed during 'lucid intervals,' a term by which is understood, however, not mere remissions of the violence of the

disease, but periods during which the mind resumes its perfectly sane condition. In forming an opinion concerning such lucid intervals, the absence of the signs of insanity must have considerable duration before it can be concluded that the mind is perfectly sane; for lunatics, when apparently convalescent, are subject to sudden and violent paroxysms.

One of the most difficult points to be determined is with regard to the mental capacity of old persons, in whom the mind is impaired. The decay of intellect in old age is first manifested in the loss of memory of persons, things, and dates, and particularly with respect to recent impressions. But it is not the mere liability to forget names, and such matters, which will render the will of an old person invalid; it should be shown that in conversation about his affairs, and his friends and relations, he did not evince sufficient knowledge to dispose of his property with sound judgment. Many old men appear stupid and forgetful; but when their attention is fairly fixed on their property, business, and family affairs, they understand them perfectly, and display sagacity in their remarks.

The care and custody of idiots and lunatics form a branch of the royal prerogative, and were formerly administered by the king himself. Since the dissolution of the Court of Wards, the lord-chancellor has been specially appointed to exercise this power. The method of proving a person to be of unsound mind, for the purpose of depriving him of the control of his property, and where the circumstances require it, providing for the safe custody of his person, is by the inquisition of a jury, summoned under a commission granted by the lord-chancellor. If the fact of lunacy be established, the care of the lunatic is committed to some fit person, and the care of his estate either to the same or to some other fit person.

The following acts have made alterations in the proceedings under commissions of lunacy.

An Act of the 3 & 4 Will. IV. c. 36, entitled 'An Act to diminish the Inconveniences and Expenses of Commissions in the nature of writs De Lunatico Inquirendo; and to provide for the better care and treatment of idiots, lunatics, and persons of unsound mind, found such by Inquisition.'

An Act of the 5 & 6 Vict. c. 84, entitled 'An Act to alter and amend the practice and course of proceeding under commissions in the nature of writs De Lunatico Inquirendo.' The first section empowers the lord-chancellor to appoint two sergeants or barristers-at-law, to be called 'The Commissioners in Lunacy,' and enacts that in future all commissions in the nature of writs De Lunatico Inquirendo shall be directed to such Commissioners, and that such Commissioners shall jointly and severally have and execute all the powers, duties, and authorities now had and executed by commissioners named in commissions in the nature of writs De Lunatico Inquirendo.

By the 8 & 9 Vict. c. 100, s. 2, the two commissioners of lunacy are henceforth to be called Masters in Lunacy, and take the same rank and precedence as the masters in ordinary of the High Court of Chancery. Some other regulations as to the duties of the masters in lunacy are contained in 8 & 9 Vict. c. 100, s. 95-98. The other sections of the Act 5 & 6 Vict. c. 84, make regulations as to fees and other matters, for which the Act must be consulted.

The term lunatic is only properly applied to a person who is found to be a lunatic by the verdict of a jury under an inquisition. But the term lunatic is also applied to those who, being considered lunatics, are confined in lunatic asylums or hospitals, and also to any single patient who is boarded or lodged for pay as a lunatic in a house not licensed; and also to any person who is under the care of any person who receives or takes the charge of such one lunatic only, and derives no profit from the charge.

Extensive alterations were introduced into the law and practice in lunacy by the Act of 1855, and the orders thereunder. Of these we name the principal:—A general commission has been issued to the masters in lunacy in lieu of the special commission formerly issued in each case. Juries are dispensed with, unless in particular cases it be found important to call them. The inquiry as to the state of mind is, except under special circumstances, not carried back, but limited to the present time. All matters affecting the person and property of the lunatic may, after the inquisition, be proceeded on before the masters without any special order of the lord chancellor for the purpose; and the provisions for insuring through the visitors and masters the proper care and treatment of the lunatic are made more comprehensive.

The following Acts contain amendments: 18 & 19 Vict. c. 13; 25 & 26 Vict. c. 86. This Act provides that every lunatic shall be visited by the proper officers at least four times a year. And the 26 & 27 Vict. c. 110. The chief amendments comprised in this Act are—That the inquiry as to the state of mind shall be confined to the question whether the person is at the time of inquiry of sound mind, and no evidence as to anything done or said by such person, or as to his demeanour more than two years before the time of inquiry, shall be received as evidence of insanity.

That upon a trial before a jury the person himself shall be examined before the taking of any evidence, and at the close of the proceedings; and such examination shall be taken in public or private as the judge may direct. The alleged lunatic may demand a jury.

The lord chancellor is given power to apply in certain cases the property of a lunatic for such lunatic's benefit.

The Act contains other regulations as to the practice in lunacy not necessary to insert here.

The law of Scotland recognizes two distinct kinds of mental incapacity—fatuity or idiocy, and furiosity or insanity. Persons labouring under mental disease in either form are protected by law, both as regards their persons and estates. But the amount and nature of the protection accorded to them varies, according as their incapacity is total and permanent, or partial and intermittent.

Total Incapacity.—When the incapacity is of this kind, the person labouring under it is placed under guardianship by the Supreme Court. But the necessity for this step must, in all cases where there is resistance or any conflicting right, be established by the verdict of a jury, proceeding upon a *briefe* of Chancery obtained at the instance of the next of kin of the insane person, and directed to the judge-ordinary of the territory in which the person to be cognosed resides. The *briefe* is directed to ascer-

tain either his fatuity or furiosity, as the case may be; and the jury, from the evidence of the witnesses and examination of the person himself, must return a verdict as to his present condition of mind, the date at which the malady commenced, and whether or not there are lucid intervals in his disease. They must also ascertain who is his nearest male cognate, upon which his curatory may be conferred. The *briefe* is then returned to Chancery and becomes the warrant upon which to apply for letters of curatory from the Supreme Court. Where the necessity for a cognition does not exist, the court will, on petition of the lunatic's next of kin, appoint a guardian to him *ex nobili officio*. Total incapacity may further be established in relation to any particular deed or transaction by an action of reduction. This may be brought after the death of the granter of the deed sought to be reduced, and in this action it is not necessary to prove the time at which the insanity commenced, but only that it existed at the date of the deed in question. When insanity exists attended with lucid intervals, the general rule of law is that acts done during these intervals are valid.

Partial Incapacity.—In all cases of *imbecility* arising either from age, from facility of temper, or from organic affection, by which a person is incapacitated from attending to his own affairs, the court will on cause shown appoint either a judicial factor or *curator bonis* to undertake their management. The same rule holds with regard to *temporary incapacity*, occasional delirium, absence abroad, or by the interval before a cognition can take place.

Interdiction.—In order to protect persons of a profuse or prodigal disposition, or of a weak and facile nature, from the effects of their own improvidence, the law has provided the remedy of *interdiction*, by which such persons are disabled from burdening or alienating any part of their heritable estate, without the consent of certain persons who are called their interdictors. Interdiction is either judicial or voluntary, that is, it may proceed either upon a judgment of court finding and declaring the person to be of a weak and facile disposition, or by a bond granted by the person himself in which he expresses his consciousness of facility, and lays himself under an obligation to grant no deed without the consent of his interdictors. Letters of publication then follow thereon, and are executed by a messenger-at-arms at the market-cross of the jurisdiction where the prodigal resides, and the interdiction is then recorded in the Register of Inhibitions of the county where any of his lands lie.

Plea of Insanity in Criminal Cases.—In criminal cases insanity may be pleaded either in bar of punishment, or in bar of trial. The old test of insanity—that the pannel did not know the distinction between right and wrong—is now completely exploded. Wherever there is clear proof of the existence of mental disease clouding and dethroning the mind, the defence of insanity will be admitted.

By the Roman law persons of unsound mind might be deprived of the management of their property and persons on application to the *pretor* by their next of kin. This regulation dates back to the time of the Twelve Tables. The curatory was given to the nearest cognate of the lunatic, and when there were none, the *pretor* or the *præses* in the provinces

named on. (Dig. 27, 10, 1.) An insane person could not make a will or exercise any other civil right so long as his malady lasted. When it ceased, the curatory fell at once. By the code of the Twelve Tables prodigals were placed under the same restraints as lunatics with regard to the management of their affairs.

LUNAR CAUSTIC, a term applied to the fused nitrate of silver, when produced in small cylindrical cakes. It bears a whitish-striated appearance, decomposing and turning black when exposed to the air. In surgery it is frequently employed, sometimes to cauterize warts, ulceration of the mucous membrane of the throat, and the 'proud flesh' which grows up about wounds and ulcers. It is also used to stimulate the action of lethargic ulcers as well as ophthalmic affections, and many varieties of skin disease.

LUNAR OBSERVATION generally means an observation of the moon's distance from a star, for the purpose of finding the longitude.

LUNAR THEORY. By the theory of a planet is meant the deduction of its motion from the law of gravitation.

LUNATIC ASYLUMS. The subject of insanity and asylums for the insane has of late years occupied a very large share of public attention, particularly as an opinion has prevailed that insanity is on the increase in this kingdom beyond the ratio of population. For reasons which will be presently stated it is, however, believed that this increase is more apparent than real.

Two acts passed in 1845 (8 & 9 Vict. caps. 100 and 126) placed the powers vested in the Commissioners in Lunacy on an entirely new footing, and in many respects modified the constitution of asylums. The first Act appoints six commissioners, three of whom are physicians, and three barristers, with salaries; and five other commissioners, who act gratuitously. The rule that none of these shall be connected with any asylum is continued. Licenses to receive lunatic patients are granted by these commissioners at each of their quarterly meetings. No license is to remain in force more than thirteen months, and the notice of a wish to renew must give the number of patients then confined. The jurisdiction of the commissioners extends to the whole of London and Middlesex and Southwark, and to all places within seven miles of London, Westminster, and Southwark: in the country the licenses are to be granted by the justices of the peace in quarter session, who are bound to appoint three of their number, together with one physician, surgeon, or apothecary, as visitors of the asylums licensed by them. Strict regulations are enforced for the reception of patients; it is required that every person not being a pauper, received as insane, shall be certified to be so by two physicians or surgeons, who shall visit such patient separately, and shall have no interest in the asylum in which such patient is to be confined; and certain entries of these particulars are to be kept at each asylum. For a pauper the certificate of one medical man and the order of two justices is required.

Penalties are fixed for neglecting these rules, or those which direct notice to be given of every admission, death, discharge, or escape. Houses having

100 or more patients are to have a resident medical attendant, and those of smaller size are to be visited by a medical attendant at defined periods, according to their size. Every house within the immediate jurisdiction of the commissioners shall be visited by them at least four times a year, and every other house at least twice in every year. Similar powers are given to the visitors in the country.

The commissioners are to present an annual report to the lord-chancellor of the state of the different asylums visited by them, which report shall be laid before Parliament.

An important alteration is made in the law concerning the care of single patients. Orders and medical certificates must in future be procured for the care of one patient similar to those used for the admission of patients into licensed houses; and copies of these documents are to be privately sent to and registered by the secretary to the commissioners. This Act only extends to England and Wales, and it does not affect Bethlehem Hospital, London. The persons appointed to hold commissions 'De Lunatico Inquirendo,' heretofore styled commissioners, are in future to be termed 'Masters in Lunacy.'

The second Act, which repealed 9 Geo. IV. c. 40, and which is now repealed by 16 & 17 Vict. c. 97, relates to the regulation of lunatic asylums for counties and boroughs, and the maintenance and care of pauper lunatics, and gives to the commissioners a greater power over these institutions. The justices of every county and borough are now to be compelled to erect or join in the erection of an asylum when none such already exists; and all proposals, agreements, and plans, and the rules and regulations of each asylum, are to be submitted to the commissioners, and they and all contracts and estimates approved by the secretary of state. Contracts for the care of insane persons in licensed houses do not exempt any county or borough from the obligation of providing an asylum. This Act extends only to England and Wales, and does not apply to Bethlehem Hospital. Medical men signing false certificates are made guilty of a misdemeanor; and certain penalties are inflicted on officers and servants illtreating lunatics.

The justices of the peace are to appoint a visiting committee to whom everything is to be submitted. The visitors have to grant retiring allowances to the officers not exceeding two-thirds of their salaries; to draw up rules for the regulation of the asylum, the same to be submitted to the secretary of state; to fix weekly rates for the maintenance of each pauper lunatic; to appoint a chaplain, medical officer, clerk, and treasurer; and to audit the accounts.

Every pauper lunatic not in an asylum or licensed house is to be visited by the medical officer of the union once a quarter.

The Act contains provision as to the care of lunatics wandering at large, and also the certificate under which one is to be received into an asylum. It provides for raising the funds for the maintenance of the asylum; enacts the penalties for breaches of the Act; and contains ample directions as to the disposal of the lunatic's property.

The Act has been amended in some points not here necessary to mention by the 18 & 19 Vict. c.

105; 19 & 20 Vict. c. 87; 25 & 26 Vict. c. 111; 26 & 27 Vict. c. 110.

The leading Act regulating the care and treatment of lunatics in Scotland is the Act 20 & 21 Vict. c. 71, 1857. But various amendments have been made thereon by 21 & 22 Vict. c. 89; 25 & 26 Vict. c. 54; 27 & 28 Vict. c. 59. A bill is presently before Parliament (Lunacy (Scotland) Act, 1866) for the purpose of still further amending the law on the subject.

Management of Lunatic Asylums.—For a very long period it was unfortunately taken for granted, both in England and in other countries, that insanity was incurable, and coercion and confinement were the chief appliances used in all cases where any restraint appeared necessary. When they were supposed to be harmless, lunatics and idiots were suffered to wander about the country, trusting to precarious charity, and subjected to occasional whippings. The worst cases only were admitted to the asylums which were so sparingly provided, and the treatment of the inmates in these institutions was often brutal in the extreme. In the old Bethlehem Hospital, for instance, the patients were made a show of like wild beasts, and they were often excited to rage to make the exhibition more stimulating. Such scenes were not peculiar to England, but could be paralleled in almost every country in Europe. At length in 1792, a benevolent Frenchman, named Pinel, made the first systematic attempt to restore the insane to a position among human beings. His plan, which was designated the non-restraint system, was at first ridiculed and scoffed at; but by dint of great perseverance and continuous personal exertions, he at length induced the governors of the Bicêtre, a hospital near Paris, to permit him to unchain some of the inmates, and so salutary were the effects of his experiment, even on the first day, that the old plan was soon entirely abolished and a course of milder treatment pursued. England is proverbially slow in adopting improvements, and for twenty-three years after the chains had been removed from the inmates of the Bicêtre, the old mode of treatment continued in full force in this country. It is true that nearly simultaneously with the early measures of Pinel, and, as is believed, without any knowledge of them, Mr. William Tuke, a Quaker, conceived the plan of founding a hospital for the treatment of the insane, upon principles more enlightened and humane than those which then prevailed; and his idea was carried out by the construction of 'The Friend's Retreat' for the insane, at York, which was opened in 1796.

But it was not till the year 1813 that the English Government took up the matter. In that year a committee of inquiry was appointed to investigate the state of the York asylum—special attention having been directed to this particular institution in consequence of the success of the Friend's establishment in that city—and the horrors which were then divulged could scarcely be credited if they were not well attested by facts. The state of the patients at Bethlehem was next inquired into, and they were found to be even worse treated than those at York. From this time a gradual, but very slow, improvement in the condition of the insane may be noticed. Chains were removed and leather restraints of much milder kinds substituted, and more care was

given to the warming and clothing of the patients. Between 1815 and 1830 many large asylums were opened in England. They were built on the then most approved principles, and in all of them the milder methods of treatment were adopted. Things continued to gradually improve, and in 1839 Mr. Hill, the surgeon of the Lincoln asylum, published a work in which he advanced the following proposition as a principle:—'In a properly constructed building, with a sufficient number of suitable attendants, restraint is *never necessary, never justifiable, and always injurious, in all cases of lunacy whatever.*' The doctrine was at first declared, even by those in favour of the milder treatment, to be too decided, and likely to produce a bad effect; but fortunately the lapse of thirty years has proved its perfect truth, by its adoption in all the most important asylums in the kingdom.

The following noteworthy table, compiled from the records of the Lincoln Asylum, by Mr. Hill, well illustrates not only the extent to which mechanical restraint was once employed, but the statistical history of its reduction.

Year.	Total number in the house.	Total number restrained.	Total number of instances of restraint.	Total number of hours under restraint.
1829, .	72	39	1,727	20,424
1830, .	92	54	2,364	27,113 $\frac{3}{4}$
1831, .	70	40	1,004	10,830
1832, .	81	55	1,401	15,671 $\frac{1}{2}$
1833, .	87	44	1,109	12,003 $\frac{1}{2}$
1834, .	109	45	647	6,597
1835, .	108	28	323	2,874
1836, .	115	12	39	334
1837, .	130	2	3	28

In connection with the foregoing, it must be mentioned that the entries of the visitors and the reports of the physicians alike agree in describing the condition of the patients as much improved, the quiet of the house increased, and the number of accidents and suicides materially reduced.

In their general report, the Commissioners of the Census of the United Kingdom for 1861, state that 'The laws for the protection of the person and property of lunatics in England continue to be carried out with vigour and success. By a system of inspection and control, both of public and private establishments for the reception of the insane, the number of patients is restricted within the limits of the accommodation afforded, and salutary regulations are enforced. Every care which experience can suggest is bestowed on the internal arrangements and organization of the larger establishments, and the more recently constructed asylums are regarded as models of their kind.'

The treatment of insanity, as pursued at the present day, is properly divided into two parts. One of these might be termed the *direct*, the other the *indirect*, but they are generally called the *medical* and the *moral* treatment. The medical treatment

consists in the use of such medicines as, in each particular case, will be likely to restore the body to a healthy condition. This treatment, as a method, has undergone a radical change within the last fifty—mostly within the last thirty—years. Formerly, based upon the hypothesis that insanity was a disease of strength, or of active inflammation, it chiefly consisted in the liberal employment of blisters, purgatives, cupping, and blood-letting. Now, founded upon the well-supported theory that the disorder originates in debility, its principal remedies are stimulants and tonics. The success of the present method demonstrates not only the excellence of the practice, but the truth of the theory.

The moral treatment includes the exercise of a mild but firm directive and disciplinary power over the actions of the patient, by which he is gradually restored to healthful habits and wholesome self-restraint, and the attempt to win him from the vagaries of his delusions to those mental and manual pursuits which give solidity, strength, and activity to the normal mind. The means adopted for the attainment of these ends are, the regular hours of hospital life, appropriate manual labour, walking, athletic and other games, attendance upon religious services, reading and other literary pursuits, lectures upon scientific and miscellaneous subjects, dramas, concerts, balls, and other recreations, entertainments, and amusements. In the method of moral treatment the change has been no less than in medical treatment.

This change may be comprehended in two brief generic statements: first, the almost absolute disuse of mechanical appliances for bodily restraint: and secondly, the introduction of the conveniences, comforts, and to some extent the luxuries that appertain to civilized life, into the apartments of the patients, and to all parts of the hospital establishments where such means will benefit them. By this gentle and judicious treatment a large increase has taken place in the number of cases of insanity which have been cured, especially in the early stages of the disease.

So many public asylums have been built that there has been a very great variety of construction. The chief requisites insisted on by the Commissioners are light, ventilation, proper means of warming, convenience and cheerfulness in the furniture, and, above all, ample means for out-door exercise. The only doubtful part of the arrangement is the dormitories, some good authorities preferring open wards, as admitting the most effective superintendence at night; others advocating separate sleeping apartments, as being less likely to admit of any one patient disturbing another. Both plans have been adopted; and the results do not appear to differ materially.

A great improvement has taken place in the class of persons appointed as attendants, or, according to the old phraseology, keepers. That all such persons should possess benevolence and intelligence is essential to the effective working of a humane and enlightened system; and they should be liberally paid. The proportion of attendants to patients in the different English public asylums varies from one to ten, to one to twenty; the former does not seem too much, and is far less than that in all well-managed private asylums. No ward, however small, should have less than two attendants, in order that it should

never be left without one: this is enforced by the rules of several asylums, and is most essential whenever a night attendance is adopted. In some asylums this is endeavoured to be effected by making the day attendants undertake night duty in turns; but this is taxing their physical powers too severely, even when they are released from duty for half the succeeding day.

The private asylums for the wealthy classes are assimilated in their arrangements to ordinary dwelling-houses, and it has been proposed to place the least affected of the indigent in cottages near the public asylums, with a view to their more speedy recovery.

Before the close of the eighteenth century, German students in the medical school of Paris had carried home the new theory and practice of Pinel, and had begun that work of reformatory regeneration of the institutions for the insane in their native land, which, though small at its beginning and repressed by hindrances similar to those already alluded to, has since been prosecuted with perhaps no less vigour or success than in France or England.

The spirit of the enterprise crossed the Atlantic more slowly than it traversed the boundaries of the German states, but the success of the 'Friend's Retreat' at York having become known on the other side of the Atlantic, the Society of Friends, in Pennsylvania, erected a similar institution near that city. Shortly afterwards the eminent philanthropist, Miss D. L. Dix, began a series of benevolent and beneficent labours, to which female biography, throughout the history of the world, probably exhibits no equal. Beginning in Massachusetts, and subsequently proceeding to other states, she traversed the counties and townships within their several jurisdictions, visited all the public receptacles for the insane, together with all the private hovels, dens, garrets, and cellars for solitary maniacs, to which access could be gained. She stimulated individuals to exertions and contributions in the cause, and in memorials to legislatures and by appeals to Congress, called upon the governments to extend the assistance of the commonwealth to this class of suffering people.

There are now rather more than fifty public asylums in America. A large proportion of them will not suffer in comparison with the better class of similar institutions in Great Britain, France, and Germany. It is believed that, in executive administration, they are governed with prudence, benevolence, and kindness; that their officers are generally earnest labourers, emulous of improvement; and that the unfortunate insane may be committed to them in full confidence of immunity from cruelty or abuse.

Besides the public institutions, a few private establishments for the treatment of the insane have been opened in the United States, in the course of the last forty years. Although some of those which have been discontinued were directed by able and humane men, and several others still in operation are considerably patronized and well conducted by men of high character, yet a consciousness of the undeniable tendency to abuse involved in a purely private pecuniary enterprise of this kind, has operated to discourage their multiplication and prosperity.

America has a journal devoted entirely to insanity, the first number of which was issued in July, 1844.

Intended not alone for the benefit of professional readers, but also for the dissemination of more accurate views of insanity among the people, its editor endeavoured to adapt its contents to the attainment of this twofold object. The journal is still continued, but has assumed a more purely scientific and professional character, and has done great service in the cause to which it is devoted.

Statistics of Lunacy.—At the date of the census of 1861, there were in the principal civil lunatic asylums and establishments for the reception of the insane in England and Wales 24,345 persons—viz., 11,249 males and 13,096 females. This number is defective as regards the total amount of persons labouring under aberration of mind, as it not only excludes some lunatics in licensed houses, where a very small number are received, and lunatics at large or in the custody of their relatives, but also the patients in military and naval asylums, as well as lunatic paupers in workhouses, and a few lunatics in jails, who are not distinguished from other inmates in the returns from those institutions. The number thus understated furnishes a ratio of one lunatic patient in an asylum to every 824 inhabitants of England and Wales. In 1851 the aggregate number in like manner was 16,426 or 1 in every 1091 of the population. It will be observed that the excess in the number of lunatics in asylums in 1861 over those in 1851 amounts to no less than 7919.

To what is this increase to be ascribed? Are we to conclude that there is an increased liability to mental maladies among the people of this country; or are we to look to other circumstances for an explanation of this remarkable difference? The

explanation is partly to be found in the fact that the increase has been principally in public asylums, and is limited almost entirely to pauper and criminal patients. Since 1851 pauper lunatics, returned in that year at the workhouses, have been freely removed to county lunatic asylums; but making every allowance for this circumstance, it is obvious that other influences have been in operation which have had the effect of increasing the number in asylums.

The Commissioners in Lunacy are of opinion that the increased number of pauper lunatics is chiefly due to the agency of three causes—(1.) The discovery of fit objects for treatment previously unnoticed, and the classification as insane of many persons formerly looked upon as ordinary paupers; (2.) The increased number of these sent to asylums; and (3.) The prolongation of their life when thus brought under care. To what extent the removal of pauper lunatics from workhouses and cottages has tended to prolong life has not been determined; but there can be no doubt that when destitute and diseased persons are placed under care in well-regulated establishments, specially adapted for their protection and treatment, and in which they receive an abundant diet and careful medical attendance, the result will be a diminution of the rate of mortality amongst them. These considerations furnish sufficient reason for rejecting the inference suggested by the increased return of paupers in asylums, that the inhabitants of this country are more prone than formerly to attacks of insanity.

The following table, compiled from the last report of the Lunacy Commissioners, gives the most recent statistics relating to this painful subject:—

	Number of Patients, 1st January, 1863.			Admissions during 1865.	Discharges during 1865.	Number Recovered.	Deaths during 1865.	Patients Remaining 1st January, 1866.			Number deemed Curable.
	Private.	Pauper.	Total.					Private.	Pauper.	Total.	
County and Borough Asylums, . .	208	22,077	22,285	7,468	3,593	2,530	2,517	229	23,414	23,643	2,333
Hospitals, ...	1,815	363	2,178	776	513	289	176	1,885	380	2,265	441
Metropolitan Licensed Houses, . .	1,485	870	2,355	942	595	217	269	1,536	897	2,433	280
Provincial Licensed Houses, . . .	1,669	453	2,122	837	871	205	157	1,627	304	1,931	330
	5,177	23,763	28,940	10,023	5,572	3,241	3,119	5,277	24,995	30,272	3,384
Naval, Military, and State Criminal Asylums, ...	485	—	485	318	172	41	34	597	—	597	95
Totals, ...	5,662	23,763	29,425	10,341	5,744	3,282	3,153	5,874	24,995	30,869	3,479

As regards the ages of the patients in lunatic asylums, a summary of the tables prepared at the time of the last census, gave the following results with regard to England and Wales:—

	Males.	Females.
Under 20 years, ...	364	298
20 and under 40 years, ...	4,700	4,763
40 " 60 "	4,583	5,687
60 " 80 "	1,530	2,252
80 and upwards, ...	72	96
	11,249	13,096

After the fortieth year, mental maladies are more

common amongst women than men, but the excess of females above sixty must be considered as partly due to the superior longevity of that sex.

The former occupations of the insane were given according to the best information which the principal resident officers of the institutions could furnish. It deserves an attentive examination, as it proves that the professional and educated classes furnish a large number of patients: of clergymen and ministers of various religious denominations 95 were returned; of barristers and solicitors, 82; physicians and surgeons, 66; officers of the army and navy, 113 (the military and naval asylums are excluded); schoolmasters and others engaged in tuition—men, 77,

women, 250. Amongst the largest items were—agricultural and other labourers, 2587 (both sexes); female and domestic servants, 2707; shoemakers, 560; milliners, dressmakers, seamstresses, &c., 884; tailors, 296.

The number and distribution of the insane in *Scotland* on 1st January, 1865, exclusive of unreported lunatics placed in private dwellings and maintained from private resources, were as follows:—

Mode of Distribution.	Number.	Private.	Pauper.
In Public and District Asylums, . . .	3125	826	2299
“ Private “ . . .	788	229	559
“ Parochial “ . . .	497	...	497
“ Lunatic Wards of Poorhouses, . . .	428	...	428
“ Private Dwellings, . . .	1630	21	1609
Total, . . .	6468	1076	5392

The following table shows the number of private and pauper lunatics, on the 1st January of each year, since the institution of the General Board of Commissioners in Lunacy for Scotland:—

On 1st January.	Number of Pauper Lunatics.		Number of Private Insane.	
	In Asylums and Lunatic Wards of Poorhouses.	In Private Dwellings.	In Asylums.	As Single Patients under the Sheriff's order.
1858, .	2953	1784	1012	20
1859, .	3103	1877	1011	24
1860, .	3379	1847	971	21
1861, .	3470	1787	992	22
1862, .	3548	1741	1031	21
1863, .	3604	1679	1023	21
1864, .	3683	1637	1018	21
1865, .	3783	1609	1055	21

This table shows, on the whole, great steadiness in the extent and occurrence of lunacy; but it appears from the last report of the Board, that the tendency in most counties, even as regards pauper lunacy, has latterly been rather towards a diminution than an increase. Indeed, in only one county—that of Lanark—has an increase of any magnitude taken place; and the increase there, which in 1863 comprised thirty-nine patients, was more than equal to the total increase for the whole country in that year.

The expenditure for pauper lunatics has increased from 80,652*l.* in 1858 to 102,682*l.* in 1864.

In *Ireland* two inspectors, with the requisite assistants, superintend the various lunatic asylums. There are altogether about twenty district establishments in operation, several of them being for the reception of patients from two or more counties, which have associated themselves for that purpose, and a central one, supported entirely by the Government, and under the immediate control of the inspectors, at Dundrum, county of Dublin. On the 1st January, 1865, there were in public asylums in Ireland, 4672; in poor-

houses, between actual lunatics, epileptics, and imbeciles, 2455; in gaols, ‘criminal’ and ‘dangerous,’ 389; in private licensed houses, 556; and at Dundrum, or the criminal asylum, 127, besides 73 formerly in the Houses of Industry, but now maintained by Government, making an aggregate of 8272. At the corresponding date in January, 1866, the relative proportions were as follows:—In public asylums, 4835; in private asylums, 583; in gaols, 505; in poorhouses, 2733; in Lucan, supported by Government, 64; in central asylum for criminal lunatics, 125, constituting a total of 8845 registered lunatics. This shows a considerable increase (573) in one year. Of the whole, 4403 were males, and 4442 females.

In addition to the above numbers the inspectors believe that there are a great number of persons in some way mentally affected in different parts of the country, who are, comparatively speaking, unprovided for.

In *France* a report was addressed, in 1866, to the Emperor Napoleon by the minister of commerce and public works on the lunatics confined in public and private asylums. It states that at the close of 1860 there were 57 public and 42 private asylums in the 86 departments of France. These were divided among 60 departments, leaving 26 unprovided with any refuge for insane persons. It appears, further, that the number of lunatics in asylums has gradually increased since 1835, when the first official returns were completed, to the 1st of January, 1861, at which period the report concludes. The number confined in asylums was:—

On the 1st of January, 1835, . . .	10,539
“ “ 1842, . . .	15,280
“ “ 1849, . . .	20,231
“ “ 1856, . . .	25,485
“ “ 1861, . . .	30,239

The increase in the number of lunatics within this period of twenty-six years was, on the average, 750 annually.

It appears that the women in the asylums increase in a greater proportion than the men.

Four-fifths of the inmates of the asylums are regarded as incurable. This result is attributable to the lunatics’ relatives, who keep them at home until all cure becomes impossible.

A census was taken throughout France on the 1st of January, 1851, the 1st of January, 1856, and the 1st of January, 1861, of all lunatics, distinguishing those treated at home from those in the asylums. It appeared that in 1851 there were 24,333 lunatics treated at home, and 20,537 in asylums; in 1856, 34,004 at home, and 26,286 in asylums; and in 1861, 53,160 at home, and 31,054 in asylums. These returns show that the lunatics increased within ten years from 44,970 to 84,204. By comparing the number of lunatics according to their sex with the entire population, it will be found that there is one male lunatic for 915 men, and one female lunatic for 839 women. The minister directs the attention of the emperor to the greater mortality among men than among women in lunatic asylums. The average is 130 deaths among men to 100 among women. The following is the number admitted into lunatic asylums between the years 1854 and 1860 inclusive, and the number discharged or deceased:—

	Admitted.	Discharged or Deceased.
1854, . . .	9,234	8,862
1855, . . .	9,302	8,714
1856, . . .	9,246	8,426
1857, . . .	10,024	9,301
1858, . . .	10,314	9,464
1859, . . .	10,686	9,203
1860, . . .	10,785	9,307

During this series of seven years, 68,992 patients were received into lunatic asylums, and 63,277 were discharged or died. Four-fifths of the patients admitted into lunatic asylums are supported by public charity at an expense of a little more than 1s. a head per diem.

In the *United States* the number of insane returned at the last census (1860) was 23,999, and the aggregate number of patients in the different hospitals 11,133, or less than one half; so that the wants of that country in this respect are far from being supplied.

Prevention.—Science has hitherto discovered no medicine which acts as a specific cure for insanity, and none which is a prophylactic or preventive of the disease. The chief power of prevention in the case of each person, lies with that person himself. The man of sound judgment and prudent self-control will be 'moderate in all things,' avoiding those habits, practices, or excesses which exhaust or depress the vital force, allowing himself sufficient sleep to enable the brain and body fully to re-invigorate themselves from the fatigue of ordinary and wholesome labour, and living as near to nature as our multifold artificialities will permit.

The public authorities may do much towards decreasing the proportionate prevalence of the disease. The intemperate use of spirituous drinks is the most fertile exciting cause of insanity. Hence, whatsoever diminishes intemperance reduces, indirectly, the number of the insane. Legislatures may enact wholesome laws aiming at such a diminution; and among those laws let provision be made for the establishment of hospitals or asylums for the treatment of inebriates—a class of institutions which are now one of the greatest of public needs. They would be a blessing not only to the people in general, but also to the hospitals for the insane, to which persons labouring under delirium tremens are now taken, but where they are out of place, almost invariably a detriment to the other patients, and notorious infringers of rules and regulations.

Although the temptation is great to an indefinite prolongation of this article, we shall close with a few words upon some of the popular errors in respect to the insane.

It appears to be generally thought that a belief in the exaltation of self to sovereign power is almost a necessary concomitant of mental alienation. This is far from being the fact, although every hospital for the insane has its kings or its queens, its dukes or its duchesses. The proportion who enjoy this, to them, pleasant delusion, is probably not more than three, certainly not over five, per cent. of the whole number of the insane.

Again, it is almost universally believed that insanity develops or increases deceit, artfulness, craftiness, trickery—that the insane are shrewd, sly, or to

express the whole in one word, the word generally used, 'cunning.' In very rare and exceptional cases this is true, but as relating to the great mass of the insane it is truth's opposite. Remove the patients from any one of our hospitals, and substitute in their places and under the same circumstances, except the one condition of mental disorder, an equal number of persons not insane, and the amount of 'cunning' would suddenly be greatly, and, to the officers and care-takers of the hospital, very annoyingly augmented. With all the modern improvements in the hospitals, the introduction of comforts and the abolition of the means and even the appearances of restraint, still those establishments are, and must ever be, in respect to most of their inmates, places of involuntary detention—of forcible detention, indeed, although the force is exerted with as little demonstration as possible. Now, were the insane one-half as 'cunning' as the sane, there is hardly a hospital in the country that, with its present arrangements and means of confinement, and under its ordinary exercise of oversight and restraint, would not be evacuated by its patients within four-and-twenty hours. In short, we must acknowledge, although it be with sorrow for the latter, that the insane are more truthful, less artful, and less 'cunning' than the sane.

Superadded, however, to the lack of 'cunning,' there is another peculiarity of the insane which renders their detention easy. They form no very intimate alliances. They have not the element of cohesion. They do not confide one in another. Cabals cannot be created. Conspiracies can have no existence. Plots, if involving more than one person, cannot be matured. A disposition of general distrust, and the fact that, as a rule, each insane person perceives the insanity of his fellow patients, though, for the most part, oblivious of his own, sufficiently account for this peculiarity.

But of all the prevalent errors in regard to the insane, there is none other fraught with such deleterious consequences, as the impression that they are most easily governed by deception. It is truly marvellous to one accustomed to their treatment, to perceive how almost universal is the practice, the moment a person loses the healthy use of his mental faculties, for his friends or guardians to resort to falsehood in word and falsehood in action, to lying and all kinds of deception, in the attempt to manage him. How truthful soever men may be towards others, they appear to consider themselves justified in converting themselves into everything that is false toward the insane. This course of conduct usually defeats the very object for the attainment of which it is pursued; for, as a general thing, the insane are suspicious, watchful for deceit, and not obtuse in the power of detecting it; and if it be but once perceived by them, all confidence in the person who has practised it is lost. There will be no further listening to his counsel, no further submission to his wishes, unless he frankly acknowledges his error, promises amendment, and faithfully adheres to that promise. The dislike and even hatred of the nearest relatives and the dearest friends, which is a common and prominent characteristic of the insane, may doubtless, in a great measure, be justly attributed to this grossly faulty method of treatment.

The insane, as is manifest in many things, are much like children. The same policy which will insure a cheerful and wholesome obedience from a child, will meet with a like response from a person suffering under mental disease. As, in the case of parent and child, the mature mind must, as being right in the nature of things, assert and preserve its prerogative over the mind that is immature, so, in the case of a guardian and insane ward, or patient, the sound mind must, because reason is higher than unreason, assume and retain a directing superiority over the mind that is unsound. But this superiority cannot be retained without kindness, candour, truthfulness, and unflinching firmness. Let no false word escape the lips. Let no promise be made hastily; but, being made, let it be most scrupulously fulfilled. Threaten nothing which is not seriously intended. Let 'No' be an absolute negative, and 'Yes' a positive affirmative. Let no course of action be decided upon without mature deliberation; and then, whatever is to be done with or for the patient, let him be freely and candidly told of it, together with the reasons, if demanded, which induce such action. If this be properly done, most patients will quietly submit. With some, however, force will be required; but let it ever be remembered that any necessary amount of force is a thousand times better than deception. We apprehend that there is more than one physician to a hospital for the insane who has had more than one patient say to him, 'I will do as you wish, for you never have deceived me.'

LUNATION, the time between two new moons. [MOON.]

LUND. [SWEDEN.]

LUNDY ISLAND. [DEVONSHIRE.]

LUNE, LUNULE, the figure formed on a sphere or on a plane by two arcs of circles which inclose a space.

LUNE, River. [LANCASHIRE; WESTMORELAND.]

LÜNEBURG, a province of Hanover, situated between 52° 15' and 53° 30' N. lat., 9° 16' and 11° 40' E. long., is bounded N. by the Elbe, which separates it from Holstein, Hamburg, and Lauenburg; N.E. by Mecklenburg-Schwerin and Prussia; E. by Saxony; S.E. and S. by Brunswick and Hildesheim; and W. by Calenberg. The area is 4488 square miles, and the population in 1861 was 367,669. The country is an immense sandy plain, broken by chains of low hills. The surface is chiefly covered with heath, extensive turf moors, and forest woods, mostly fir. Fertile arable land is rare; but on the banks of most of the rivers, especially the Elbe and the Aller, there is very rich marsh land. The principal river is the Elbe, which runs along the frontier, and receives several small feeders in this province. The Aller, in the south of the province, belongs to the valley of the Weser. The country has a very gradual fall towards the Elbe and the Weser, especially towards the former, against the inundation of which the land is secured by dikes. The highest land between the two rivers is the Lüneburg Heath. This tract has some villages and seats of rich land-owners on the small streams that run through it. A breed of small coarse-woolled sheep is kept on this heath. The villagers derive their chief subsistence from tending bees (there are upwards of 200,000 hives

in the district, yielding honey to the value of 40,000*l.* per annum) and gathering bilberries, juniper-berries, and cranberries, of which vast quantities are sent to Hamburg and Bremen. The quantity of corn raised is not sufficient for the population. Flax is extensively cultivated. The land produces also hops, potatoes, garden vegetables, and turnips in abundance, but only a little fruit. The breeding of cattle is more profitable than tillage; the sheep are very numerous, but their wool is in general indifferent. The breed of horses has been lately improved. The manufactures are confined to articles of common household use.

Lüneburg, the capital, is situated in 53° 15' N. lat., 10° 17' E. long., on the Ilmenau, which is here navigable about 15 miles above its junction with the Elbe, and on the Hanover and Harburg Railway. The population in 1861 was 14,411. The town was formerly surrounded with walls, but the fortifications are now dismantled. The principal buildings and public institutions are the royal palace, the gymnasium, St. Michael's church, in the vaults of which are the monuments of the ancient princes, the convent of St. Michael, the town-hall, the arsenal, military academy for nobles, cavalry barracks, hospital, &c. The inhabitants carry on a considerable trade in the products of the country, such as linen, salt, wax, honey, woollens, linen thread, flax, horses, of which 70,000 are annually brought hither to market, &c. There are very productive salt works in a part of the city which is separated from the rest by a wall, and is called the Sülze. Great quantities of lime are burned in the Kalkberg, a hill near the town, and sent to Hamburg and Holland. There are manufactures of soap, breweries, distilleries, a paper-mill, &c., and a very active transit trade is carried on with Hamburg and the interior of Germany. Of the other towns in the province the most important is *Celle* or *Zell*, a tolerably well built town, on the left bank of the Aller, which here becomes navigable, and on the Hanover and Brunswick Railway, 23 miles N.E. of Hanover. It has Lutheran, Calvinist, and Roman Catholic churches, a medical college, and royal agricultural society. Population, in 1861, 14,139. Manufactures of chicory, linen fabrics, hosiery, soap, tobacco, and brandy, are carried on; and there is a good transit trade by the Aller. In the suburbs, which are very extensive, there is a palace with a large garden, in which Matilda, sister of George III., is buried. *Harburg*, on the Elbe, opposite Hamburg, has linen and woollen factories, gunpowder mills, tanneries, wax-bleaching, and stocking-weaving establishments, sugar refineries, and a great trade in timber. Population, 12,243. It is on the Hanover and Brunswick Railway, 4½ miles from Hamburg. Of late years the shipping trade has greatly increased, between 1000 and 1500 vessels now entering and leaving the port annually. There is a custom-house and a citadel, with draw-bridges. *Uelsen in the Heath*, on the Ilmenau, has 3000 inhabitants, who grow flax, and manufacture woollen cloth, camlets, and starch.

LUNEL. [HÉRAULT.]

LUNETTE, in Fortification, is a work similar to a ravelin, or demi-lune, but generally of smaller dimensions. Each lunette is protected in front by a ditch, beyond which is a covered way, as usual.

To give the more advanced lunettes, which are generally those placed beyond the ravelins, all the advantages of which they are susceptible, the magistral lines of their faces should coincide with the sides of an equilateral triangle whose base is a line joining the faces of the two collateral bastions at points about twenty or thirty yards from their flanked angles; for thus the ditches before the faces of the work can be defended by two or more pieces of artillery conveniently placed on the faces of the bastions. The ditches of the retired lunettes should in like manner be defended by artillery placed on the faces of the collateral ravelins. This rule for placing the advanced lunette will permit the ditch and covered-way of the latter to be defended by a fire of musketry from the retired places of arms and from the covered-way before the bastion; and that such fire may graze the bottom of the ditch of the lunette, this ditch ought to be an inclined plane.

Advanced lunettes about a fortress form strong posts for artillery, by which an enemy is compelled to commence his approaches at a greater distance than would otherwise be necessary. The length of their faces may be from sixty to seventy yards, and that of their flanks from fifteen to twenty. The rampart should have the same height above the natural ground as is given to that of the ravelins. But lunettes are only proper for fortresses of the first magnitude, since they would require a large garrison; and the troops, on being compelled to retire, might not find sufficient room in a small place.

LUNÉVILLE, a town in the French department of Meurthe, in 48° 35' 35" N. lat., 6° 29' E. long., and 180 miles E. from Paris, is situated at the confluence of the Vezouse and Meurthe. It has a tribunal of first instance, a college, and 15,528 inhabitants. Léopold, duke of Lorraine, resided here, and built a palace, which was subsequently much improved by Stanislaus, ex-king of Poland. Both these princes made great improvements in the town, which presents wide, straight, and well built streets, and some handsome squares. Behind the palace is the parade ground or Champ de Mars, which covers a space of 500 acres. The other remarkable objects in Lunéville are the parish church; the immense cavalry barracks, with stabling for 6000 horses; the riding school, which is considered the finest in France, being large enough for 200 horse soldiers to exercise in; the hospitals; Jews' synagogue; a theatre, and the Place Neuve, which is ornamented with handsome buildings. Great bodies of cavalry are frequently collected at Lunéville in the autumn for the purpose of manœuvring on a large scale. The town has manufactures of woollen cloth, yarn, hosiery, lace, gloves, earthenware, sheet iron, and beer; it has also a good trade in wine, corn, brandy, hemp, flax, wood, &c. By the treaty of peace signed at Lunéville, February 9, 1801, the Rhine was made the limit between France and Germany.

LUNGS. [RESPIRATION.]

LUNGS, DISEASES OF THE. The highly organized structure of the lungs, and the incessant exercise of their important function, frequently under noxious circumstances, render these organs perhaps the most liable to disease of any in the body. Exposure to damp and cold, sudden atmospherical changes

and transitions of temperature, want of proper nourishment, inattention to personal cleanliness, and some of the mechanical employments in which the confined and heated atmosphere of workshops is impregnated with minute particles of foreign substances, such as steel, wool, &c., may be considered as among the chief exciting causes of this extensively prevailing class of diseases. The diseases of the lungs may be conveniently divided into acute and chronic.

In inflammation of the lungs (*pneumonia peripneumonia*) the air-cells and parenchymatous structure of the organ are the seat of the disease. It is generally ushered in by rigors, and attended subsequently by great fever. There is much difficulty of breathing, and the respirations, which in the natural state are about twenty in a minute, increase in frequency to about forty or sixty. Sometimes there is little cough throughout the disease, but most commonly it increases as the disease advances, and the sputa become more deeply tinged with blood. The features subsequently assume a livid appearance; the breathing gets more oppressed; expectoration is effected with difficulty; the powers of life fail, and the patient dies from the lungs being no longer able to carry on their function.

In the early stage of pneumonia the inflamed part acquires an unnatural density and heaviness from the unusual accumulation of blood in it, but it still crepitates on being grasped. In a more advanced state, the lung is found still more dense, and does not crepitate when squeezed, showing that air is no longer admitted. As in this condition it somewhat resembles liver, it has been termed the stage of hepatization. When the disease has proceeded still further, suppuration may be found to have taken place. The sounds given by the stethoscope are crepitation in the first stage, and an absence of sound in the second. Percussion is dull in both stages.

The treatment of inflammation of the lungs must be conducted on the same general principles as inflammation occurring in any other part. The important nature of the organ renders it necessary to resort promptly to bleeding, sometimes to a very large amount, and on repeated occasions. Antimonials and mercury are highly useful in this affection.

Inflammation is sometimes confined to the bronchial tubes, and is called bronchitis; it may also co-exist with pneumonia. [BRONCHITIS.]

Mortification or gangrene of the lungs, though sometimes occurring as a result of pneumonia, most frequently takes place as an independent affection. Great fetor of the breath, with an expectoration of dark brown, greenish, and fetid sputa, excessive debility, and a cadaverous expression of countenance, are the symptoms by which it is indicated. After death portions of lung are found in a partially decomposed state, of a dark brown or dingy greenish appearance, with a putrid smell.

Hæmoptysis, or Spitting of Blood. Expectoration of blood may occur either by exhalation from the mucous membrane of the air-tubes or from the lesion of a bloodvessel. It generally occurs in early life, from the age of fifteen to thirty-five, and in the former instance may be dependent upon local congestion. This determination of blood to the lungs

may be occasioned by the sudden suppression of some natural or accidental discharge from other parts, as in suppressed or impaired menstruation, or the arrest of a hæmorrhoidal discharge, or by pressure of tuberculous matter. From the latter cause it is frequently a sign of approaching consumption. The expectoration of blood is attended with cough. Sometimes the quantity brought up is very considerable, and is expelled with violence; at other times the sputa are only streaked with it. The expectorated blood is generally of a vermilion colour, and when in small quantities, it is frothy and mixed with air. When the blood comes from the stomach, it is brought up by vomiting and without cough, without the frothy appearance, and is of a dark grumous character.

Pulmonary apoplexy occurs when blood is effused into the parenchymatous structure of the lungs.

Malignant Diseases.—The lungs are also subject to diseases of a specifically malignant nature, such as medullary sarcoma and melanosis; but these rarely occur as a primary affection. The medullary and melanoid matter is deposited in these organs as a secondary affection, in conjunction with its existence in other parts, and frequently in all or the majority of the organs of the body.

The most fatal of all the diseases of the lungs is treated of under **PHTHISIS PULMONATIS**. Inflammation of the Pleura is treated of under **PLEURISY**.

LUPERCI, the priests of the god Pan, and the most ancient order of the Roman priesthood. They were instituted in honour of Romulus and Remus, and so called from *lupus*, a wolf, because that animal was recorded to have suckled them. The place where the priests of Pan assembled was called *Lupercæ*, and his festivals took the name of *Lupercalia*. They continued till the year 496, when, on account of their licentiousness, they were abolished by Pope Gelasius.

LUPINE (*Lupinus*), a very extensive genus of hardy annual, perennial, and half-shrubby plants, commonly cultivated in gardens for the sake of their gaily coloured flowers. The species inhabit Europe, the basin of the Mediterranean, and the temperate parts of both North and South America, especially of the former, where they are extremely abundant; but they are unknown in a wild state throughout all the tropics, except on mountains, and in the principal part of Asia, New Holland, and South Africa.

LUPINITE, a peculiar bitter substance, extracted from the leaves of the *Lupinus albus*; it has a green colour, is translucent, and may be melted.

LUPULINE, a substance extracted from hops, and containing from 8 to 12 per cent. of the vegetable matter to which hops owe their power, and to which the name of *lupulite* has been given.

LUPULITE is nearly colourless, but sometimes of an orange colour: in the former case it is opaque, but in the latter transparent; it has no smell till it is heated, and then it has the odour of hops; its taste is bitter.

LUPUS (the Wolf), one of the old constellations, named in Aratus and Ptolemy simply *Θήριον*, 'the wild beast.' It was not a separate constellation, but was carried in the right hand of the Centaur towards the Altar. The same description is given by Hyginus. In modern maps it is represented as a wolf transfixed

by the spear of the Centaur. It is situated between Centaurus and Ara, directly under Scorpius.

LURCHER, the name of a dog which is a cross between the greyhound and the shepherd dog. It is marked by short ears, thick, wiry, and sandy-coloured hair. The lurcher is quick at scent, a fleet runner, and, when used by poachers, very destructive to game.

LURE. [*SAÔNE, HAUTE.*]

LURGAN. [*ARMAGH.*]

LUS. [*BELOOCHISTAN.*]

LUSATIA. [*LAUSITZ.*]

LUSIGNAN. [*CYPRUS; VIENNE.*]

LUSTRATION (*Lat. lustrum*, 'to purify'), among the ancients a mode of purification by sacrifices and other religious ceremonies. Thus the Romans were accustomed to purify their cities, armies, fields, or people, after any impurity or crime. There was scarce any action performed, at the beginning and end of which some lustral ceremony was not required, to purify themselves, and appease the gods.

LUSTRUM (Greek, *λῦσις*, 'I wash'), was the name applied to a period of five solar years among the Romans; and the termination of this period was generally marked by great religious solemnities. Varro derives the word from *luere*, because the farmers paid their taxes at that time; but others, with more probability, trace the etymology to the purifying sacrifice which was then offered.

It is well known that the most ancient Roman year consisted only of 10 months, or 304 days, and that this year continued to be used for religious purposes. Niebuhr, in his 'History of Rome,' has shown that the *lustrum* was the period after which the beginnings of the civil and religious years were made to coincide; since 5 solar or civil years of 365 days each, containing 1825 days, coincide with 6 religious years of 304 days each, containing 1824 days, with the difference of one day.

LUSUS NATURE. A term applied to a monster or to any thing unnatural in the physical world.

LUTE (*Ital. liuto*, from the Arabic, *el ud*), a musical stringed instrument with frets, one of the numerous varieties of the ancient *Cithara*. Till towards the end of the seventeenth century its practice formed an essential part of a good education, but it has since been partially superseded by the guitar. Mersenne, in his 'Harmonie Universelle' (1636), describes the lute as consisting of three parts: the table, made of fir; the body or belly, of the same wood or cedar, constructed of nine convex ribs joined; and the neck, on which was fixed the finger-board, of hard wood, having nine frets made of catgut. To these is to be added the head or cross, in which the pegs or screws were placed. The lute had at first six strings, or rather eleven, for the five largest were doubled; but the number was gradually increased till it reached twenty-four.

LUTES (*Lat. lutum*, 'clay'), in Chemistry, are substances employed in various operations for closing the joints of apparatus, and especially for connecting retorts and receivers so as to prevent the escape either of the vapour or gases generated during distillation or sublimation. The term lute is also applied to the external coating of clay and sand, or other substances applied to glass retorts, in order that they may support a high temperature without fusing or cracking. Common plastic clay answers sufficiently well in some

cases, but in some small distillations, as of nitric acid, the Fat Lute is used, which is prepared by mixing dried and powdered pipe-clay into a paste with linseed oil; and the joint is further secured, both where this lute is used and in many other cases, by tying it over with moistened bladder. In luting common stills, in which oils or water are merely distilled, linseed meal and water, made into a paste, form an effectual lute.

In luting, or rather coating, glass retorts, in order to enable them to sustain high temperatures, Stourbridge clay or Windsor loam mixed with tow have been used; but they require long drying, and are apt to crack. The simplest mode is that of brushing the retort over with a paste of pipe-clay and water, sifting sand upon it, drying it quickly in the ash-pit of the sand-heat, then covering it again with clay and sand, and repeating the alternate applications and drying till the coating is judged sufficiently thick.

Lutes composed of borax and slaked lime, borax and clay, and of lime, and the white of an egg, are also sometimes used, but caoutchouc is now, perhaps, more generally employed than anything else on account of its flexibility, and consequent non-liability to accident.

LUTHER, MARTIN, or LUDHER, LUTTER, or LÖTHER—for he signed his name in these various ways—was born at Eisleben, in Lower Saxony, on the 10th of November, 1483. When six years old he was sent to the free school at Eisenach, and to gain his daily bread was wont to solicit alms by singing before the houses of the rich and charitable, a custom both then and at a later time with the poor students of Germany. 'Let no one,' says the great Reformer in one of his works, 'speak contemptuously in my presence of the poor fellows who go from door to door, singing and begging bread *propter Deum*! You know the psalm says, *Princes and kings have sung*. I myself was once a poor mendicant, seeking my bread at people's houses, particularly at Eisenach, my own dear Eisenach!'

His father's circumstances improving—the elder Luther was a miner, and in possession now of two furnaces of his own—it was determined that the youthful Martin, already giving evidence of an active and powerful mind, should study the law, and he was entered in 1501 at the University of Erfurt, in Thuringia. For legal pursuits, however, he showed no appetite; his intellect swept away at once the cobwebs and trickeries of the law, and he devoted himself to the study of the *belles lettres* and music. Music throughout life was his favourite art; he taught it to his children, he ranked it next to theology, and was accustomed to say of it: 'Music is the art of the prophets; it is the only other art which, like theology, can calm the agitations of the soul, and put the devil to flight.'

Dividing his attention between the classics and the writings of the schoolmen, young Martin Luther strode forward in his career. At the age of twenty he was honoured with the title of Master of Arts, and then, by the advice of his kinsmen, he began to apply himself to jurisprudence. In the Augustine monastery at Erfurt, which he joined in July, 1505, he excited general admiration in the public exercises by the facility with which he extricated himself from the labyrinths of dialectics. He read assiduously

the prophets and the apostles, then the books of St. Augustine: his 'Explanations of the Psalms,' and his book on the 'Spirit and the Letter.' He studied with earnestness the writings of Occam, whose logic he preferred to that of Duns Scotus and Thomas Aquinas.

An accident, as the world would call it, determined his future career. He saw one of his friends killed by lightning at his side. He resolved thereupon to dedicate himself to God's service, and entered upon a life of the most rigid self-denial. 'If,' he says, 'Augustine went straight to heaven from the walls of a monastery, I ought to do so, as all my brethren would testify. I fasted, I watched, I practised all the austerities of a cenobite, until I absolutely fell very ill.' But as yet, like John Bunyan, he was wandering in the wrong path, and soon he was beset with doubts and fears which wrung his very soul. He lingered long in the valley of the shadow. Often might he be seen at the altar foot, with clasped hands and streaming eyes, declaring himself 'the chief of sinners.' He kept weary vigil throughout the night, wrestling with temptations which sprung from his diseased imagination. 'Jerome and other fathers,' he afterwards wrote, 'never endured such trials. Augustine and Ambrose, too, had their sorrows, and trembled before the sword; but what is this compared with the angel of Satan, "who strikes with the fists?" If I live I will write a book on Temptations, for without a knowledge of the subject no man can thoroughly comprehend the Holy Scriptures, or feel the due love and fear of the Lord.'

A weak mind gives way before these inward struggles; a strong mind, after much buffeting to and fro, rises out of them a conqueror; and Luther was reserved to accomplish a glorious mission—to open up to the intellect of Europe, like Columbus, a New World.

In his twenty-third year the business of his monastery called him into Italy. The journey opened up a new era, not only in Luther's life, but in the history of religion; for the shams and falsehoods and open vices of the Italian capital disgusted his clear moral sense and offended his vigorous intellect. He penetrated into all the mysteries of the papal court, and beneath its flowers and gilding recognized the abomination of iniquity that corrupted the church and society. So, with thoughts arising in his heart that were to prove the germs of a great revolution, he quitted the city of the popes, and shook the dust off his feet.

On his return to his convent solitude he devoted himself to the study of the Scriptures, reading them with the assistance of Erasmus, whose interpretation, however, did not always satisfy him. His renown as a scholar now obtained him the chair of professor of philosophy in the university which Frederick the Elector of Saxony had founded at Wittemberg (1508). Here he addressed himself to a full and lucid exposition of the divine word, and enunciated opinions which, though as old as the days of the apostles, fell upon his startled hearers with all the effect of novel truths. So long, however, as his doctrines were promulgated from the professorial chair, they exercised but little influence, because they were confined to a limited audience; but through the influence of Staupitz he passed from the chair to the pulpit, and

flung out his genius upon the multitude. Crowds flocked to hear this bold and original teacher, who spake as man had never spoken since the age of the primitive Fathers, and who put new life into the dry bones of an antiquated theology. He had not yet, however, stepped forward as the reformer. His foot was on the threshold, but custom and traditional influences still held him back. His mind required an external impulse to assist it in throwing off its fetters, and this impulse was afforded unwittingly by a Dominican monk named Tetzel. The resources of the Roman see proving inadequate to the accomplishment of the many ambitious projects which filled the teeming brain of Pope Leo X., he resolved to increase them by the sale of indulgences, and to draw fresh funds from the credulity and superstition of mankind. He commissioned Tetzel to hawk these indulgences, or licenses to sin, about Germany. The monk was fully equal to the task. There was no crime, however atrocious, which he would not remit for money. He was not content with pardoning known sins, but laboured to invent the foulest and most prurient enormities, and when he saw his hearers terrified by each loathsome idea, he would coolly add: 'Eh, well, all these are absolved as soon as your gold chinks in the pope's treasury!'

Luther was struck with amazement and horror at such open blasphemy. 'When I beheld,' he says, 'this unholy and detestable traffic taking place in open day, and thereby sanctioning the most villainous crimes, I could not, though I was then but a young doctor of divinity, refrain from protesting against it in the strongest manner.' He thundered resolutely against the monk and his mission; Tetzel retorted; Luther, growing bolder in the cause of truth, stepped into the arena, armed at all points. On the 31st of October, 1517, the eve of All Saints, he nailed to the church door ninety-five theses against the doctrine of indulgences, and announced his readiness to defend them. A copy found its way into the hands of Tetzel, and excited his alarm and indignation. He published a hundred and six counter-propositions, in which he asserted the pope's infallibility, and branded Luther and all who abetted him as heretics and heresiarchs. The discussion spread. The introduction of printing and the consequent diffusion of books had already awakened a spirit of inquiry, and the people threw themselves with eagerness on the religious pasture from which they had been so long excluded. Luther's theses were printed in thousands, devoured, and circulated in every direction, so that even their author was alarmed at his success. He was not yet prepared to throw off the authority of the pope, and at this juncture seemed disposed to abandon the whole matter. But his pacific resolve was shaken by Tetzel, who had burned the heretical theses in public, and, as it were, dared Luther to the conflict. The inhabitants of Wittenberg retaliated by consigning Tetzel's productions to the flames in the Great Square, and thus began the great religious revolution known as the Reformation. Numerous sleuth hounds joined in the chase which Tetzel had started; John Eck, Prierio, and Hoogenstraeten opened upon him in full cry. At first the commotion was viewed with indifference at Rome. 'Monkish jealousy,' cried Leo X.; 'this friar Martin is a man of fine genius!' And when Luther appealed

to him against the lawfulness of indulgences, he privately requested his friend Staupitz to persuade the reformer to rest in peace. But when at length the pope's master of the ceremonies wrote a defence of Tetzel, and Luther published a reply, in which he completely annihilated its pseudo-logic, the alarm and ire of the papal court were fully aroused. He was summoned to appear at Rome within sixty days, and Prierio, one of his most furious antagonists, was placed at the head of the tribunal appointed to try him. But the elector of Saxony, who was favourable to Luther, knew well that if he ventured to Rome he ventured into a lion's den from which there was no hope of return, and demanded of the pope that the German monk should be tried in his own country. His influence procured the concession that he should be examined by a legate in the free town of Augsburg, where the elector himself was then residing. With the courage born of faith Luther proceeded thither, journeying afoot, without a krentzer in his pocket, and in a worn-out gown. At the gates of Augsburg he was received by a crowd of priests and laymen, rich and poor, who welcomed him in God's name. Before the legate, Cardinal Cajetan, he preserved his wonted composure, and defended his convictions with earnest eloquence. The cardinal called upon him to retract, or threatened him with the vengeance of the church. A four days' dispute ensued, in which the reformer's arguments proved irresistible, and Cajetan broke up the examination in great disorder. The monk returned in safety to his cell and his pulpit. 'I leave the place,' he wrote to the cardinal, 'in the name of the Lord, and I appeal from Leo misinformed to Leo better informed.' Between Luther and the papal court reconciliation was henceforth impossible, and it was well for him that he had secured the protection of a patron so powerful and so sincere as Frederick of Saxony.

Day by day the breach widened. Luther still retained that feeling of deference towards the church which springs from tradition and prescriptive authority, and to sunder the thrall that bound him an external impulse was again necessary. It was at this time that John Eck put forth a public challenge to Luther to dispute with him at Leipzig. Thither proceeded the reformer, accompanied by Carlstadt, Melancthon, and a large body of students. A fierce debate ensued, in which logic was on Luther's side, and authority on that of Eck. But unhappily for the pope the course of the discussion led the Wittenberg professor to examine the papal claims to the primacy, and he soon found reason to assume a bolder tone and adopt a more vigorous course. Through the printing press he appealed to the people, and his voice stirred the heart of Germany like a trumpet. In October, 1520, he issued his indictment against the papacy in a work of great power and furious invective, entitled 'The Babylonian Captivity of the Church.' He set forth that the church was held in bonds, and that the Saviour, constantly profaned in the idolatry of the mass, and scornfully disregarded in the dogma of transubstantiation, was virtually the pope's prisoner. A bull of excommunication arriving from Rome stimulated him to further onslaughts. He immediately issued a pamphlet 'Against the Execrable Bull of Anti-Christ,' and on the 10th of December publicly burnt the papal anathema at

the gates of Wittenberg, with the canon law, the decretals, and the extravagances of the popes, exclaiming—'As thou hast afflicted the holy of the Lord, so mayest thou be consumed in everlasting fire.' In an address he added—'Hitherto I have merely jested with the pope; the serious struggle now begins.' And from that date Luther held no more communion with the Church of Rome.

The circumstances of the time, as we have said elsewhere, proved eminently favourable to the success of Luther's mission. The discovery of printing had aroused the intellectual faculties of men, while it provided the means of supplying them with the nutriment they so long had lacked. The printers, necessarily men of bold and quick intelligence, became Luther's most powerful and enthusiastic supporters. They frequently printed his books at their own cost, and always with a loving care. Vast numbers of copies were struck off, and rapidly distributed throughout Germany by those heretical monks who had thrown aside their cowls and returned to the world to promulgate the principles of a reformed creed. The fire was latent in the earth, and as the vivifying flame passed quickly from one point to another, it burst forth in all its brilliancy, lighting up the civilized world with the reflection of its radiance. The nobles and the peasantry, the castles and the free towns, feudalism and commerce, rivalled each other in enthusiasm for Luther. At Marienburg, at Strasburg, even at Mentz, there prevailed a constant struggle for his smallest pamphlets. The sheet, while yet wet from the press, passed from eager hand to hand. The literary guilds then flourishing in Germany, tinmen and shoemakers, braziers and tailors, greedily devoured the good tidings proclaimed by the reformer. Hans Sach, the shoemaker poet, celebrated in his most melodious strains the 'Nightingale of Wittenberg,' and the song, as it spread over all the German land, swelled into the trumpet-tones of a victorious pæan. The German nobles were foremost in this new communion of thought and sentiment. They supported the hero-reformer with money; they promised him active aid against all assailants. 'I see very clearly,' wrote Ulrich von Hutten, 'that we must come to swords, bows, armour, and cannon. Do thou, my father, fortify thy courage, and despise these wild beasts. I see each day the number of thy adherents augment; thou wilt be in no want of defenders.' The friends of Luther were even present in the Diet at Worms, and in one of the sittings a paper was produced which set forth that four hundred nobles had sworn to defend him, and he who read it cried aloud—'Buntschuh! Buntschuh!' the war cry of the insurgent peasantry.

Charles V., king of Spain, had been recently crowned as emperor of Germany at Aix-la-Chapelle, and his first Germanic Diet was summoned to assemble at Worms in 1521, with the avowed object of checking the progress of the new and dangerous opinions. The papal party, headed by Alexander, prevailed upon the young emperor to issue an edict for the destruction of Luther's writings. The States, however, refused to publish the decree unless the reformer were heard in his own defence, and a safe-conduct granted him under which he might repair to Worms. His friends would have had him dis-

regard the imperial mandate, but Luther was wiser and bolder, and seized the opportunity of proclaiming the truth before the great German council. His journey to Worms resembled a triumphal procession. When he came in sight of the city, on the 16th of April, he rose in his chariot and chanted the noble psalm—the 'Marseillaise of the Reformation'—*Ein feste Burg ist unser Gott* ('A safe stronghold our God is still'). Before the Imperial Diet he maintained the same sublime confidence in the help of heaven, and expounded his doctrines with all the eloquence of a vigorous and truth-fearing soul. Neither promises nor threats could induce him to retract. 'The word of God,' he said, 'is not my word, and I cannot abandon it. Here am I,' he exclaimed; 'I cannot do otherwise; so help me God. Amen!'

On the 26th of April he left Worms. An imperial edict was straightway issued against him, and all persons were prohibited from affording him any assistance or asylum, under penalty of high treason. As the only mode of saving his life, the friendly elector caused him to be arrested when on his way to Alterhausen, and provided for him a secure abode in his castle of Wartburg, where he was safe from the persecution of his sanguinary foes. He spent a year in this solitude, lamented by those of his friends who were not in the secret of his concealment, and occupied his time in a portion of his great work—the translation of the New Testament into German. The version was published in 1522. But his secluded and sedentary life filled him with morbidly nervous sensations. He imagined himself to be troubled with the frequent presence of the Evil One, in the form of a buzzing moth; and they still show the pilgrim to Wartburg the black mark on the wall which records the flight of an inkstand hurled at the intruder by the reformer's vigorous hand. He soon, however, shook off these wild delusions, and learning that Carlstadt and the more violent reformers were proceeding with such intemperance as to damage the cause of truth, he left the castle in March, 1522, and returned to Wittenberg. His influence and his energy speedily stilled the commotion that had arisen.

In the middle of the same year, Henry VIII. entered the lists of polemical controversy, and published a reply to Luther's 'Babylonish Captivity.' The reformer answered it with his wonted vehemence, and completely crushed the royal logician. In 1525 he still further asserted his independence of the Romish church by marrying a nun, Catherine von Bora, who had escaped from her convent about two years before. She was descended from a noble family, was twenty-two years old, and of a handsome person. Though tried by the miseries of extreme indigence, the union proved a happy one, and Luther found in his wife a helpmate and a consoler. Four children were born to him, and in his domestic relations the reformer showed himself endowed with a heart as true and tender as his intellect was bold and aggressive.

From this time forward the life of Martin Luther flowed on with the fullness and steadiness of a great river. His labours were incessant, for work was the necessary condition of his active spirit. The publication of his German version of the Scriptures was not only an epoch in the history of religion, but in the formation and development of the German tongue.

By the year 1533 seventeen editions of it were published at Wittenberg, thirteen at Augsburg, thirteen at Strasburg, with reprints at Erfurt and Leipzig. The bread was freely cast upon the waters, and was eagerly sought by exultant thousands. Many of the German States embraced the Lutheran creed, and its apostle found himself called upon to organize and superintend the new churches that sprang up around him. From 1517 to 1526 a book or tractate from his pen marked every year, and he wrote able and learned commentaries on nearly all the books of the Bible. In 1525 a council was held at Augsburg, which adjourned to Spire in 1526, and at it a general council was demanded. In 1529 a Diet was assembled at Spire, which determined on suppressing by force the further promulgation of the new doctrines. Against this intolerance several of the German princes, and the deputies of fourteen imperial towns, solemnly protested, and hence arose the glorious appellation of Protestants—Protestants against falsehood, bigotry, and the perversion of God's truth—which has ever since been borne by the members of the Reformed church.

At this period occurred the famous Sacramentarian controversy in reference to the supposed presence of the body and blood of Christ in the Eucharist. On this point Luther had not shaken himself free of Romish trammels. He still clung to the dogma of the Saviour's actual presence, and to all arguments replied, 'This is my body.' The discussion had no profitable result, but excited much ill feeling between Luther and the Swiss reformers, who stoutly opposed the doctrine of transubstantiation.

In 1530 was held the memorable Diet of Augsburg, at which the Confession of Faith prepared by Melancthon was formally accepted, and Protestantism, from the dream of a solitary monk, rose to the dignity and substance of a national creed. It was immediately followed by an assemblage of the Lutheran princes at Smalcald (December 31, 1530), where they entered into a mutual league of defence, and agreed, if necessary, to maintain their religious opinions by arms. The Smalcaldic League was the first movement of the Thirty Years' War, which, in the course of its desolating career, brought all Europe within its influence, until the Treaty of Westphalia secured the rights and liberties of the European States.

To the excesses of the Anabaptists it is unnecessary to allude, except in record of the sorrowful indignation with which they filled the soul of Luther. The reformer continued at his labours, earnest and resolute, till, in his sixty-second year, his health began to succumb. On the 23rd of January, 1546, he repaired to Eisleben to effect, if he could, a reconciliation between the Counts of Mansfeldt. In this labour of love he succeeded; a fitting conclusion to his great and glorious career. On the 17th of February he complained of severe ailments in the chest, and became so ill that a conviction of speedy death forced itself upon his mind. He passed an uneasy night, and on the following day gradually sank. 'Friends, I am dying,' he said to the anxious faces that thronged his chamber, 'I shall remain with you at Eisleben.' He repeated fervently the prayer, 'Into Thy hands I commit my soul; Thou hast redeemed me, O God of truth!' 'Reverend Father,' said his physician, 'do you die steadfast in the faith

that you have taught?' Not a doubt flung its shadow upon his soul in that supreme moment, and in a tone of indescribable earnestness, he answered, 'Yes.' He then fell asleep, and in a few minutes, breathing one deep sigh, surrendered his spirit to God. He is supposed to have died of angina pectoris, or, according to other authorities, of cancer in the stomach. His remains were conveyed in a leaden coffin to Wittenberg, and interred on the 22nd of February with the highest honours.

'Luther's face,' says Carlyle, 'is to me expressive of him; in Kranach's best portraits I find the true Luther. A rude plebeian face, with its huge crag-like brows and bones, the emblem of rugged energy; at first, almost a repulsive face. Yet in the eyes especially there is a wild, silent sorrow; an unnameable melancholy, the element of all fine and gentle affections; giving to the rest the true stamp of nobleness. Laughter was in this Luther; but tears also were there. Tears also were appointed him; tears and hard toil. The basis of his life was sadness, earnestness. In his latter days, after all triumphs and victories, he expresses himself heartily weary of living; he considers that God alone can and will regulate the course things are taking, and that perhaps the day of judgment is not far. As for him, he longs for one thing; that God would release him from his labour, and let him depart and be at rest. They understand little of the man who cite this in discredit of him! I will call this Luther a true, great man: great in intellect, in courage, affection, and integrity; one of the most lovable and precious men. Great, not as a hewn obelisk, but as an alpine mountain—so simple, honest, spontaneous, not setting up to be great at all; there for quite another purpose than being great! Oh, yes! unsubduable granite, piercing far and wide into the heavens; yet in the clefts of it fountains, green beautiful valleys, with flowers! A right spiritual hero and prophet; once more, a true son of nature and fact, for whom these centuries, and many that are to come yet, will be thankful to heaven!'

Luther's character had in it much of the heroic. He was not to be cowed by dangers, not to be daunted by obstacles; these to his ardent spirit were but incentives which stimulated him to greater efforts. He was fond of the clash and clang of battle. It was in moments of extreme peril that he felt all the depth and power of his great soul, and knew of what grand deeds he was capable. At the first sound of conflict his spirit rushed to arms, 'eager for the fray.' The blows he dealt were heavy, crushing, irresistible, for he was held back by no false sentiment; and when a sham was to be exposed, or a falsehood destroyed, his arm had a giant's might. Yet his was a heart of infinite tenderness, and in his family affections and his friendships he showed himself generous, forbearing, loyal. It is true the gold was not without alloy. There was a certain ruggedness about his nature which could not but offend the dilettante lovers of 'rosé-water revolutions;' but take him for all in all, and it may well be doubted whether the last nineteen centuries have seen a nobler man. Certainly never was man better fitted for the work he had to do, and which he did so successfully; work not unworthy of an apostle, and whose glorious results we at this day gratefully acknowledge.

(For authorities, consult Michelet, *Life of Luther*; Audin, *Histoire de Luther*; Blackwood's Magazine, December, 1835; Adams, *Scenes from European History*; D'Aubigné, *History of the Reformation in Germany*; Mosheim, *History of the Lutheran Churches*; Ranke, *History of the Reformation*; Coxe, *House of Austria*, &c.)

LUTHERANS, a name given to a sect of Protestants who profess to follow with the utmost strictness the doctrines expounded by the great German reformer. The German Protestants are all Lutherans. They have one or two places of worship in London.

LUTI, BENEDETTO, was born at Florence in 1666. He was the scholar of Gabbiani, and went about 1696 to Rome, where he died in 1724. Luti has been called by some the last of the Florentine masters. He painted in fresco, in oil, and in pastel. His masterpiece is the large picture of the Vision of San Ranieri, in the cathedral of Pisa.

LUTON. [BEDFORDSHIRE.]

LUTRA. [OTTER.]

LUTTERWORTH. [LEICESTERSHIRE.]

LÜTZELBURGHER, or LEUTZELBURGER, HANS, called also Hans Frank, a famous Swiss wood-engraver of Basle. He lived in the early part of the sixteenth century. There are many other celebrated old cuts, some from drawings by Holbein, attributed to Lützelburger.

LUTZEN, in Germany, a town in Prussian Saxony, in the government of Merseburg, nine miles S.E. of Merseburg, and on the Elster river canal. Population about 2500. It contains a church and a small castle, but no public buildings of importance, or any manufactures. Its interest is purely historical, and derived from the great battles of which the neighbouring plain has been the scene. A recent writer describes this plain as a rich and joyous looking expanse, studded with villages and tall ungainly church steeples; here and there, bedded in the soil, one of those problematical boulders of dark red granite which the glaciers transported hither, according to modern belief, from distant Scandinavia, and which now chiefly serve as landmarks; far in the south, the first blue outlines of the Erzgebirge faintly show themselves. This vast level has been the battlefield of Northern Germany from the earliest historic times. Here, or in the immediate neighbourhood, Henry the Fowler defeated the Huns in 934. Here were fought the two battles of Leipzig or Breitenfeld, in the Thirty Years' War. Here Gustavus Adolphus fought and died, on the 6th of November, 1632, for the great cause of civil and religious liberty. And here Napoleon was repulsed by the allied armies in 1813. Not an ear of corn is pure from the blood of men.

'Lutzen,' says Mr. Herman Merivale, 'is a thoroughly old-fashioned, forgotten looking town, with walls and fosse partially preserved, and the open country on all sides extending close up to them. It has now about 500 houses, and is traditionally reported to have been more considerable in olden times.' About three-quarters of a mile beyond the town, on the Leipzig road, stands a rough mass of porphyritic stone—the Schwedenstein, or Swede's stone. It commemorates the death of the great Protestant hero, Gustavus Adolphus, who fell close

to the spot where it stands. It bears the inscription 'G. A., 1632,' is surrounded with a little shrubbery and gravel walk, and surmounted by a Gothic arch of cast iron.

The battle in which the Swede king fell may be said to have secured the liberties of Protestant Germany, while it crushed the pretensions of Austria to the supremacy of Europe. The Swedish, or rather allied army, for it included English, Scotch, and Germans in its ranks, consisted of about 25,000 men; the Imperialists, under Wallenstein, duke of Friedland, numbered 20,000, while at Halle, sixteen miles to the north-west, lay Pappenheim with 16,000 men, the greater portion of whom he brought upon the field in the course of the struggle. The attack was delivered by the Swedes about eleven o'clock, and the fight continued with varying fortune until night closed over the conquerors and the conquered. Both sides fought desperately, but the superior discipline and religious enthusiasm of the Swedes prevailed, and the Austrian army was almost annihilated.

Gustavus was slain early in the battle. Wounded in the shoulder by an Austrian trooper, he fell from his horse with a groan, and his page, Lobeling, being unable to lift him again on his charger, he lay exposed to the enemy's cuirassiers. Some of these riding up fired a pistol through the hero's head, and terminated his bright and glorious career in the thirty-ninth year of his age. His memory is still so cherished in Germany, that his portrait adorns almost every cottage wall.

The second great battle of Lutzen was fought in 1813, between the French army, commanded by Napoleon in person, and the allies, under the Emperor Alexander, Blücher, Moreau, and Schwartzberg. Napoleon, after a desperate struggle, was compelled to retreat.

LUXEMBURG, formerly a grand duchy in the kingdom of the Netherlands, but now divided between Holland and Belgium, is bounded E. by Prussia, N. by Liège, W. by Namur, and S. by France. *Dutch Luxembourg*, the possession of which gives the king of Holland the title of Grand Duke, and a voice in the German Confederation, lies east of Belgian Luxembourg, and has an area of 979 square miles, with a population in 1863 of 202,313. *Belgian Luxembourg* is the largest and more western part of the former grand duchy; it has an area of 1690 square miles, with a population in 1861 of 203,597. The principal rivers of Luxembourg are the Moselle, the Sûre, and the Our, which form the boundary between Dutch Luxembourg and Prussia; the Elze or Alzette, a feeder of the Sûre; the Semois, which rises near Arlon, and flows west into the Maas; the Ourthe, which rises near Bastogne, and falls into the Maas near Liège; the Lesse, which rises near Neufchâteau, and falls into the Maas near Dinant.

Luxembourg is crossed from south-west to north-east by a range of high ground, part of the Ardennes, which separates the valley of the Maas from that of the Moselle. The soil of this elevated region is calcareous, and is principally occupied as pasture. The lower lands are very productive, and yield abundant harvests of wheat, rye, flax, hemp, mangelwurzel, &c. Such of the high lands as are tilled rarely yield anything but rye, oats, and potatoes. Large forests are found in many districts. Agric.—

ture is in rather a backward state. The vine is cultivated on the banks of the Moselle and the Sûre. The quality of the wine is inferior. In Dutch Luxemburg there is a great number of distilleries, and some iron works. Horses, horned cattle, swine, and sheep are numerous. The former are much prized for agricultural and military purposes. The latter are exported in large numbers. In the Belgian province there are iron works, slate quarries, potteries, tanneries, cloth, and paper mills. Iron and lead mines are worked; copper is also found.

The city of *Luxemburg*, the capital of Dutch Luxemburg, is a fortress of great strength, in 49° 37' N. lat., 6° 9' E. long., on the Elze, 76 miles S.S.E. from Liège, and has about 12,000 inhabitants. The city is surrounded by strong walls and deep ditches, and has a double line of outworks in the form of a heptagon. It stands partly on a rocky height, and partly in the plain below, communicating by flights of steps and zig-zag streets, impassable by carriages. Its works have been greatly strengthened of late years, and its Federal fortress is garrisoned by 6000 Prussian troops. It has an atheneum, public library, and a small museum; cannon foundry, and iron forges; and manufactures of linens, leather, and tobacco. It was taken by the French in 1795, and made the capital of the department des Forêts. *Echternach*, a walled town on the right bank of the Sûre, 17 miles N.E., has a population of 3726, who are occupied with the manufacture of damasks and paper.

In the Belgian province the chief town is *ARLON*. The only other towns worth notice are *Bastogne*, population 2265; and *Bouillon*, the capital of the ancient Duchy of Bouillon, which stands near the French frontier, on the left bank of the Semoy, and has 2703 inhabitants.

Dutch Luxemburg, united with Limburg, occupies the eleventh place in the Germanic Confederation, and furnishes a contingent of 2706 men to the Federal army.

LUXOR. [THEBES.]

LUXUEIL. [SAÔNE, HAUTE.]

LUZERN (*Lucerne*), a canton of Switzerland, bounded N. by Aargau, E. by Schwytz and Zug, S. by Unterwalden, and W. by Bern. Its greatest length from N. to S. is 33 miles, and its greatest breadth 27. Its area is 480 square miles; and the population in 1860 was 130,504, nearly all Roman Catholics. The constitution is democratic. The Great Council is composed of 100 deputies, presided over by a *schult-heiss*, or judge. The declivity of the valleys is towards the N.E. and N.W. The southern part of the canton belongs to the basin of the Reuss, which issues out of the Lake of Luzern or Waldstätter, at the town of Luzern, and flows N.E. into Aargau. Below Luzern the Reuss is joined by the Wald-Emme, which rises at the S.W. extremity of the canton. A succession of high grounds, running across the middle of the canton, divides the basin of the Reuss from that of the Aar, to which latter river the northern part of Luzern belongs. North-east of the Sempach Lake, which is in the centre of the canton, is another lake, called the Baldeg Lake. The only mountains in the canton are at its southern extremity, on the borders of the Unterwalden and the Bernese Oberland. None of them attain the limits of perpetual snow. The

highest is Mont Pilatus, south-west of the town of Luzern, and a conspicuous feature in its landscape. It is a mountain group nearly 30 miles in length, extending along the borders of Luzern and Unterwalden, and having seven peaks, of which the Tomlishorn (6858 feet) and the Esel (6678 feet) are the highest. The view from these summits is very extensive. The soil of Luzern is fertile; it is one of the very few cantons of Switzerland which produces more corn than it consumes. Fruit trees are also abundant; the vine is cultivated in some favourable situations. The rearing of cattle is the principal branch of industry in a great part of the canton. In some districts there are manufactories of linen and cotton goods. The trade between Switzerland and Italy by the St. Gothard employs a number of people, and all the goods pass through Luzern and the Waldstätter Lake. A steamer runs from end to end of Lake Luzern twice a day in the summer.

German is the language spoken. Luzern is in the diocese of the bishop of Basle, who resides at Soleure; and it is the chief of the Roman Catholic cantons.

LUZERN, the capital of the canton, is situated at the western extremity of the Waldstätter Lake, and is divided into two unequal parts by the Reuss, which issues out of the lake. The larger part, which is on the right bank, is built on the slope of a hill; the whole is surrounded by old walls flanked by watch towers. The interior of the town presents streets narrow, uneven, and ill paved. The remarkable buildings are—the cathedral, several other churches, convents, the town-house, the college of the Jesuits, the arsenal, with ancient armour, and the three covered wooden bridges, which are the chief curiosities of Luzern, being adorned with ancient paintings. The parochial church and cemetery are outside of the town, and are well worth visiting. Luzern contains 11,522 inhabitants. It has two hospitals, a savings' bank, a friendly society, and other benevolent institutions. It has also a collection of minerals, and very good elementary and secondary schools. Luzern is one of the three seats of the Swiss Diet. It has manufactures of silk and cotton fabrics, and carriages, and a large weekly corn market. The forces of the Sonderbund were defeated near Luzern by the Federal army of the Swiss Diet, under General Dufour, on the 24th November, 1847. [SWITZERLAND.]

LUZERN, or LUCERNE, LAKE OF, also called the 'Lake of the Four Forest Cantons' (*Vierwaldstättersee*), from its being surrounded by the cantons of Luzern, Schwytz, Uri, and Unterwalden, is the largest and finest basin of water in central Switzerland. Elevation above the sea-level, 1406 feet; length from N. to S. about 25 miles; breadth from N.E. to S.W. about 9 miles; depth, near Luzern, 300 feet, and towards the E. and S.E., 600 to 900 feet. The scenery which borders upon it presents every variety of landscape, from spots as wild and savage as the Scottish Highlands, to others as rich and beautiful as the fairest parts of Italy. It is navigated by several steamboats. Chief towns, Luzern, Alpnach, Küssnacht, and Flüchen.

LUZON. [PHILIPPINES.]

LU'ZULA, a genus of plants belonging to the natural order *Juncaceæ*. *L. sylvatica*, the great Woodrush, is found in shady places in Great Britain.

L. campestris is common in the pastures of this country, and seven species are natives of the British Islands.

LYCANTHROPY (*lykos*, 'a wolf,' and *anthropos*, 'a man'), a medical term for a species of insanity produced by the bite of a rabid dog, which causes the sufferer to make a noise resembling the howling of a wolf.

LYCAONIA, a district of Asia Minor, is first mentioned by Xenophon, who describes it as extending eastward from Iconium in Phrygia to the borders of Cappadocia, a distance of about 110 English miles. ('Anab.,' i. 2, s. 19.) But in the time of Strabo the name of Lycaonia was applied to the south-eastern part of Phrygia.

Lycaonia is described by Strabo as high table-land, deficient in water. Iconium, the principal town of Lycaonia, and at present Konieh (Strabo, xii. 6; Cic., 'Fam.,' xv. 4; Plin., 'Nat. Hist.,' v. 25), was situated in a fertile plain at the foot of Mount Taurus. Isauria is mentioned by Strabo as part of Lycaonia; it contained the cities of Larauda, Lystra, and Derbe; the two last of which were visited by St. Paul. (Acts xiv. 6.)

LYCEUM, in Greek antiquity, a famous academia or school situated upon the bank of the Ilissus at Athens. It consisted of several porticoes, and numerous open and covered walks, where Aristotle instructed his scholars in the principles of philosophy and logic. As he and his admiring retinue walked there daily until the hour of anointing, they received the name of *Peripatetics*. In modern usage the term signifies generally an educational establishment, and is sometimes applied to literary institutions. The French word is *Lycée*.

LYCHNIS, a genus of plants belonging to the natural order *Caryophylleæ*, and to the sub-order *Sileneæ*. *L. Chalcidonica*, the Scarlet Lychnis, produces scarlet, rose-coloured, or white flowers, and is a great favourite in our gardens; it is a native of Siberia and Japan. Several varieties of this plant have been named. *L. grandiflora* has large beautiful scarlet flowers, and is a native of China and Japan. *L. flos cuculi*, Ragged Robin, has rose-coloured petals, and is an abundant plant in the moist meadows and pastures of Great Britain, as well as the whole of Europe. *L. vespertina*, White Campion, is a common plant in the hedge-banks of Europe. This and *L. diurna*, Red Campion, are frequently regarded as varieties, and then named *L. dioica*.

LYCIA, a province of Asia Minor, was bounded on the N. by Phrygia, on the E. by Pamphylia, on the W. by Caria, and on the S. by the Mediterranean Sea. The interior of this country was entirely unknown till the recent discoveries of Sir C. Fellows, which have corrected the erroneous representations of the maps. The coast is bordered by lofty mountains, but there are no high mountains in the interior. The Xanthus, which has been represented as a small stream, is a river of considerable length, flowing from the mountains in the north of Lycia; and the whole of the interior is a fertile plain, surrounded by mountains, and drained by the Xanthus.

That Lycia was early colonized by the Greek nation is evident, not only from the account of Herodotus,

but also from many other Lycian traditions, as well as from the worship of Apollo, which was spread over the country. Xanthus was a Cretan settlement. The chief temple of Apollo was at Pátara.

In the time of Strabo the Lycians had a kind of federation consisting of twenty-three cities, which sent deputies to an assembly, in which a governor was chosen for the whole of Lycia, as well as judges and inferior magistrates. All matters relating to the government of the country were discussed in this assembly. The six principal cities, Xanthus, Pátara, Píñara, Olympus, Myra, and Tlos, had three votes each; other cities two votes each; and the remainder only one each. In consequence of dissensions between the different cities, this constitution was abolished by the Emperor Claudius; and the country was united to the province of Pamphylia.

The country is now well inhabited, chiefly by Turks, many of whom lead a life half settled and half nomadic; they are distinguished by their excellent character. Most of them are farmers or herdsmen; trade is chiefly carried on by Armenians and Greeks, who live in the sea towns, and form the greater portion of the population of the inland town of Almali, which is the largest in Lycia, the population being about 25,000. The Turkish population is exceedingly careless about money, and when they have enough to eat and to drink—and they are moderate in their habits—they are satisfied, and care for nothing more. The breeding of horses is carried on to a great extent, and herds of many hundreds are often seen grazing together in the valleys. The only kind is that of which such spirited representations are seen in the ancient marbles; the head is of Arabic cast, the chest is very large, the feet are remarkably fine and thin, and the ears are small, as in the antique. They are not shod. No part of Asia Minor contains such splendid valleys as those of the Xanthus and the Dolomon Chái. Myrtle, oleander, and pomegranates cover the banks of the rivers; the plains along the rivers are well cultivated, and in many places the fields are inclosed by fences of myrtle and the small prickly oak, mixed with the orange, the wild olive, the pomegranate, the elegant green storax, which are most beautifully matted together by vine, clematis, and many other climbers. The hills are covered with large oaks and planes, which supply excellent timber. The high plain round Almali, which is 4000 feet above the sea, is one of the largest and best cultivated corn tracts in Asia Minor; its chief produce is barley, which is the common food for horses. Maize is chiefly raised in the valleys and on the coast.

(Fellows, *An Account of Discoveries in Lycia; a Journal written during an Excursion in Asia Minor*.)

LYCIUM. Many ancient authors, and among others Dioscorides, describe under the above name a substance as used in medicine, which is stated to be of two kinds; one obtained from Lycia and Cappadocia, and the other from India. The former is said to be the produce of a thorny shrub called *Pyzanthus*. The latter is stated to be more valuable and efficacious as a medicine, and to be produced also by a thorny shrub, which is called *Lonchitis*. This, however, appears not to be the case, and Dr. Royle has stated his reasons for believing that this sub-

stance is the produce of various species of the genus *Berberis*.

LYCODON, a genus of innocuous snakes, of which we may give the *Lycodon Capensis*, Smith (*Lycodon Horstokii*, Schlegel), as an example.

LYCOPERDON (Gr. *lukos*, and *perdomai*), a genus of fungi, emitting when burst, either by violence or natural dehiscence, a quantity of dust-like seeds or spores, whence the species are commonly called Puff-balls. When the common Puff-ball, *Lycoperdon gemmatum*, first appears, it forms a whitish ball, looking like a common eatable mushroom, but by degrees it changes colour, becomes brown, and, tearing irregularly at the apex, discharges a cloud of brownish dust, consisting entirely of its spores. The Geasters, or Starry Puff-balls, are much less common; instead of bursting irregularly at the apex when ripe, their outer rind separates into a definite number of lobes, which spread open, curve backwards, and at last elevate upon their centre a bag containing the spores. No use has ever been made of any of the Lycoperdons, except in the case of *L. giganteum*, a very large indehiscent species, often many feet in circumference, and filled with a loathsome pulpy mass, which has been employed as a styptic, and for tinder.

LYCOPHRON, a native of Chalcis in Eubœa, was a poet and grammarian at the court of Ptolemæus Philadelphus, from B.C. 280 to B.C. 250, where he formed one of the seven poets known by the name of Pleias. He is said by Ovid to have been killed by an arrow.

Lycophron wrote a great number of tragedies, only one of which has come down to us, entitled 'Cassandra, or Alexandra.' This poem, however, cannot have any claims to be called a drama; Cassandra is the only person introduced as speaking. The work is written in iambic verse, and has no pretensions to any poetical merit; the style is very obscure, and the meaning of most passages is very doubtful.

LYCOPODIA/CEÆ, a natural order of vascular Acrogens, chiefly consisting of moss-like plants, inhabiting moors, boggy heaths, and woods in many parts of the world. They never exceed the height or length of two or three feet, and usually grow prostrate. Some of them, especially *Lycopodium catharticum*, are violent purgatives, and it has been proposed to use others as dyes; but in general they are of little importance to any except the botanical systematist. Their name has, however, of late been brought frequently before the public in popular works, in consequence of an opinion that certain large fossils common in the coal measures, and called *Lepidodendra*, are the relics of an extinct gigantic race of these now pigmy species. [COAL PLANTS.]

LYCOPODITES. The affinity of many fossil plants to some of the various genera composing the Lycopodiaceæ is very distinctly pointed out by M. Brongniart, both in the 'Prodrome' and in the 'Histoire des Végétaux Fossiles.'

LYCOPIDIUM, a fine yellow dust, the seed of the *Lycopodium clavatum*, or club moss. It is used for producing theatrical lightning, as it burns with a bright glare when ignited by a candle on spirits of wine. It is also sprinkled upon pills to prevent their adhesion. A decoction of the plant is used by the Poles as a remedy in the *plica Polonia*.

LYCOPUS EUROPEUS, a wild plant inhabiting wet ditches and sides of ponds, belonging to the natural order *Labiata*, and known popularly under the name of Gipsy-wort, because gipsies are said to stain their skins with its juice.

LYCURGUS. [SPARTA.]

LYCURGUS, the Athenian orator, the son of Lycophron, was one of the warmest supporters of the democratical party in the contest with Philip of Macedon. The time of his birth is uncertain, but he was older than Demosthenes. He is said to have received instruction from Plato and Isocrates. He took an active part in the management of public affairs, and was one of the Athenian ambassadors who succeeded (B.C. 343) in counteracting the designs of Philip against Ambracia and Peloponnesus. He filled the office of treasurer of the public revenue for three periods of five years, and was noted for the integrity and ability with which he discharged the duties of his office.

After the battle of Chæronea (B.C. 338) Lycurgus conducted the accusation against the Athenian general Lysicles. He was one of the orators demanded by Alexander after the destruction of Thebes, B.C. 335. He died about the year B.C. 323, and was buried in the Academia.

Only one of his orations has been preserved, an accusation of Leocrates, an Athenian citizen, delivered B.C. 330, for abandoning Athens after the battle of Chæronea, and settling in another Grecian state.

LYDD. [KENT.]

LYDGATE, JOHN, was a monk of the Benedictine Abbey of Bury St. Edmund in Suffolk. It has been conjectured that he was born about 1375. Warton says he seems to have arrived at his greatest eminence about the year 1430. He was eminently skilled in French and Italian, and wrote in English with great perspicuity. Ritson, in his 'Bibliographia Poetica,' has given a list of no fewer than two hundred and fifty-one pieces by Lydgate. His MS. of the 'Life of St. Edmund,' which he presented to Henry VI., is in the British Museum. It is conjectured that he died about 1461.

LYDIA, a country of Asia Minor, whose boundaries varied at different times. Under the Roman empire it was bounded on the S. by Caria, from which it was separated by the river Mæander; on the N. by a range of mountains named Sardene, which divided it from Mysia; on the E. by Phrygia; and on the W. by the Ægean, though the tract of country along the coast was more commonly called Ionia. Lydia was intersected by mountain ranges, running from east to west, of which the principal, called Més-sogis by Strabo, forms the northern boundary of the valley of the Mæander. Another chain of mountains, named Tmolus, runs parallel to the Més-sogis, and terminates on the west coast opposite the Island of Chios. A branch of Tmolus, called Sipylus, stretches more to the north-west, towards the towns of Cuma and Phocæa. Lydia is thus divided into two principal valleys; the southern, between Més-sogis and Tmolus, through which the Caystrus flows, is of moderate extent; but the northern, between Tmolus and Sardene, watered by the Hermus, and its tributaries the Hyllus, Pactólus, and Coganus, forms a considerable plain. The fertility of Lydia and the salubrity of the climate are frequently mentioned by

ancient writers. Chishull speaks of the country between Tmolus and Mésogis as a 'region inexpressibly delicious.'

According to Herodotus, the Lydians were of a common origin with the Carians and Mysians (i. 171).

The early history of Lydia is told by Herodotus (i. 6, &c.), who says that three dynasties ruled in Lydia: the Attyadæ, the Heraclidæ, and the Merminadæ, from B.C. 716 to 556. The proper history of Lydia begins with the last of these dynasties. The first king of this dynasty was Gyges, and the last was Croesus. The Lydian kingdom had its greatest extent during the reign of Croesus, who subdued all the people of Asia Minor west of the river Halys (Kizil-Ermak), with the exception of the Cilicians and Lycians. (Herodot., i. 28.) But this empire was overthrown by Cyrus (B.C. 556); and the country became a Persian province. After Alexander's conquests, Lydia, with the rest of Western Asia, formed part of the empire of the Seleucidæ; and on the conquest of Antiochus by the Romans, B.C. 189, it was given to Eumenes, king of Pergamus. On the death of Attalus III., B.C. 133, it came, with the other dominions of the kings of Pergamus, into the power of the Romans.

The Lydians carried on a large trade, and had abundance of the precious metals. The Lydians are said by the Greeks to have been the first people who put a stamp upon gold and silver.

The most extraordinary work of art in ancient Lydia was the enormous sepulchral mound of Alyattes, the father of Croesus. It was 1300 feet in width. [ALYATTES.]

The Grecian towns on the coast of Lydia belong to IONIA. The most important of those towns which properly belonged to Lydia were Sardis, Philadelphia, and Thyatira.

Sardis, called at present Sart, is situated on the Pactólus, a tributary of the Hermus, in an extensive plain. The citadel was situated on a hill, which was a perpendicular precipice on the back part, which looked towards Tmolus. Sardis was the capital of the Lydian kingdom, and the residence of the Persian satraps of the country. It was nearly destroyed by an earthquake in the time of Tiberius (Tacitus, 'Ann.,' ii. 47); but it was rebuilt. Sart is at present a miserable village; but there are large ruins of the ancient Sardis.

Philadelphia, called at present Allah Shehr (that is, 'City of God'), 28 miles south-east of Sardis, stands on a part of Mount Tmolus, by the river Coganus. To the east of Philadelphia Strabo places the district of Katakekaúmene, or 'Entirely burnt,' 500 stadia in length and 400 stadia in breadth. He describes the surface of the plain as covered with ashes, and the mountain rocks as of a black colour, as if they had been subject to the action of fire.

Thyatira, called at present Akhissar, was built by Seleucus Nicátor. It was famous for the art of dyeing purple. (Acts xvi. 14.) Thyatira, Philadelphia, and Sardis are three of the Seven Churches which are addressed in the Book of Revelations.

LYDIAN (from *Lydia*, a country of Asia Minor), an epithet applied by the Greeks to music which was of a tender and flowing character,

'Softly sweet, in Lydian measure,
Soon he soothed the soul to pleasure.'—DREYDEN.

The character of this poetry is said to have been striking and animated yet capable of pathos and melting softness; and it was on this account that Plato banished it from the republic. Some attribute its invention to Amphion; but Pindar states that it was first used at the marriage of Niobe.

LYDIAN STONE, the name of a silicious rock, of a grayish-black colour, a splintery or conchoidal fracture, and keen edge. It is sometimes named black jasper.

LYDUS, JOANNES LAURENTIUS, was born at Philadelphia in Lydia (whence he derived his surname), about 490. He died about the latter end of Justinian's reign. Lydus appears to have been well acquainted with Greek and Roman antiquities; and his works contain much curious information on the mythology and history of several of the nations of antiquity.

LYGODYSODEA'CEÆ, a natural order of plants closely allied to *Cinchonaceæ*. The only genus of this order is *Lygodysodea*, of which two species, *L. fetida* and *L. ciliata*, have been described. They are both natives of Peru and Mexico.

LYING-TO. A nautical term denoting the state of a ship when the sails are so disposed as to counteract each other, and thereby retard or destroy the progressive motion of the vessel.

LYLY, WILLIAM. [LILY.]

LYME REGIS. [DORSETSHIRE.]

LYMINGTON. [HAMPSHIRE.]

LYMPH, LYMPHATICS. The Lymphatics are the system of vessels which, from the part that they take in the process of absorption, are not unfrequently called absorbents. They consist of minute branched tubes of extremely delicate membranes, whose extremities are arranged in a more or less dense network in every part of the body. From this network they gradually converge into a succession of branches of increasing size, and terminate in two main trunks, called the right and left great lymphatic veins, through which the lymph is poured with the chyle from the thoracic duct [LACTEALS] into the right and left subclavian veins. The lymphatics also communicate with the veins at some other parts of their course, chiefly near their minute extremities, and more rarely by larger branches. They have in their interior numerous delicate valves formed of crescentic folds of the lining membrane, exactly like those of the veins, and, like them, preventing the retrograde force of the contained fluid.

The Lymph is a thin opaline whitish fluid of a somewhat saline taste, which a short time after it is removed from the body separates into a clear fluid and a soft white or pinkish coagulum.

The name of Lymph is rather vaguely applied to many different morbid secretions which have a thin watery appearance. Coagulating or coagulable lymph is the fibrinous matter effused in the adhesive inflammation.

LYNCH LAW, the rough species of justice sometimes administered in parts of the United States by the 'sovereign people,' and so called, it is said, from a Virginian farmer named Lynch, who, having caught a thief, bound him to a tree, and summarily flogged him.

LYNCHBURG. [VIRGINIA.]

LYNDHURST. A village in the centre of the

New Forest, Hampshire, 8 miles W.S.W. of Southampton, has only 1522 inhabitants, but contains the King's House, or official residence of the Lord Warden of the forest. All the forest courts are held here. In the vicinity is the spot where William Rufus is supposed to have been slain by Tyrrel's arrow.

LYNEDOCH, GENERAL, LORD, was born in 1750, and was the third son of Thomas Graham of Balgowan, in Perthshire. By the death of his two elder brothers he succeeded to the family estates. But on the loss of his wife, to whom he was devotedly attached, he was induced to take up the profession of arms; and in 1793 he accompanied Lord Hood, as a volunteer, with British troops to Toulon. He afterwards raised two battalions; and in a very few months the first battalion, the 90th, formed a part of the earl of Moira's army. Colonel Graham was afterwards attached to the Austrian army of Italy, and was beleaguered in Mantua with General Wurmser during the investment of that city. As yet he had had but few opportunities of distinguishing himself; but in 1808 he was allowed to accompany his friend Sir John Moore to Sweden, and afterwards to Spain; where in 1809 the sanguinary battle of Corunna was fought, in which Colonel Graham so distinguished himself, that he was immediately placed on the list of major-generals. He accompanied the British expedition to Walcheren and Flushing; but was compelled by the fever there prevalent to return to England. He was next ordered to Cadiz; and in 1811 a British force of 3000 men, commanded by him, and a body of 7000 Spaniards, were embarked in Cadiz Bay, in order to form a junction with the Spanish General St. Roche. The united forces, under General La Pena, took their position near Barossa, where a sanguinary battle was fought with the French troops under Marshal Victor. Such was the consummate skill and promptitude of General Graham in his attack, that in less than one hour and a half from the commencement of the action, the enemy were in full retreat, with a loss, in killed, wounded, and prisoners, of 3000 men. In the summer of the same year General Graham joined the army under Lord Wellington, and took an energetic part in the siege of Ciudad Rodrigo. Owing to a complaint in his eyes at this period, he was obliged to return to England to seek advice; but early in 1813 he again quitted England for the Peninsula; and in June of the same year was engaged in the battle of Vittoria, at which he commanded the left wing of the army under the marquis of Wellington, and not only defeated the enemy, but cut off their retreat by the highway to France. In the subsequent military affairs of the Peninsula, the name of Sir Thomas Graham was everywhere to be found, at San Sebastian, the Bidassoa, &c., until he succeeded in triumphantly entering on French ground. On his return to England he was appointed commander of the forces in Holland. After receiving the thanks of Parliament for his conduct in the Peninsula, he was raised to the peerage by the title of Baron Lynedoch, of Balgowan, co. Perth. In 1821 the governorship of Dumbarton Castle was conferred upon him. He died in 1844, aged ninety-four.

LYNN. [NORFOLK.]

LYNX. The name of *Lynx* is applied by zoologists to a subdivision of the feline group, regarded

by Dr. Gray in the light of a genus, to which he has applied the term *Lyncus*. [FELIDÆ.]

Cuvier observes that there are known in commerce, under the name of *Loups Cerviers* (*Lupus cervarius*), four or five sorts of Lynxes, which had long been confounded by naturalists, and whose specific limits were not perhaps well fixed when he wrote. We shall proceed to notice the arrangement of M. Temminck, and then return to observe what part of it is adopted by Cuvier.

M. Temminck gives the following as species:—

1. *Felis cervaria*, described as nearly equalling a wolf in size, and possibly the *Kattlo* of Linnæus and the Swedes; but it has been remarked that no skins of it are contained in the cargoes that arrive from the Baltic. In commerce the skins of *F. cervaria* are said to be only obtained from the markets of Moscow, to which they are brought from the provinces of Asia. It is considered as probable that this species may have been confounded, under the name of the *Canadian Lynx*, with

2. *F. borealis*, which is intermediate in size between the fox and the wolf. This comprehends the *Canadian* but not the *Mississippi Lynx* of Cuvier, and is said to inhabit the north of both the old and the new continents: its fur, less valuable than that of *F. cervaria*, is stated to be received equally from Sweden and from Hudson's Bay.

3. *F. Lynx* (true Lynx), different from, but nearly allied to, *F. cervaria*, *F. borealis*, *F. rufa*, and

4. *F. pardina*. Size of a badger, but the legs longer, resembling *F. rufa* in form and size; tail short, but longer in proportion than that of *F. Lynx*. *F. pardina* is the *Loup Cervier* of Perrault, and is found only in the south of Europe, the centre being the locality of the true Lynx.

5. *F. Caracal*, *Nubian Caracal*, and *Cat of the Desert of Bruce*, *Persian Cat* (*Lynx*) of Pennant.

6. *F. aurata*. Rather less than the Caracal. Country unknown. Skin purchased from a London dealer.

7. *F. Chaus* (Güldenstedt), figured by Schreber. The other animals described under this name are considered to be referrible to

8. *F. Caligata*; *Booted Lynx* of Bruce; *F. Libycus* (Olivier); *Libyan Caracal* of Buffon.

Of these, Baron Cuvier notices *Felis cervaria* as the finest and largest; *Felis borealis*; *Felis Lynx*, which has almost entirely disappeared from populous countries, but is still to be found in the Pyrenees, the mountains of the kingdom of Naples, and even, it is said, in Africa; *Felis pardina*, Oken, from the south of Europe; *Felis rufa*, Gülden.; and *Felis Chaus*, or *Lynx of the Marshes of Caucasus*, Persia, and Egypt. Cuvier further observes, that it is believed at present that the *Booted Lynx*, *Felis caligata*, Temm., may be distinguished from *Felis Chaus*; but he remarks that *F. caligata* is at least very nearly approximated to it, and that it has the same habits.

Felis Caracal (Persia, Turkey, &c.), which he considers to be the true Lynx of the ancients, closes Cuvier's list of species; but he alludes in a note to *Lynx faciatius*, *L. floridanus*, and *L. montanus* of Rafinesque, and to *Felis aurata* of Temminck, as belonging to this tribe.

M. Lesson gives the following species:—1. *F. Lynx*, the *Loup Cervier* of the Furriers. He states

that the whole of Europe is its habitat, where it has become very rare. 2. *F. pardina*, Temm., *Loup cervier* of the French Academicians; to this Portugal, Sardinia, Sicily, and Turkey are assigned as localities. Next follows *Felis Serval*, which cannot be considered a Lynx. 3. *F. cervaria*, Temm. 4. *Felis Borealis*, to which the northern countries of America and Asia are given as its distribution. 5. *Felis Caracal*, the Lynx of the ancients (Africa, Persia, and Arabia). 6. *F. chrysothrix* and *F. aurata*, Temm.; country unknown. 7 *F. Chaus*, Gülden. (Egypt, Nubia, and Caucasus). 8 *Booted*

Caracal (*Felis caracal*).

Lynx (*F. caligata*, Bruce, Temm.) To this a range is given from Egypt to the Cape of Good Hope in Africa, and the south of Asia. M. Lesson also notices as specifically different the *Felis Manul* of Pallas and Desmarest, a species not admitted by Temminck, but which has, according to Pallas, the appearance of the *Lynx*. (Mongolian Tartary.)

Sir William Jardine, who adopts the genus *Lynxus* or *Lynchus* of Mr. Gray, as the fifth genus of the *Feline*, enumerates the following species: *Lynchus Caracal*; *L. aurata*; *L. chelidogaster*, inhabits Chili (Temm., Mus. Leyd.); *L. caligata*, Bruce; *L. nigripes*, Burchell, inhabits South Africa; *L. Chaus* (Gülden., Rüpp.); *L. Canadensis*; *L. rufa*, Bay Lynx, inhabits banks of Columbia river, United States, not Canada (Temm.); *L. fasciata*, Banded Lynx (Richardson), inhabits N. America, woody countries in the neighbourhood of the Pacific (Lewis and Clark); and *L. Lynx*.

Sir William Jardine remarks, that there is yet considerable confusion among the Lynxes of America, and that, except the Canada Lynx, the species are perhaps not well determined. He observes that M. Vigors and Dr. Horsfield describe one under the title of *F. maculata* from Mexico.

Sir William further states that another Asiatic Lynx may be perhaps added in the *Felis affinis* of Mr. Gray, figured in his 'Illustr. of Indian Zoology.'

It may be necessary also to call the reader's attention to two species of *Felis*, *F. servalina*, figured as *F. ornata*, which Sir W. Jardine at first considered as identical with Mr. Gray's species with the last-mentioned name, but which Mr. Gray considered to be distinct. The figures of both *F. ornata*, Gray ('Illustr. Ind. Zool.'), and *F. servalina*, Jardine, have small tufts on the tips of their ears, and are otherwise inclined to be lynx-like, as if they formed

the passage between some of the smaller Spotted Cats and the Lynxes.

LYNX, a constellation of Hevelius, situated directly in front of Ursa Major, the head of the animal being halfway between a Ursæ Majoris and Capella.

LYON KING-AT-ARMS. This officer, who by the law of Scotland has sole power and jurisdiction in heraldic affairs, is said to derive his name from the lion rampant, the old armorial bearings of the Scottish kings, which he carries upon his robes. His jurisdiction is defined by various ancient statutes. He has power to visit the arms and ensigns-armorial of all noblemen and gentlemen throughout the kingdom, to give grants of arms to deserving persons, to matriculate them in his register, and to fine to the extent of 100*l.* Scots (8*l.* 6*s.* 8*d.* sterling) all persons who use arms without being matriculated. He further appoints all heralds, pursuivants, and messengers-at-arms. Much of his duties in former times was ministerial, and he still with his heralds makes proclamations of war and peace throughout the kingdom. There is an appeal from the decisions of the Lord Lyon to the Court of Session.

LYONS (the ancient *Lugdunum*), the capital of the department of Rhône, in France, is situated at the confluence of the Rhône and the Saône, in 45° 45' 45" N. lat., 4° 49' 10" E. long., 288 miles S.E. of Paris, and has 318,803 inhabitants. Lugdunum is said to have been founded by L. Munatius Plancus, who settled here a portion of the inhabitants of Vienna (Vienne), when driven from their homes by a revolt of the Allobroges, about 42 B.C. Strabo describes it as the most populous city of Gaul, except Narbonne (iv. 192, Casaub.) It was the great mart of the Romans, who had a mint here for coining gold and silver money; and it gave name to one of the four great divisions of Gaul. Lugdunum was utterly destroyed in a single night by fire, about A.D. 59, and was rebuilt chiefly by a grant from the Emperor Nero, to whom the citizens manifested their affection and fidelity in his downfall. In the beginning of the fifth century, the Burgundians possessed themselves of this town and of the south-eastern part of Gaul. On their overthrow it came into the power of the Franks. Lugdunum, during the Roman period, occupies a considerable place in ecclesiastical as well as in civil history. The Gospel had been early introduced into this part of Gaul, and here a severe persecution raged in the reign of Marcus Aurelius Antoninus, in 172 or 177. The churches at Vienna (Vienne) and Lugdunum sent a relation of their sufferings to those of Asia and Phrygia. Pothinus, bishop of Lyons, was one of the martyrs in this persecution. His successor was Irenæus, one of the most eminent of the early Fathers.

In the division of the Frankish kingdom under the Merovingian princes, Lyons, as we may now call it, was included in the kingdom of Bourgogne (561-613). In the division of the Frankish empire among the grandchildren of Charlemagne in 843, Lyons, with the district of Lyonnais, fell to the lot of the Emperor Lothaire; and in the subsequent division of his states in 855 it fell to Charles, king of Provence, who made it his usual residence. On his death in 863 it was seized by Charles the Bald, king of France. On the re-establishment of the kingdom

of Bourgogne by Boso in 879, Lyons was included in his dominions. In the troubled period of the later Carolingian kings, Lyons was subject alternately to them and to the kingdom of Bourgogne Transjurane. It was in these troubled times that the counts or governors of Lyons succeeded in establishing a hereditary sway over the districts of Lyonnais, Forez, and Beaujolais, but not over the city of Lyons, the lordship of which was obtained by Bouchard, archbishop of Lyons, and after his time remained annexed to the see. The archbishops, whose temporal power over the city was confirmed by the emperor in 1157, received the title of exarch: they were allowed free and independent jurisdiction, except so far as they were subject to the supreme authority of the emperor and the general laws of the empire.

About the middle of the thirteenth century, the citizens of Lyons became dissatisfied with the government of their ecclesiastical rulers; they elected a municipal body, between whom and the archbishop dissensions broke out, which led to the annexation of the city by Louis IX., the judicial administration remaining partly in the hands of the archbishop, partly in the municipality or consulate, as the civic council of Lyons was called. The citizens had the right to elect their own magistrates, and to control the receipts and outlay of the municipal officers; they were also exempt from the jurisdiction of any courts but those established in the city. Under this government the town increased in population, wealth, and commerce, till the sixteenth century, when it suffered much at the hands of the Huguenots, but recovered its prosperity in the seventeenth and eighteenth centuries. In the year 1793, during the government of the Convention, the people of Lyons rose against the tyranny of the revolutionary club which had been established in the city, and seizing the town-hall, put Challier, president of the club, to death. To avenge this affront, the Convention sent an army of 60,000 men with a hundred pieces of cannon. The town was bombarded, and obliged, after a siege of sixty-six days, to yield to famine and force; and during the cruelties that followed in the next five months nearly 6000 victims perished, including those who fell in the defence; the principal buildings were demolished, and a new name—*Commune Affranchie*—was given to the city. This dreadful blow, together with the long war which followed the French revolution, caused the commerce and manufactures of Lyons to languish. On the return of Napoleon from Elba, in 1815, his cause was espoused by the Lyonnese. In 1831 and 1834 Lyons was the scene of great disturbances, which originated in the disputes of the trades unions with the master manufacturers respecting wages, but had also connection with the republican party, who headed the insurrection, and were ready to make it subserve their own purposes. In the last-mentioned year, the insurgents by barricading the suburbs contested the possession of the town for two days with the military, but at the end of that time they laid down their arms. Numerous famous historical personages have been natives of this city: among them the Roman emperors, Claudius, Caracalla, and Marcus Aurelius; St. Ambrose, St. Irenæus, and Pope Clement VI.

The city of Lyons is very advantageously situated on the railway from Paris to Marseilles, and the

navigable rivers, the Rhône and the Saône, in the fork between which the greater part of the town is built. This part of Lyons consists mostly of narrow, crooked, dirty streets, formed by solidly built houses of seven or eight stories high. To afford room for the extension of the town southwards, the two rivers have been made to meet about a mile below their original junction, thus forming the peninsula of Perrache, on which the streets are built with more regularity and elegance, and some beautiful promenades are laid out. The old fortifications between the city and the hill and suburb of Croix-Rousse prevented the extension of the town northwards, but by a decree of the French republic, dated March, 1848, these fortifications were ordered to be demolished, and a wider enceinte to be constructed, so as to include this suburb, which was thence to be considered as an integral part of Lyons. A considerable part of the town lies on the right bank of the Saône, both shores of which are lined with quays. Here also is the steep hill and suburb of Fourvières on the south-west; and the suburbs of Serin and Vaize on the west. On the left bank of the Rhône are the suburbs of Brotteaux and Guillotière; its right bank is lined with quays throughout the whole length of the city, some of them being planted with trees and forming delightful promenades.

The suburbs of Fourvières and Croix-Rousse are chiefly inhabited by silk weavers. The hill of Fourvières is said to derive its name from *Forum-Vetus*, an ancient Roman structure which stood on its summit, and on the site of which the church of Notre-Dame is now built. The remains of an aqueduct and amphitheatre have been found on this hill. From the terrace close by this church, or from a tower erected near it, the view over the city of Lyons, its two noble rivers, its squares, chief structures, quays, avenues, and bridges, the hills and plains in the vicinity, of the snowy peak of Mont Blanc and the Alps of Dauphiné in the far distance, presents one of the most varied and most beautiful panoramas in Europe.

The Rhône, which runs along the eastern side of the town, flows with a rapid current 656 feet wide, and is spanned by four bridges, that unite the city to the populous suburbs of Guillotière and Brotteaux, which are protected from the inundations of the river by high embankments. The Saône flows in a gentle current with a breadth of 492 feet along the base of the hill Fourvières, a projecting crag of which formerly blocked up the passage along the right bank, but was cut through by the Romans, and hence it got the name of *Petra Excisa*, still remaining in the modern name *Pierre-Scise*. The Saône is crossed by nine bridges.

Of the fifty squares or open spaces in the city, the finest are—the Place-Bellecour, which is planted with lime-trees, and is one of the largest squares in Europe; and the Place-des-Terreaux, of which the town-hall and the Palais-des-Arts form two sides.

The public structures of Lyons are numerous, and with some exceptions more remarkable for solidity than elegance. These the space allowed for this article will permit merely to mention. Among the chief religious edifices are—the splendid cathedral of St.-Jean, on the right bank of the Saône, the churches of St.-Pierre, d'Ainai, de l'Observance, Notre-Dame-de-Fourvières before mentioned, St.-Nizier, St.-

Bonaventure, St.-Polycarpe, des-Chartreux, St.-Georges, St.-Irénée, and St.-Just. These, together with the palace of the archbishop, form a series of buildings interesting from their architecture, extent, decorations, and antiquity. Among the civic structures are the prefect's residence, once a Jacobin convent; the town-hall, the finest building of the kind in France; the court-house, on the Quai-de-la-Saône; the public library; the Palais-des-Arts, in which are an exchange, galleries of paintings and sculptures, cabinets of medals, collections of minerals and of natural history, specimens of silk manufactures, &c.; the Loge-du-Change, formerly an exchange, now a Calvinist temple; the college, situated on the Quai-du-Rhône; the mint; the general hospital, or Hotel-Dieu; the Maison-de-la-Charité, or asylum for the poor; the hospital de l'Antiquaille, built on the site of the Roman palace in which Claudius, Caligula, and Germanicus were born; the Mont-de-piété; the prisons; the two theatres; and the numerous barracks.

The fortifications of Lyons have been enlarged and strengthened under the imperial régime. Its environs are dotted with numerous country seats, gardens, and vineyards.

Lyons is an important manufacturing town. The staple articles of industrial produce are silk stuffs of all descriptions, which for solidity of texture, richness and permanence of dye, and beauty of design, are not equalled elsewhere. In this manufacture about 100,000 of the population are directly or indirectly concerned. Cashmere and silk shawls, ribands, cotton cloth, hosiery, hats, printed calico, jewellery, liqueurs, chemical products, gold and silver lace, crapes, tulle, glue, sheet lead, musical strings, ornamental paper, &c., are also made. There are, besides, numerous printing establishments, dye-houses, metal foundries, glass-works, potteries, tan-yards, breweries, boat-building yards, &c.

Lyons is also, from its advantageous position, a place of great commerce. The products imported into the town for its own consumption, or for re-exportation, are wine, brandy, oil, hemp, flax, soap, rice, chestnuts, salt, raw cotton, coffee, indigo, sulphur, lead, teazles, madder and other dye-stuffs, &c. Timber, firewood, building stone, and asphalt are the chief articles brought down the Rhône to this city. Down the Saône are brought timber of all kinds, oak staves, firewood, charcoal, tanning bark, iron and iron ore, gypsum, hay, straw, corn, building stone, bricks, tiles, &c. Steamers ply on the Saône to Châlon-sur-Saône, and on the Rhône to Avignon and Arles. The town has communication with the Rhine by the Canal-du-Rhône-au-Rhin; and with Paris by the Saône and the canals that join it to the Seine. A railroad, 35 miles in length, unites Lyons to the great manufacturing town of St.-Etienne and the extensive coal-fields of the department of Loire.

Lyons gives title to an archbishop, whose see includes the departments of Rhône and Loire. It is the seat of a high court (Cour Royale) and of a university academy, which have jurisdiction over the departments of Aine, Loire, and Rhône. Connected with the university there are in Lyons faculties of theology and the sciences, a secondary school of medicine, and a college; and within the jurisdiction six colleges, sixty-two boarding-schools, three primary normal schools, and 1470 day-schools. The city

has also a tribunal of first instance, a tribunal and chamber of commerce, a council of Prud'hommes, an academy of sciences and arts, a theological college, a school of the fine arts, a mint, an establishment for deaf-mutes, a school of arts and trades, besides various other literary, scientific, and benevolent institutions.

LYONNAIS, a former province of France, which now forms the departments of RHÔNE and LOIRE. Lyons was its capital.

LYONS, VICE-ADMIRAL LORD, was born at Barton, co. Hants, in 1790. He was educated at Westminster School; and in 1801 entered the royal navy. In 1804 he accompanied Admiral Duckworth's expedition to the Dardanelles; and proceeded to the East Indies in 1807. His various exploits stamped him as a true British sailor, and at the age of twenty he was appointed flag-lieutenant on board the *Minden* 74. While lying off the coast of Java he displayed consummate bravery by the capture of Fort Marrach; and in 1814 received post-rank. During the peace that followed he was employed in a variety of ways. In 1828 he commanded the *Blonde*, and entered the Black Sea, which was the first occasion on which a British man-of-war had ever done so. In 1835 he was knighted, and in 1840 made a baronet. His nomination, as second in command, of the Mediterranean fleet, in 1853, brought him from his embassy at Stockholm to commence that brilliant career which has rendered his name illustrious as a British seaman. In 1855, during the contest with Russia, he assumed the chief command of the Mediterranean fleet, on board the *Agamemnon*; when a series of victories, which are more matters of history than of biography, crowned his distinguished career. Kinburn fell, the fortress of Kertch was captured, and the attacks on the fortifications of Sebastopol were skilfully conducted. In 1856 he was created a British peer; and in 1857 he became vice-admiral of the White. He died at Arundel Castle, Sussex, the seat of his son-in-law, the duke of Norfolk, in November, 1858.

LYRA (the Harp), one of the forty-eight constellations of Pompey, representing the lyre of Mercury (Aratus), of Mercury or of Orpheus (Hyginus). It is surrounded by Cygnus, Aquila, Hercules, and the head of Draco. Its brightest star, α Lyre, also called Vega, is a conspicuous object. If a line be drawn through the middle of Cassiopeia, the pole-star, and the middle of Ursa Major, this star may be seen nearly in the perpendicular to that line drawn through the pole-star. When Aquila is known, a line drawn through its four neighbouring stars, δ , θ , β , α , and γ , will pass through α Lyre.

LYRE (*λύρα*), a musical instrument of the stringed kind, known under various names from the earliest historical period. Some of the Greeks ascribe its invention to Hermes, some to Hyperion; but it is possible that they may have had it from the Egyptians, and the Egyptians from Asia. Of many instruments figured or described in early writings, it is difficult to decide whether they should be termed lyres, lutes, harps, or guitars. The most ancient Grecian lyre had only three strings. That of Terpander had seven. Timotheus increased the number to eleven; and others were gradually added, till they reached sixteen, fifteen of which rendered the principal sounds in the Greek scale, and the sixteenth was

the *Proslambanomenos*, an additional or supernumerary sound.

LYRE BIRD. [MÆNURA.]

LYRIC POETRY is commonly understood to be that kind of poetry which is composed in order to musical recitation; but the epithet has been transferred to all kinds of verse partaking in any degree of the same nature as that to which it was first applied. Thus we hear of lyrical ballads, the greater part of which might with as great propriety be called epical, and of lyric measures in Horace where there is no ground to suppose that they were sung, and no fitness for the purpose of musical rehearsal. In a former article [EPIC POETRY] a distinction has been made between epic and lyric poetry more satisfactory than common language allows. There is no impropriety in giving a decided meaning to words which have usually been understood in a confused sense, particularly when, as in the present case, the same senses have been applied to each, so as not only to confuse, but to confound them. Lyric poetry may, then, be defined as that class of poetry which has reference to and is engaged in delineating the composer's own thoughts and feelings, in distinction from epic poetry, which details external circumstances and events. The former is therefore called *subjective*, and the latter *objective*.

LYS. [BELGIUM; SCHELDT.]

LYSANDER, a Spartan, who rose to eminence towards the end of the Peloponnesian war, and was placed in command of the Lacedæmonian troops on the coast of Asia Minor, B.C. 407. Unlike most of his countrymen he had great flexibility of character, and gained the regard and confidence of his Persian allies. During his year's command he defeated the Athenian fleet, commanded by Antiochus, as lieutenant of Alcibiades, at Notium. In September, 406, he was superseded by Callicratidas, who was defeated and slain in the memorable battle of Arginusæ. The allies petitioned that Lysander might be reappointed; and having resumed the command, he gained the decisive victory of Ægospótami, in the Hellespont, where 170 Athenian ships were taken. This in effect terminated the Peloponnesian war.

He accompanied Agesilaus during his first campaign in Asia, where his popularity and renown threw his superior into the shade; and an estrangement resulted, in which Lysander behaved with temper and wisdom. About B.C. 396 he returned to Sparta. In the following year, on occasion of a quarrel with Thebes, he was sent into Phocis to collect contingents from the northern allies. Having done this, and being on his way to join the Lacedæmonian army, he was taken by surprise, and slain by the Thebans, at Haliartus in Bœotia.

LYSIAS, one of the ten Athenian orators, was born at Athens, B.C. 458. At the age of fifteen he went to Thurii, in Italy, where he remained for thirty-two years. He returned to Athens, B.C. 411, and carried on, in partnership with his brother Polemarchus, an extensive manufactory of shields. Their wealth excited the cupidity of the Thirty Tyrants; their property was seized, and Polemarchus was taken to prison, where he was shortly after executed. Lysias escaped to Mégara, and died about B.C. 378. Thirty-four extant orations are attributed to Lysias.

LYSIMACHIA, a genus of plants belonging to

the natural order *Primulaceæ*. *L. thyrsoflora* is found in marshes in the north of England. *L. vulgaris* is the *L. punctata* of some botanists.

LYSIMACHUS, one of the officers of Alexander the Great, was born of an illustrious Macedonian family. In the distribution of the provinces to the chief Macedonian officers after the death of Alexander, Lysimachus received Thrace and the neighbouring countries. In B.C. 314 he joined Cassander, Ptolemæus, and Seleucus, in opposing Antigonus. [ANTIGONUS.] The peace, which was made between the contending parties, B.C. 311, lasted only for a short time. The conquests of Demetrius, the son of Antigonus, in Greece, roused the confederates to more vigorous exertions; and Lysimachus was sent into Asia Minor, B.C. 302, where he took several places, and acquired immense plunder. In the following year Lysimachus, having joined Seleucus, defeated and killed Antigonus at Ipsus in Phrygia.

Lysimachus obtained the north-western part of Asia Minor as his share of the captured country. He shortly afterwards married Arsinoe, the sister of Ptolemæus, king of Egypt, although his eldest son Agathocles had already married Lysandra, the half-sister of Arsinoe. In B.C. 286 he obtained possession of the throne of Macedon. The latter part of his life was embittered by family dissensions. Arsinoe, fearful lest her children should be exposed after the death of her husband to the violence of Agathocles, persuaded Lysimachus to put him to death. Lysandra, his widow, fled to Babylon, and entreated Seleucus to make war against Lysimachus, who, anticipating his intentions, marched into Asia, and fell in a battle with the forces of Seleucus, in his seventieth year.

LYTHRACEÆ, a natural order of polypetalous Exogens. They are most near *Melastomaceæ* and *Onagraceæ*. The order contains few plants of any interest.

LYTHRUM, a genus of plants belonging to the natural order *Lythroriaceæ*. *L. Salicaria*, Purple Loosestrife, is a native of Europe, in ditches and watery places, especially about the margins of ponds and rivers, and is found in Britain very plentifully. The colour of the flowers varies from crimson to purple. The herbage is generally almost smooth, and of a dark green, but in dry situations it becomes hoary and downy, or in some degree hairy, as well as more dwarfed in stature. This species is the *Lysimachia* of Pliny, lib. xxv. cap. 7; lib. xxvi. cap. 12, 14. *L. hyssopifolia* is found in damp places in Great Britain. *L. Hunteri*, Hunter's Purple Loosestrife, is a native of the East Indies, where it is used in dyeing.

LYTTELTON, GEORGE, LORD, born in January, 1708–9, the eldest son of Sir Thomas Lyttelton, Bart. He entered Parliament in 1730, and connected himself with the leaders of the opposition to Sir Robert Walpole. After Walpole's retirement Lyttelton was made a lord of the treasury, in 1744. He was raised in 1756 to be chancellor of the exchequer. He went out of office altogether in 1759, when he was raised to the peerage by the title of Baron Lyttelton of Frankley. The rest of his life was chiefly devoted to literature. He died in 1773.

Lord Lyttelton's literary talents are well known. His most important works are a 'History of Henry II.' and 'Observations on the Conversion and Apostleship of St. Paul.'

M.

M is the labial letter of the liquid series.

1. *M* is interchanged with *n*. Thus *m*, at the end of Latin cases and tenses, is generally represented by an *n* in Greek. Similarly the German dative *ihm* and accusative *ihn* have been confounded in the English *him*, which is at once dative and accusative. The German *boden*, *busen*, *besen*, *faden*, are in English, *bottom*, *bosom*, *besom* or *broom*, *fathom*.

2. *M* with *b*. Thus in Latin *hiemps* coexists with *hibernus*, *tumeo* with *tuber*, *glomus* with *globus*, *fama* with *fabula*. In our own language *husband* is a corruption of *house-man*, the correlative of *housewife*.

3. *M* with *p*. Hence the Greek forms *ορμα*, *τιτυμμα*, &c., for *ορμα*, *τιτυμμα*, &c. The Greek *μολυβδος* is in Latin *plumbum*.

4. *M* with *v*. This is particularly the case in the Welsh language. The Latin *amnis* is believed to be identical with the Welsh *Afon*, pronounced *Avon*. The Latin language has *promulgare*, apparently for *proulgare*. Compare also *himmel*, *heaven*; *immer*, *ever*.

5. *M* with *w* probably. This interchange follows easily from the last, and is a natural step towards the next. The German *mit* seems to be identical with our own *with*, and their longer preposition *wider* is to *mit* or *with* precisely as the Latin *contra* to *con*. The difference of meaning is only apparent, for the notion of hostility is secondary, and belongs to the shorter as well as to the longer forms. Thus in Latin we say *pugnare tecum*, and in English to *withstand*.

6. *M* disappearing. This appears to have been the case even at the beginning of words. Compare the Greek *μυρις* with *αχρ*, *μολυβδος* with *ολυβ*, the Latin *manus* with the Teutonic *hand*, the Latin *mere-re* with the English *earn*. At the end of words at least, the loss of an *m* is very common, particularly after *o*. Thus the Greek and Latin verb often has the first person ending in *o*, where analogy would lead to *om*; *scribo*, *τιπτω*. Compare the words *sum*, *inquam*, besides the other tenses *scribebam*, *scribam*. In Latin all the adverbs ending in *o*, signifying *motion to*, appear to have lost an *m*, viz., *quo*, *eo*, &c. Hence *adeo*, *quoad*, occur in conjunction with a preposition which elsewhere requires an accusative. Again, an *m* has been lost in *postea*, *antea*, *postillā*, &c.; compare *postquam*, *antequam*, &c.

7. *M*, like the other liquids, but not so frequently, is liable to change its position with regard to the vowel of a root. Thus in Greek the root *τιμ*, 'cut,' may take the form *την*.

MAAS. [BELGIUM; HOLLAND.]

MAASTRICHT. [LIMBURG.]

MABILLON, JEAN, born in 1632, became a Benedictine of the congregation of St. Maur in 1654, and died in 1707. His 'Museum Italicum,' 1689,

MACACUS.

and 'Iter Germanicum,' are full of learned matter: his controversial works, such as his 'Traité des Études Monastiques,' 1691, directed against De Rancé and the monks of La Trappe, were highly popular; and his 'Veterum Scripturarum varia Specimina,' &c., is still much esteemed. He was employed by Louis XIV. to collect books, and is described as one of the most learned and liberal men of his age.

MABLY, ABBÉ DE, born at Grenoble in 1709, died in 1785. His political works, which are numerous, are esteemed more for the facts they contain than for their arguments. The principal of them are—'De la Manière d'écrire l'Histoire,' 'De l'Étude de l'Histoire,' 'Observations sur l'Histoire de France,' 2 vols. 12mo, 1765, with a posthumous continuation in two more volumes, published in 1790.

MABUSE, or MAUBEUGE, JOHN. This eminent painter, whose proper name was John Gossaert, was born at Maubeuge in Hainault, in 1470, according to some authorities; in 1499, according to others. The finest specimen of this painter, perhaps, is the Wise Men's Offering, now at Castle Howard, the seat of the earl of Carlisle. He painted chiefly scriptural subjects, but was employed by Henry VII. to paint portraits of his children. The picture is at Hampton Court, and contains Prince Arthur, Prince Henry (Henry VIII.), and Princess Margaret. He died, it is said, in 1562, but it is not known where.

MAC or M', the Gaelic word for son. It is often used as a prefix to Scotch names, but in many cases it has of late years become incorporated with the name itself, as in Mackenzie, Macintosh, and Macpherson. It is probably allied to the Gothic word *magus*, 'a son,' 'a boy,' and its root is generally believed to be the Sanscrit *mah*, 'to grow.'

MACA'CUS (French, *Macaque*), a barbarous word adopted as the title of a genus of *Simiade* (Monkeys) peculiar to India and the Indian Islands.

In the *Macaci* or *Macaques* the body is stouter than in the *Guenons* [*GUENONS*], the head larger in proportion, the limbs more muscular, and the tail shorter. The muzzle is heavy; the superiliary is boldly prominent, and the forehead is flattened; the callosities are large, and mostly surrounded by a space of naked skin. There are ample cheek-pouches, and Cuvier states that a laryngeal sac is always present. The last molar of the lower jaw has a fifth tubercle, and the molars are broad. The tail is variable; in some species it is of considerable length, and these, in general form, approximate towards the *Guenons* (*Cercopithec*). In others the tail is short and slender; the ears are angular. The *Macaci*, like the *Guenons* of Africa, which they seem to represent, inhabit the forests, living in troops, and are remarkable for boldness and activity. Emboldened by tolerance, they become very audacious, pillaging

the gardens and the fields of grain; and their rapacity is seconded by address and cunning.

Cuvier says, relative to the Magot or Barbary Ape (genus *Inuus*), that it is simply a Macaque with a small tubercle in place of a tail. We regard the Magot as a form intervening between the Macaques and the Cynocephali, but still as a sub-genus of the latter group.

Wanderoo (*Macacus silenus*).

As examples of the genus *Macacus*, we may adduce the Toque or radiated Macaque (*Macacus radiatus*), the *Bonnet Chinois* of Buffon; the Rhesus (*Macacus Rhesus*); and the Wanderoo (*M. Silenus*), a native of Malabar and Ceylon.

MACAO, a Portuguese possession in China, situated at the southern extremity of the estuary of the Choo Kiang, or Canton River, $22^{\circ} 24' N.$ lat., $113^{\circ} 30' E.$ long, about 80 miles from Canton by the river. The population is estimated at 35,000, of whom about 30,000 are Chinese; the others are Portuguese, Hestizos or mongrels, English, Americans, &c. The town is built on a peninsula of the island of Heong-shan, which is $2\frac{1}{2}$ miles in length, by less than a mile in breadth, and is connected with the island by a narrow, low, and sandy isthmus, forming a land-locked inner harbour 12 miles in circuit.

Macao itself stands on several declivities, the shore being lined on the outer side by an embanked parade and a terrace of white houses, above which Chinese and European residences are curiously intermingled; but the mass of buildings, chiefly Chinese, are on an inner slope. Both harbours are within the vortex of typhoons, and suffer greatly from them. The climate is, however, very salubrious, and during the monopoly of the East India Company it was a favourite place of resort for Englishmen from India. The principal edifices are—the collegiate church of St. Joseph, eleven other churches, a convent, hospital, barracks, and the senate house, besides some Chinese temples. Six forts defend the harbour north and west of the town, which is fit only for small vessels. Large ships anchor in a roadstead east of the island. The trade of Macao was formerly restricted to the Portuguese and Spanish shipping, but now it is chiefly English and American, and that limited to twelve or fifteen ships annually, of from 4000 to

5000 tons, laden with tea and silk brought from the interior. The settlement has no export product itself, and its customs revenue rarely exceeds 20,000*l.* per annum, half of which is raised from the duty on opium; while the expenditure exceeds 32,000*l.*, so that it is a burden on the parent state. After the rise of Hong Kong, the commerce of Macao almost entirely disappeared, but it has since been made a free port, and great efforts have been made to restore its former prosperity. The educational wants of the inhabitants are provided for by the college of St. Joseph, a royal grammar-school, and female orphan asylum. The Portuguese authorities and others form a senate, a governor, and council, but the government of the native population is substantially vested in a Chinese mandarin.

Macao was granted to the Portuguese, subject to an annual rent, by the Chinese emperor in 1586, in return for assistance against pirates. In 1863 the payment of this tribute was rescinded, and the land conceded by treaty to Portugal; but jurisdiction over the Chinese inhabitants was retained.

MACARONI, a food product made of wheat flour in the shape of pipes. The manufacture is carried on chiefly in Italy (it was formerly peculiar to Genoa alone), but also at Marseilles and one or two other places in the south of France. *Vermicelli* is made of the same material, but in smaller rolls. Only the hard sorts of wheat, which contain a large proportion of gluten, are applicable to the manufacture. It is first ground into a coarse meal, and the bran being removed, it is called *Semola*. The flour is then worked up into dough with water, and forced through gauges, as in pipe-drawing, according to the size required. For the *Italian pastes* which are now so much used for soups, the dough is simply rolled out into thin sheets and cut into various shapes by means of stamps. Macaroni is now much used in England for puddings (if it is made of the best wheat it should swell considerably, and become quite soft, but not break or burst in boiling), and also for making a favourite dish of macaroni and cheese. The total quantity imported in 1864 was 7896 cwt., valued at 17,763*l.*, or rather over 2*l.* per cwt. The customs duty is the same as on flour, $4\frac{1}{2}d.$ per cwt.

MACARTNEY COCK. [PHEASANT.]

MACARTNEY, GEORGE MACARTNEY, EARL OF, was born near Belfast, May 14, 1787. He was educated at Trinity College, Dublin, and in 1759 entered himself at the Middle Temple, London. In 1764, through the interest of Lord Holland, he was despatched as envoy extraordinary to the empress of Russia, for the purpose of effecting a commercial treaty with that country, which he brought to a satisfactory conclusion, and returned to England in June, 1767.

In 1768 he was returned to Parliament, first for Cockermonth, in the English House of Commons, and afterwards for Armagh, in the Irish, and was appointed to the office of chief secretary for Ireland, January 1, 1769. As a debater, Macartney distinguished himself in the House against Flood, Dr. Lucas, and other leaders of the opposition. He held his office till June, 1772. In 1775 he was created an Irish baron, and made governor of Granada, where in 1779 he was compelled to surrender to Count d'Estaing, and was sent prisoner to France, but very

soon exchanged. In 1780 he was appointed governor of Madras, returning to England in January, 1786. In 1792 he was selected to undertake the embassy to Peking, in which service he gave so much satisfaction that he was elevated to an Irish earldom. In 1796 he was created Baron Macartney in the British peerage, and sent as governor of the newly-acquired territory of the Cape of Good Hope. He returned to England in 1798, and died on the 31st of March, 1806.

MACASSAR. [CELEBES.]

MACAULAY, CATHARINE, was born in 1733, and died in 1791. She was a most voluminous writer in defence of republican principles, and is chiefly known by her 'History of England from the Accession of James I. to the Elevation of the House of Hanover,' of which the first volume appeared in 1763, and the fifth in 1771, which, however, only came down to the Restoration. A sixth volume carried it on to the termination of Walpole's administration in 1742. Though the work went through more than one edition, it has now sunk into oblivion.

MACAULAY, THOMAS BABINGTON, LORD MACAULAY. It has often been remarked that the life of a man of letters presents few romantic or stirring incidents; is unmarked by those great events which illuminate the biographic page dedicated to the memory of successful statesmen or eminent warriors. The career of Thomas Babington Macaulay presents no exception to this general rule. Blessed with ample competence, with troops of friends, with an honourable position, he pursued the even tenor of his way undisturbed by external influences or an 'o'erleaping ambition,' and devoted his vast intellectual powers to the acquisition and diffusion of that knowledge in which his soul delighted. From his youth he was distinguished by an extraordinary capacity, a retentive memory, an insatiable greed of information, and brilliant conversational powers; and there were not wanting many eminent authorities and competent judges to predict his future fame from his youthful promise. His mind was early matured. The same exquisite polish, the same pictorial power, the same felicity in grouping illustrative facts about a particular topic, the same moderate liberalism of thought, the same qualities of trenchant sarcasm and well-weighed criticism, are visible in the productions of his student days as in the compositions of his more matured manhood, and the dazzling historical essayist of the *Edinburgh Review* is plainly conspicuous in the contributor to *Knight's Quarterly Magazine*. Macaulay was not one of those writers who attain completeness by slow degrees, by years of painful labour; his lucid intellect was ripe and perfect at the very outset of his career, and he sprang into fame and influence almost at a bound.

Macaulay was born in 1800 at Rothley Temple, in Leicestershire. He was the son of Zachary Macaulay, a wealthy merchant, whose indefatigable devotion to the cause of the emancipation of the negro was rewarded after his death by a tomb in Westminster Abbey. After the usual course of instruction under a private tutor, he was sent to Trinity College, Cambridge, where his remarkable mental powers immediately attracted notice, and he carried off all the honours open to the laborious student. Destined for the law, he was next entered

at Lincoln's Inn. He relieved the aridity of his legal studies by cultivating the muse, and contributed to a new periodical of great talent, *Knight's Quarterly Magazine*, some poetical compositions of peculiar merit, among which we may specially notice the 'Spanish Armada' and the 'Battle of Ivry.' These are distinguished by a curious felicity of language and a rare energy and fire. In 1826 he was called to the bar, but he thenceforth virtually abandoned the legal profession.

In the preceding year (1825) his essay on Milton had appeared in the *Edinburgh Review*. Its brilliant style, solid criticism, and extensive information produced an instantaneous impression that a new and superior luminary had risen upon the literary horizon. This essay was the first of a series, the most remarkable, perhaps, in our language, which was continued for fifteen years with constantly increasing excellence. In 1848 an incorrect edition having been published at Philadelphia without his authority, he decided on issuing a selection under his immediate auspices, and published it in three volumes, under the title of 'Critical and Historical Essays.' They attained a permanent popularity in this form, and find a place in every student's library. The most able and interesting are the essays on Milton, Addison, Hallam, Pitt, Bacon, Byron, Chatham, Frederick the Great, Johnson, and Gladstone. Apart from their dazzling style and extensive erudition, they were remarkable from the light they threw upon historical events and illustrious men, for their originality of view and independence of thought.

A warm partizan of pure Whig principles, which colour all his writings and influence his estimates of the men and deeds of the past, he was called at a comparatively early age to play an important part in the political world. He entered Parliament in 1830 as member for Calne, and participated in the violent debates which attended the introduction of the celebrated Reform Bill. His speeches were characterized by forcible reasoning and felicitous illustration, and he defended Earl Grey's measures with so much vigour and effect, that he was offered the secretaryship of the Board of Control. In 1832 he was returned to the reformed House of Commons for the important borough of Leeds. Two years later he resigned his seat to proceed on a mission to Calcutta, where, as member of the Council and President of the Legislative Council (1834), he carried out numerous reforms in the Indian laws. In the face of a bitter and unscrupulous opposition, he passed an Act which submitted to the jurisdiction of the local courts the civil affairs of the English scattered throughout India, and consolidated various heterogeneous statutes into a harmonious whole, which is still known as the Macaulay Code.

While in India he collected the materials for his two fine contributions to Anglo-Indian history, the lives of Lord Clive and Warren Hastings. These display in an eminent degree all the peculiar merits of his style, and the power which he possessed of placing before the reader a picture equally distinguished by accuracy of detail, force of outline, and depth of colouring. Some passages seem to us superior to the most elaborate episodes in his English History.

Soon after his return to England (1839) Lord

Melbourne conferred upon him the post of secretary at war, which he held until the downfall of the Whig ministry in 1841. In 1840 he had been returned to Parliament by the electors of Edinburgh. He continued to represent the Scottish capital until 1847, when he was unseated on account of the liberal vote which he had given in favour of the Maynooth College Endowment. Scotch Presbyterianism could not pardon this exercise of independent thought, even in a man who had rendered such distinguished services to the great cause of civil and religious freedom. Macaulay was keenly sensible of the injustice done him, and retired from a parliamentary career to devote himself to his favourite studies. But at the instance of Lord John Russell he returned to public life, and from 1846 to 1848 held the office of quartermaster-general, with a seat in the Privy Council. In the latter year he was unanimously elected Lord Rector of the Glasgow University.

Notwithstanding his parliamentary and official labours, Macaulay had found time to prepare the great work which has made his name European, and placed him, *longo intervallo*, at the head of British historians. Our readers will remember the furore produced in 1848 by the appearance of the first volumes of his 'History of England from the Accession of James II. ;' how they were sought for at the circulating libraries as eagerly as a sensation novel; how ladies pronounced them to be more interesting than the most interesting romance; and how critics stood astonished by their originality of view, elaborateness of treatment, pictorial effect, and amazing erudition. They could not but recognize, with unwonted unanimity, the historian's profound knowledge of the most recondite authorities; his singular photographic power of sketching characters, manners, and historical events; his faculty of comprehending the tone and spirit of the age he delineated; and his vivid yet dignified style. Blending in his narrative traits, pictures, allusions, biographical sketches, and even classical quotations, he troubled himself but little, as he said in his preface, about what is called the dignity of history, so long as he succeeded in conveying to his readers an exact knowledge of the public and private life of their ancestors. Nor did he pretend to absolute impartiality. He could not but profess for the heroes of liberty, for the patriots who had bled and suffered that England's freedom might be established on an eternal basis, that earnest admiration which he felt, and he lauded their achievements as warmly as he denounced the tyranny or bigotry of their oppressors. His History, therefore, has not escaped the attacks of political critics, and Tory writers have laboured to impugn many of his conclusions. It cannot be said, however, that he has been convicted of misrepresentation except in two instances; and even his warmest admirers must admit that he has failed to do justice to the memory and fame of William Penn and John duke of Marlborough.

We may here enumerate the various honours which showed the public appreciation of the historian's genius. He was Lord Rector, as already stated, of the University of Glasgow in 1848; Trustee of the British Museum, 1847; Fellow of the Royal Society, November, 1849; Foreign Member of the French Academy, May, 1857, and of the Prussian Order of

Merit in the same year; High Steward of Cambridge, 1857. In the latter year he was raised to the peerage, a tribute, it has been said, to his high and blameless character and transcendent literary distinction, and an act of royal favour quite unexpected, but highly approved by all whose approbation was of real value. It may be added that though he took his seat in the House of Peers, he never spoke in that 'august assembly.'

The gradual decline of his health, and the immense research necessitated by an historical work conducted on such novel principles and laid out on so elaborate a scale, prevented Macaulay from continuing his enterprise with any great rapidity. It was not until 1855 that the third and fourth volumes of his History appeared, and these only carried the reader down to the peace of Ryswick in 1697.

His last literary labour was the composition of some biographies for a new edition of the 'Encyclopædia Britannica.' These include Atterbury, Johnson, and William Pitt, and are distinguished by all his peculiar merits.

Lord Macaulay was never married. Yet was he a man of strong domestic affections, and he lavished a wealth of love on the children of his sister, Lady Trevelyan. He was a warm friend and a generous opponent, and it may be truthfully said of him that in all his political life he excited no lasting enmity.

His last years were harassed by the distressing symptoms of pulmonary disease, and his friends and admirers saw with deep regret that there was little chance of his living to complete the colossal work on which, as on a monument more enduring than brass—*monumentum ære perennius*—he had hoped to establish the superstructure of an enduring fame. Yet his end, when it came, came suddenly and unexpectedly. He fell asleep, as tranquilly as he had lived, on the 28th of December, 1859, in the sixtieth year of his age; and English literature was prematurely deprived of one of its greatest glories. On the 9th of the following January his remains were honoured with interment in Westminster Abbey, where they lie, in Poet's Corner, at the foot of Addison's statue, near to Johnson, and among many others of our most famous statesmen, poets, and men of letters.

Something must now be said of Macaulay as a conversationalist, and we shall avail ourselves of the opinions of the dean of St. Paul's, no incompetent judge. There is a common impression that in society he was engrossing and overpowering. Every one has heard the witty saying of his old friend, Sydney Smith (no two men could appreciate each other more highly or more justly), about 'flashes of silence.' But in the quiet intercourse with a single friend, no great talker was more free, easy, and genial than Macaulay. There was the most equable interchange of thought; he listened with as much courtesy as he spoke with gentle and pleasant persuasiveness. In a larger circle, such as he delighted to meet and assemble around him to the close of his life, a few chosen intimates, some accomplished ladies, foreigners of the highest distinction, who were eager to make his acquaintance, his manners were frank and open. In conversation in such a circle, a commanding voice, high animal spirits, unrivalled quickness of apprehension, a flow of language as rapid as inexhaustible,

gave him perhaps a larger share, but a share which few were not delighted to yield up to him. His thoughts were like lightning, and clothed themselves at once in words. While other men were thinking what they should say, and how they should say it, Macaulay had said it all, and a great deal more. And the stores upon which his memory could draw seemed inexhaustible. A wide range of Greek and Latin history and literature, English, French, Italian, Spanish; of German he had not so full a stock, but he knew the best works of the best authors; Dutch he learned for the purpose of his History. With these came anecdote, touches of character, drollery, fun, excellent stories excellently told. The hearer often longed for Macaulay's memory to carry off what he heard in a single morning, in an after-dinner colloquy, or in a few hours in a country house.

With respect to Macaulay as an essayist a few observations may be permissible. His style was eminently individual, and its leading features were vigour and animation, copiousness, clearness, and above all, English, 'pure and undefiled'—the English of Addison, Steele, and Burke, enriched by his own copious imagination, and enlivened by a vivid poetic faculty. He was so strong, and so conscious of his strength, that sometimes he underrated the force of his own expressions. No ornament, however, is introduced for the sake of ornament; Macaulay's is the style of a Homeric hero, not of an Oriental potentate. Its lucidness is wonderful; no sentence need be read twice before you can apprehend its meaning. And not less wonderful is its pictorial power; it flashes upon the mind a series of brilliant pictures, each complete in detail and vivid in colouring, so that one feels as if walking through a picture gallery crowded with the masterpieces of a great artist.

As a poet, Macaulay's fame will rest on his 'Days of Ancient Rome,' his 'Armada,' 'Ivry,' 'Naseby,' and 'Moncontour.' In other departments of poetry he would probably have failed through his very affluence and prodigality; his prize poems and some of his early writings show that, like Tarpeia, the weight of his golden spoils would have crushed him. But the essence of the ballad, as an accomplished critic remarks, is simplicity—simplicity not inconsistent with the richest word-painting. The *vivida vis*—the life, force, movement—conspicuous in all Macaulay's writings, are displayed in his ballads with singular success, so that in English literature, and in their own peculiar line, they are unrivalled. They have called forth a host of imitations, but none have even approached their excellence. It must not, however, be supposed that Macaulay was a poet in the higher sense of the word; but he possessed the *poetic faculty*, and it is this which enhances the rare and surpassing merits of his prose.

No complete biography of this illustrious man of letters has yet appeared, but a brief sketch is prefixed to the eighth volume of the octavo edition of his History. See also Mr. Arnold's *Public Life of Lord Macaulay*; the preface, by Mr. Adam Black, to the biographies of Pitt, Atterbury, and Johnson; the *Imperial Dictionary of Biography*; the *Annual Register*; and the notices in *Blackwood*, *Fraser*, and other magazines, in January and February, 1860.

MACAW. [PSITTACIDÆ.]

MACAW-PALM, a genus of palms, the *Acrocomia sclerocarpa* of the West Indies. It comprehends a portion of those majestic species of palms which soar to the height of forty or fifty feet; and from their gigantic foliage and towering stems impart features of grandeur to the surrounding country. The fruit yields an oil of a golden yellow colour, of the consistence of butter, which has a sweetish taste, and emits an odour like violets. The nuts are sometimes fancifully carved by the natives, and highly polished.

MACBETH, or MACBEATHAD MAC FIN-LEGH, as the chroniclers call him, whose stormy career and terrible crimes have been immortalized by Shakspeare in a tragedy which is, perhaps, only second to 'Hamlet' as a work of the highest genius, was *maormor*, or ruler, of the province of Moray, and succeeded the 'gracious Duncan' as king of Scotland, on Duncan's defeat and death in battle, near Elgin, in 1039. In his administration he displayed great energy, no ordinary ability, and a fervent love of justice; but the partizans of the Duncan dynasty rose against him, and, assisted by Siward, the Danish earl of Northumbria, and Macduff, the *maormor* of Fife, defeated him at Dunsinane Hill in Perthshire, in 1054. It was not on this occasion, however, nor by the hand of Macduff, the man 'not of woman born,' that Macbeth fell. He was defeated and slain in fair fight, at Lumphanan in Aberdeenshire, in 1056, after a reign of seventeen years.

MACCABEES, a Jewish family celebrated for their heroic resistance to the oppression of the Greek kings of Syria in the second century before the Christian era. Their history is given in the apocryphal Books of the Maccabees, and in the 'Antiquities of the Jews' by Josephus. [ANTIOCHUS; ASMONEANS; JEWS; JUDAS MACCABÆUS.]

MACCABEES, THE BOOKS OF THE. Five books have come down to us under this title:—

1. *The First Book of the Maccabees* contains the history of the Jews during forty years, from the accession of Antiochus Epiphanes to the death of Simon Matthes, B.C. 135. The author is unknown. It is generally supposed to be a Greek translation from some Hebrew source, the work, probably, of a Palestinian Jew.

2. *The Second Book of the Maccabees* is abridged from an earlier work in five books, by one Jason of Cyrene, which was compiled from various sources, (2 Macc. ii. 23-32). The author is unknown, but from the style he is supposed to have been a Greek of Alexandria.

3. *The Third Book of the Maccabees* is prior in time to the first and second, and in fact has nothing to do with the history of the Maccabees. It contains the history of the Jews at Alexandria during eight or nine years, from the battle of Raphia in B.C. 217. The author is unknown.

4. *The Fourth Book of the Maccabees* contains an account of the martyrdom of Eleazar and the Seven Brethren (2 Macc. vi. vii.), and of the attempt of Heliodorus to plunder the temple (2 Macc. iii.)

5. *The Fifth Book of the Maccabees* only exists in Arabic and Syriac. It extends from the attempt of Heliodorus to plunder the temple to within a few years of the birth of Christ. The first two books are received by the Church of Rome; the last three

by no Christian church. (Dr. Cotton's *Five Books of the Maccabees*.)

MACCLESFIELD, a municipal and parliamentary borough, in the county of Cheshire, 168 miles N.N.W. from London, and 15 miles S.S.E. from Manchester, is situated on the west side and at the base of a range of high land which is on the borders of Cheshire and Derbyshire, and is a part of the mountain region of the latter county. The Bollin, an affluent of the Mersey, runs through the town. A canal, which unites the Grand Trunk and Peak Forest canals, passes close to Macclesfield, and thus opens a water communication with most parts of England, and a railway extends from Manchester through Stockport to Macclesfield. The town contains four principal streets, diverging from the market-place in various directions; and there are four chief entrances from London, Chester, Manchester, and Buxton. The guild hall is a modern Greek edifice, of graceful design, and the public room is well adapted for concerts and meetings. A subscription library contains about 20,000 volumes. The court-house and gaol are situated in the market-place. The town is lighted with gas, and supplied with water conducted in pipes from the adjoining hills. The various factories are situated on the Bollin. One of the cotton factories cost 30,000*l.*, and some of the silk factories 14,000*l.*; but the value of the latter has been much depressed by the deterioration of the silk-trade. The town contains a dispensary, a savings bank, a free grammar-school, endowed in 1502, and many trusts for charitable purposes.

St. Michael's church was founded by Eleanor, queen of Edward I., in 1278. There are six other churches in the town, besides one in each of the suburbs, Sutton and Hurdfield. There are also various places of worship belonging to different classes of dissenters.

Macclesfield is one of the chief seats of the silk-throwing trade, which progressively advanced from 1808 to 1825, when it attained its greatest prosperity. It has since been much prosperous, but is still large, employing upwards of seventy mills. Every variety of silk article is produced here, from the narrowest riband to the different kinds of sarsonets, plain and figured gros de Naples, satin, silk, vestings, and velvets. It is likewise the chief place for the manufacture of silk handkerchiefs of every description. It has two weekly markets, and five annual fairs.

The municipal borough is divided into six wards, and is governed by twelve aldermen and thirty-six councillors. The population of the borough, which returns two members, in 1861, was 36,101. The parliamentary and municipal limits are co-extensive. The number of voters on the borough register in 1866 was 949.

M'CRIE, THOMAS, was born at Dunse in Berwickshire, November, 1772. He entered at the University of Edinburgh in 1788, and was licensed as a clergyman, in 1795, in that branch of the secession from the Church of Scotland termed Anti-Burghers. He was immediately afterwards chosen pastor of a congregation in Edinburgh, where he continued to reside during his whole life. In 1812 he published 'The Life of John Knox;' and this was followed by 'The Life of Andrew Melville.' Both

of them are works of great research and much merit, though written with strong feelings in favour of the subjects of his biographies. Their author led a blameless, simple life, and died August 5, 1835.

MACDONALD, ETIENNE JACQUES JOSEPH ALEXANDRE, Duke of Tarentum and Marshal of France, was born November 17, 1765, at Sancerre, in the department of Cher, though some authorities make Sedan the place of his birth. He became one of Napoleon's most distinguished generals. His rise in the French army was extremely rapid. He first served on the staff of General Dumouriez during the Revolution. Under Pichegru he distinguished himself by the passage of the Waal, and was made general of division. Subsequently he was made governor of Rome; he commanded at Versailles during the 18th Brumaire, and in 1800, as commander-in-chief of the reserve army of Switzerland, effected his celebrated passage of the Splügen, which was more difficult than that of Napoleon over the Great St. Bernard.

His brilliant exploits under Napoleon belong to history. Napoleon himself presented him with the marshal's baton on the field of Wagram. In April, 1810, he was created Duke of Tarentum. He was with Napoleon in his Russian and German campaigns, adhered to him faithfully in his decline, and endeavoured to procure favourable terms for him from the allies.

On the first restoration of the Bourbons, Macdonald was called to the Chamber of Peers. He steadily refused to join Napoleon on his return from Elba, and on the second restoration of the Bourbons was named chancellor of the Legion of Honour, which office he retained till 1831. He died at Paris, September 24, 1840.

MACDUFF. [BANFFSHIRE.]

MACE. [MYRISTICAL.]

MACEDO'NIA. The boundaries of this country varied at different times. In the days of Strabo it included a considerable part of Illyricum and Thrace; but Macedonia Proper was separated from Thessaly on the south by the Cambunian mountains; from Illyricum on the west by the great mountain chain called Scardus and Bernus, and which under the name of Pindus also separates Thessaly from Epirus; from Mæsia on the north by the mountains called Orbélus and Scomius, which run at right angles to Scardus; and from Thrace on the east by the river Strymon. The Macedonia of Herodotus was still more limited. Macedonia Proper, as defined above, is watered by three large rivers, the Axios (*Vardar*), the Lydias, and the Haliacmon, which flow into the Thermaic Gulf (the modern Gulf of Saloniki). The whole of the district on the sea-coast, and to a considerable distance in the interior, between the Axios and the Haliacmon, is low and marshy. The only other rivers of any importance were the Strymon and the Angites, whose valleys were separated from that of the Axios by a range of mountains which run from Orbélus on the north towards the peninsula of Chalcidice. The Strymon (*Struma*) rises in Mount Scomius, and flows into the Strymonic Gulf (*Gulf of Orphano*). Not far from the sea it forms a lake, called Cercinitis (*Kerkine*) into which the Angites flows from the eastward.

The Macedonians were probably an Illyrian people, though it appears that their princes were an Hellenic

race, and parts of the country were inhabited by Hellenic tribes from an early period. Perdiccas is usually regarded as the founder of the kingdom, the limits of which were confined to the country in the neighbourhood of Edessa, between the Lydias and the Haliacmon. Very little is known of its history till the reign of Amyntas I., who was king at the time of the expulsion of the Pisistratidae from Athens, B.C. 560. Amyntas was succeeded by his son Alexander I., who was obliged to accompany the Persian army into Greece, but was able to render important services to the Grecian cause. The time of Alexander's death is uncertain, but he lived at least to B.C. 463. He was succeeded by Perdiccas II., who took an active part in the Peloponnesian war, and alternately assisted Athens and Sparta. His successor Archelaus (B.C. 413) was the wisest king that had yet sat upon the throne of Macedonia. [ARCHELAUS.]

On the assassination of Archelaus, B.C. 399, confusion prevailed for many years; and it was not till the accession of Amyntas II. (B.C. 393), that order was restored. Amyntas was succeeded by his eldest son Alexander II., who was assassinated at the end of the first year of his reign by Ptolemæus Alorites, who was regent for three years during the minority of Perdiccas; but in consequence of abusing his trust he was cut off by Perdiccas, B.C. 364. Perdiccas, after a reign of five years, fell in battle against the Illyrians, B.C. 359, and was succeeded by his younger brother, the celebrated Philip. [PHILIP.] Philip was succeeded by Alexander the Great. [ALEXANDER.] In the disturbances which followed the death of Alexander the royal family was destroyed, and Cassander obtained at first the power, and eventually the title, of king of Macedon. Cassander was succeeded by his son Philip, B.C. 296, who reigned two years; and on his death, in B.C. 294, his two younger brothers, Antipater and Alexander, having quarrelled respecting the succession, the throne was seized by Demetrius, the son of Antigonus, who reigned seven years. He was driven from his kingdom, B.C. 287, by Pyrrhus, king of Epirus, who was deposed, after a reign of seven months, by Lysimachus, king of Thrace. [LYSIMACHUS.]

On the death of Lysimachus, B.C. 281, the country remained in a state of anarchy for many years, during the invasion of the Gauls from B.C. 280 to B.C. 278, and the contests between the numerous pretenders to the throne. Eventually Antigonus (surnamed Gonatas), the son of Demetrius, was proclaimed king, but was dethroned by Pyrrhus, who again obtained the kingdom on his return from Italy. After the death of Pyrrhus, Antigonus regained possession of the throne, which he retained till his death, B.C. 239. The two following kings, Demetrius II. (B.C. 239-229) and Antigonus II. (B.C. 229-220), were principally occupied in the Grecian wars which followed the formation of the Achæan league. [ANTIGONUS.]

Philip V., who succeeded Amyntas, alarmed at the increasing power of the Romans, entered into an alliance with Hannibal. On the conclusion of the war with Carthage he was unable to cope with the Roman power, and after continuing the contest for a few years, was obliged to sue for peace. Philip was succeeded by Perseus, B.C. 178, who carried on war against the Romans, and was finally conquered,

B.C. 168. Macedonia was divided into four districts, which were considered independent, and governed by their own laws, and of which the capitals were respectively—Amphipolis, Thessalonica, Pella, and Pelagonia. Macedonia was reduced to the form of a Roman province, B.C. 142.

It is very difficult to determine its boundaries at this date. According to the 'Epitomizer' of Strabo (vii.), it was bounded by the Adriatic on the west; on the north by the mountains of Scardus, Orbelus, Rhodope, and Hæmus; on the south by the Via Egnatia; and on the east it extended as far as Cypselæ and the mouth of the Hebrus.

MACER, EMILIUS, a Roman jurist, who lived under the Emperor Alexander Severus, or shortly after his time. He was either a contemporary of Ulpianus, or wrote after Ulpianus, for he cites him several times. There are 275 excerpts from Macer in the 'Digest.'

MACERATA, a province of central Italy, having a fertile soil, an area of 1056 square miles, and in 1863, 239,411 inhabitants. The principal rivers are the Esina, Potaiza, Chienti, and Musone, which rise in the Apennines and flow into the Adriatic.

The chief towns are the following:—*Macerata*, on a hill in a fine country watered by the Chienti, a well-built town, inclosed by walls, with 19,283 inhabitants, several churches and convents with good paintings, a cathedral, theatre, college, and a university with a library containing 20,000 volumes, a handsome town-house, and several fine private palaces, amongst which the palace Compagnoni is the most remarkable. *Macerata* is a bishop's see. It carries on a considerable trade in corn, silk, and cattle. *Loretto*, famous for its sanctuary of the Madonna, called the Santa Casa or holy house, which is said to be the house in which the Virgin Mary lived at Nazareth, and to have been miraculously carried, first to a hill near Fiume in Dalmatia, and finally, in 1294, to its present site, about 15 miles S.E. of Ancona, near the Adriatic coast. The ground on which the house was deposited belonged to a woman called Lauretta, whence the name of Loretto. The town which has grown up around the sanctuary is well built, and in 1862 contained 8000 inhabitants. The celebrated Holy House stands within a magnificent church. It is a small brick house, with one door and one window, originally of rude material and construction, but now, from the devotion of pilgrims for many generations, a marvel of art and costliness. It is entirely cased with white marble exquisitely sculptured. *Recanati*, near the Adriatic, with 3000 inhabitants, is now a small fishing town, but it has a cathedral, a town-hall rich in works of art, a communal and other palaces, and an aqueduct by which water is conveyed to Loretto. Near it are the ruins of *Potentia*. It was an important military post in the middle ages. *Tolentino*, farther inland, near the foot of the Apennines, has a cathedral, and manufactures of dressed skins. Here, in February, 1797, the pope ceded by treaty the Romagna to the French republic; and in May, 1815, Murat retired with his troops before the Austrians. *Camerino*, the ancient Camerinum, an old town among the Apennines, and a bishop's see, with several churches and convents, and some silk factories. *Fabriano*, farther north, a bishop's see, with a cathedral, manufactories of paper

and parchment, and a considerable trade in wool. *San Severino* is 15 miles W.S.W. of Macerata, on the Potaiza, and has 4334 inhabitants. It is a bishop's see, has two cathedrals, and several churches, with many interesting paintings. *Matelica* is 6 miles farther in the same direction, on the eastern side of the Apennines, with a population of 7355, who carry on some manufactures of coarse woollen cloths. It is inclosed by walls, and has several churches and convents.

MACERATION is the steeping of substances in cold liquids, either merely to soften the parts of the substance operated on, or to dissolve the aromatic parts of a substance when *digestion* would not merely dissolve, but dissipate them.

MACERS, in Scotch law, are officers attached to the Courts of Session, Justiciary, Teinds, and Exchequer. Their duties are to preserve silence in court, to call the rolls of court, and to execute such warrants for the apprehension of delinquents as are addressed to them. (*Bell's Law Dict.*, art. *Macer*.)

MACGILLIVRAY, WILLIAM, LL.D., Professor of Civil and Natural History in Marischal College, Aberdeen, was born in the Isle of Harris. Having in early life taken up his residence at Edinburgh, and devoted himself to the pursuit of natural history, he became assistant to Professor Jameson in the Natural History and Geological Museum of the Edinburgh University. He afterwards received the appointment of Curator of the College of Surgeons in Edinburgh. He pursued the study of natural history in all its branches with great ardour. After having been appointed to the professorship of natural history in Marischal College, Aberdeen, he produced several valuable works, which have largely contributed to the interests of science. In 1839 he brought out a 'Manual of Geology, with a Glossary and Index,' and afterwards a 'History of British Birds,' a 'History of British Quadrupeds,' a 'History of the Molluscous Animals of the Counties of Aberdeen, Kincardine, and Banff,' 'Conchologist's Text-book,' the last of which has been very successful. He died in 1852.

MACGILLYCUDDY REEKS. [*KERRY.*]

MACHAIRODUS, a genus of extinct animals established by Professor Kaup upon those canine teeth with serrated or denticulated edges which have been attributed to bears (*Ursus cultridens*, &c.) by Cuvier and others, and to great cats (*Felis*) by Bravard.

Professor Owen has no doubt that the teeth belonged to a mammiferous animal; and the proof is afforded by the specimen examined, which shows that the tooth was originally locked in a socket, and not anchored to the substance of the jaw, and that the fang is contracted and solidified by the progressive diminution of a temporary formative pulp, and does not terminate in an open conical cavity, like the teeth of all known Saurians, which are lodged in sockets. Careful comparison will show that the canine teeth of *Machairodus* are very far from those of the bears, and sufficiently removed from those of the tiger, though those of the latter present serrated edges. On looking at the catalogue of the extinct species found at Epplesheim, we do not find any large fossil ruminant noticed, though we find large cats, some as large as a lion, and another carnivorous animal (*Agnotherium*), allied to the dog and also as large

as a lion; and we are not without existing ruminants with very long canine teeth in the upper jaw with serrations on their edges, though not so broad in proportion as those of *Machairodus*.

MACHECOUL. [*LOIRE-INFÉRIEURE.*]

MACHIAVELLI, NICCOLO' DI BERNARDO DEL, was born at Florence in 1469, of an old though not wealthy family of that republic. When twenty-nine years of age, he was made secretary of the 'Ten,' a board which had the management of foreign affairs. His abilities and penetration being soon perceived by his superiors, he was successively employed on many and some very important missions. In the year 1500 he was sent as a commissioner to the Florentine camp before Pisa, and subsequently to Paris to conciliate the king towards the Florentines. On both occasions his labours were crowned with success.

In 1502 he was despatched as ambassador to Duke of Valentino, the formidable Cæsar Borgia, who was then at Imola in Romagna, to make professions of friendship on the part of the Florentines. His account of this mission is extremely curious. Borgia's object was to obtain the command of the Florentine forces; that of Machiavelli to refuse it without offending the tyrant. In August, 1503, Alexander VI. died, and his successor, Pius III., died a few days after. A new conclave being assembled in October, the Florentines sent Machiavelli to Rome, where he was present at the election of Julius II., and soon after witnessed the fall of Cæsar Borgia. After visiting France, Rome, and some other places, on various missions, Machiavelli was sent in 1507 to the Emperor Maximilian in Germany. On his return he wrote several reports on the affairs of Germany: 'Rapporto sulle Cose di Lamagna;' 'Discorso sopra le Cose dell' Alemagna;' 'Ritratti di Lamagna.'

In February, 1509, he was sent to the camp before Pisa, which was besieged by the Florentines, and in July, 1510, to France a third time. The object of this mission was to encourage the French court to maintain the alliance with the pope and the emperor against the Venetians (the league of Cambrai), and to induce Louis to prevent the Swiss from enlisting in the service of the pope. Machiavelli returned to Florence in September, 1510, having consolidated the alliance of Florence with France.

When in 1512 the Medici possessed themselves of Florence, Machiavelli, with others of the popular government, was banished, and subsequently imprisoned and put to the torture on suspicion of being implicated in a conspiracy against the Medici. He persisted in declaring himself innocent, and was released by the intervention of Leo X. He then withdrew from public life, and wrote his discourses upon Livy, his books on the art of war, and his 'Principe.' In this work he treats of what he terms mixed principalities, as distinct from republics and hereditary monarchies. The 'Principe' was first published, after Machiavelli's death, at Rome in 1532. The 'Legazioni,' or letters of the political missions of Machiavelli, which are the key to his 'Principe,' were not made public till the middle of the last century.

The chief works of Machiavelli, not mentioned above, are:—'Storie Fiorentine,' which he presented to Clement VII. in 1525, and which come down to the death of Lorenzo the Magnificent, in 1492; and

he has left fragments which bring down the history of Florence to 1499; 'La Mandragora,' and 'La Clizia,' two comedies; 'Sette Libri dell' Arte della Guerra;' 'Discorso si la Lingua di Dante, Boccaccio, e Petrarca, debba chiamarsi Italiana, Toscana, o Fiorentina;' besides minor productions and a multitude of letters. The best editions of his works collectively are those of Florence, 1783, 6 vols. 4to; 1796, 8 vols. 8vo; and 1818, 10 vols. 8vo.

MACHICOLATION, a term applied to those openings in the parapet of a fortified building through which ignited combustibles, melted lead, stones, &c., were poured and hurled down upon the besiegers. The apertures were formed in the soffit or under surface of the projecting parapet, which was supported upon corbel stones, the perforations themselves being in the soffit, between those stones. By this contrivance the besieged were enabled to harass their assailants, while they themselves were protected by the parapet and its battlements. Machicolations were frequently confined to particular situations, such as over an entrance-gateway and the towers flanking it, or other parts most likely to be assaulted.

MACHINE, an object by the intervention of which a motive power is made to act upon any body, and overcome the force by which the latter resists the effort to change its state of rest or motion. The advantage which any machine affords for overcoming resistance consists in the reaction by which it supports a certain portion of the weight producing that resistance, so that the motive power has only to counteract the remainder. This may be immediately observed in those simple machines called the mechanical powers. For example, in the lever, the wheel and axle, and the pulley, any convenient portion of the resistance may be made to rest on the point of support, or the point of suspension. Again, in the inclined plane, the wedge, and the screw, the motive power, the resistance, and the reaction of the support being, in the case of equilibrium, represented by the three sides of a triangle, the ratio of the first to either of the others may be varied at pleasure by the construction of the machine.

The powers employed to give motion through machinery to any object, are produced by the muscular strength of men or animals; the actions of weights, springs, wind, water, heat, and electricity; and these powers may generally be considered as pressures exerted during certain portions of time. Even that power which is produced by a sudden impulse, as when a rammer descending by its weight falls on the head of a pile, is only a pressure existing during an indefinitely short interval of time. The point in any machine to which the moving power is applied is called the impelled or driving point, and that against which the resistance acts is called the working point.

In estimating the power of a machine, it is usual to make the measure of the power depend on the condition that the impelled and working points shall be in a state of uniform motion. For then, agreeably to the law of the conservation of energy, the velocities of those extreme points are inversely proportional to the forces which would be in equilibrio at the same points; the same principle in other words being that in every machine, simple or complex, the pressure at the impelled point, multiplied by the velocity of that

point, is equal to the product of the resistance at the working point by the velocity of the same point; or work done is equal to energy excited. When there are several working points, the whole work done is the sum of the quantities of work done at those points; and the energy exerted is equal to that sum.

The whole work done by a machine is distinguished into useful work and wasteful work, according as it is done in overcoming useful and wasteful resistance. For example, in a pumping engine, the work done in raising the water is useful, and that done in overcoming friction wasteful. The ratio of the useful work to the whole work is called the *efficiency* of the machine, and is always a fraction less than unity.

MACHINE, CALCULATING. [**CALCULATING MACHINE.**]

MACHINES OF WAR. Among the ancients there was a great variety of destructive implements in use, which are frequently mentioned in the history of ancient warfare. Thus the Greeks had the Battering Ram; the Chelone, or tortoise; the Scaling ladders (Climaces); the Helepolis, the Chroma, or Agger, which was raised higher than the wall; the Catapulta, from which they threw arrows; Purgi, towers of wood; and Lithoboli, from which stones were thrown with great velocity and force. Among the Romans, the principal machines of war were:—the Aries, or Ram; the Testudo, or tortoise; the Ballista; the Catapulta; the Scorpion; the Bel-fragium; the Pluteus, &c. The Roman machines were adopted under various names in the middle age. Besides the above, Grose enumerates the Mangona, the Trebuchet, the Petiary, the Mafafunda, the Warwolf, &c., for throwing stones; the Bricolle, the Espringall, &c., for throwing darts; and the Cat for sieges.

MACINTOSH CLOTH (so called from the inventor) is a singular but very useful manufacture, consisting of two layers of fine cotton, cemented with a solution of caoutchouc in coal naphtha, or liquid india-rubber, and so completely conjoined as to appear one material. The cotton pieces, thus coated with the liquid, are passed between two smooth wooden rollers, and so thoroughly pressed as to be made to unite permanently and durably. Cloth thus prepared, when perfectly dried, may be cut and made into garments which will bear the roughest wear, and be impervious to the most soaking rains. For travelling overcoats they are of great service.

MACKENZIE, the name of a large river in British North America, rises in the Great Slave Lake, and running in a north-westerly direction enters the Atlantic by several mouths, about lat. 68°-50' N. Forts Simpson, Norman, and Good Hope are on its banks. The Mackenzie is estimated to be 870 miles long, though from the source of the Slave River, the principal feeder of the Slave Lake, to the ocean is over 1770 miles. An extensive deposit of lignite accompanies its course and its estuary westward. It takes its name from its discoverer, Alexander Mackenzie, by whom it was first navigated in 1789.

MACKENZIE, SIR ALEXANDER, emigrated from Scotland to Canada when a young man. He rendered important services to geographical knowledge by his intrepid expeditions from Fort Chipewyan down the Mackenzie River to the Northern Ocean, in

lat. 68° 50, in 1789; and from Montreal through the continent to the Frozen and Pacific Oceans, in 1792. Of this last expedition he has left a full account, published in London, 1801.

MACKENZIE, SIR GEORGE, of Rosehaugh, was born at Dundee in 1636. He was by profession a lawyer, and held for many years the important situation of justice-depute. He represented Ross in the Scottish Parliament. He is known chiefly by his 'Institutions of the Laws of Scotland,' 1684, a concise and excellent compendium of the law; and his 'Moral Essay upon Solitude.' He wrote, however, many other works, and was among the first Scotchmen who wrote the English language in a style approaching to purity. He died May 2, 1692.

MACKENZIE, HENRY, was born at Edinburgh in August, 1745. He was the son of Dr. Joshua Mackenzie, a physician. Educated at the high school and university of his native city, he afterwards became one of the attorneys in the Scottish Court of Exchequer. While in London, in 1765, studying the English practice in Exchequer, he had begun to write his earliest and best novel, 'The Man of Feeling,' which was published anonymously in 1771. In 1783 he published his second novel, 'The Man of the World;' and next came 'Julia de Rouigné,' his last considerable work of this class. Meantime he had edited two well-known periodicals: 'The Mirror,' which continued to appear weekly for seventeen months from January, 1779; and 'The Lounger,' which, begun in February, 1785, came to a close about two years afterwards. Besides minor productions he wrote several plays, of which the principal are, 'The White Hypocrite,' 'The Spanish Father,' and 'The Prince of Tunis.' He was likewise a political writer in the Tory interest. In 1808 he edited a complete collection of his literary works, in eight octavo volumes; and this was almost his last contribution to literature. He died in Edinburgh, January 14, 1831.

MACKEREL. [SCOMBRIDÆ.]

MACKINTOSH, SIR JAMES, the historian, was born at Aldourie, on the banks of Loch Ness, October 24, 1765. He received his education at the universities of Aberdeen and Edinburgh, came to London, and was called to the bar in 1795. In 1804 he went to India as recorder of Bombay. He returned to England in 1812; in 1818 he was appointed to the professorship of law and general politics in the college instituted for the education of the civil servants of the East India Company at Haileybury. In 1830, when the Whigs came into office, Sir James was appointed a commissioner for the affairs of India. He died May 30, 1832.

Sir James' principal works are his 'Vindiciæ Gallicæ,' his 'History of England' (which he left unfinished at his death); his 'Dissertation' prefixed to the 'Encyclopædia Britannica;' and his 'Life of Sir Thomas More.'

MACKLIN, CHARLES, actor and dramatist, according to the account of a female relative, 'was two months old at the battle of the Boyne' (July 1, 1690). He began life as a saddler's apprentice, but in his twenty-first year joined a strolling company as harlequin, and pursued the vocation of an actor thenceforward with various fortune till 1789. He died in London, July 11, 1797. He was a clever

actor, and celebrated for his performance of Shylock. He also wrote several dramatic pieces, of which 'Love à la Mode,' a farce, and the 'Man of the World,' a comedy, are occasionally performed.

MACKNIGHT, JAMES, D.D., born 1721, died 1800, was a clergyman of the Church of Scotland, and of considerable eminence among the theological writers of the last century. He wrote 'A Harmony of the Gospels, with copious illustrations, being in fact a life of our Saviour, embracing everything which the Evangelists have related concerning him;' and 'A new Translation of the Epistles.' Both these works were favourably received, and are by many persons highly esteemed.

MACLAURIN, COLIN, was born at Kilmoran, in Argyleshire, in February, 1698. The care of his education devolved upon an uncle, who sent him to the University of Glasgow at the age of eleven. It is said that in the following year, meeting accidentally with a copy of Euclid, he made himself master of the first six books in a few days, a story utterly incredible upon the mere statement. It is said also, and with much more likelihood, that at the age of sixteen he had invented many of the propositions afterwards published in his 'Geometria Organica.' However this may be, he took the degree of Master of Arts with distinction in the fifteenth year of his age (1713), and afterwards lived in studious retirement till the autumn of 1717, when, after a severe competition and ten days' examination, he obtained the professorship of mathematics at the Marischal College, Aberdeen. In 1719 and in 1721 he visited London, and formed the acquaintance of many eminent men, particularly of Newton.

In 1725 he was appointed to assist James Gregory, whose strength was declining, in the duties of his chair at Edinburgh. The want of funds to pay an assistant placed difficulties in the way of this arrangement, which were removed, but how is not clearly stated. We mention them here to record, in honour of Maclaurin, that Newton, on hearing of the obstacles, offered to pay twenty pounds a year, till Gregory's death, towards the assistant's salary, if Maclaurin were to be appointed. At Edinburgh he remained almost all the remainder of his life. When the rebellion broke out in 1745, he exerted himself vigorously for the existing government, and the hasty works which were thrown up for the defence of Edinburgh were planned and superintended by him: fatigue and exposure laid the foundation of a mortal disorder. When the Pretender entered Edinburgh, Maclaurin withdrew, to avoid making the submission which was demanded: but he had previously managed to introduce a good telescope into the castle, and to contrive a method of supplying the garrison with provisions. He accepted the invitation of Dr. Herring, archbishop of York, with whom he remained till it was safe to return to Edinburgh. Shortly after his return, he died of dropsy, June 14, 1746, aged forty-eight years.

The writings of Maclaurin are not numerous, but they have exercised considerable influence upon the mathematical studies of this country; more however, we think, in what has been taken from them, or on their model, by others, than in the extensiveness of their own circulation.

MACLE (*Chiastolite*) is a right rhombic crystal,

composed of two substances; one of a yellowish white, sometimes translucent, and of a glassy fracture; the other bluish black, opaque and dull. It is, in fact, a silicate of alumina, and contains a small portion of oxide of iron and magnesia.

MACLUREITE (*Condrodite*, *Brucite*) occurs imbedded in rounded masses, the larger of which present occasional crystalline appearances of rhombic prisms with dehdral terminations. It consists principally of silica and magnesia.

MACON, the *Matisco* of Julius Cæsar, the capital of the French department of Saône-et-Loire, is situated on the right bank of the Saône, in 46° 18' N. lat., 4° 50' E. long., 40 miles N. from Lyons, on the Paris-Lyons Railroad, and has 18,006 inhabitants. The town stands on the slope and at the foot of a hill above the Saône, along the bank of which is a noble quay, from which the distant Alps may be seen. The chief public buildings are—the cathedral, old episcopal palace, Hotel de Ville; national college, and normal school; the town-hall, which contains a theatre and public library; the general hospital, on the parade; the church of St. Vincent; and the prison. Among the Roman antiquities are a triumphal arch and the ruins of a temple of Janus. The inhabitants carry on a considerable trade in the wines of the district, corn, cattle, &c. There are manufactures of blankets, leather, earthenware, watches, and jewellery. It was the birthplace of Lamartine.

MACON. [GEORGIA.]

MACPHERSON, JAMES, was born in 1738 at the village of Ruthven, in Inverness-shire. He studied at King's College, Aberdeen, and on leaving college he was appointed schoolmaster of his native village; and it was while holding this situation that he gave to the world what appears to have been his first publication, a poem entitled 'The Highlander,' in 1758. He afterwards became known for his enthusiastic love of the ancient poetry of Scotland, which he translated from the Gaelic, and published at different times between 1759 and 1763. He attributed these poems to Ossian, which occasioned a lively controversy among the learned of the day as to their genuineness. From a recent investigation, conducted by competent authorities, it has been conclusively established that the Ossianic poems are not authentic, though undoubtedly embodying many Gaelic ballads and traditions. In 1771 he published a disquisition on the antiquities of the Scottish Celtic race, under the title of 'An Introduction to the History of Great Britain and Ireland;' in 1773 a prose translation of the 'Iliad' of Homer; in 1775 a 'History of Great Britain from the Restoration to the Accession of the House of Hanover,' in 2 vols. 4to, together with two volumes of 'Original Papers,' which last work he sold to the booksellers for 3000*l*. At last his appointment to the lucrative office of agent to the nabob of Arcot turned his attention and pen to Indian affairs; and he was brought into Parliament in 1780, as member for Camelford, for which he sat till 1790. He died February 17, 1796.

MACQUARIE, a river of New South Wales called by the natives *Wambool*, is formed by the junction of the Fish and Campbell rivers, in the counties of Bathurst and Westmoreland, and flows N.W. to lat., 36° 45' S., long. 145° 20' E. where it loses itself in the Macquarie marshes, from whence issue tribu-

taries of the river Darling. In some places it is deep, broad, and navigable, in others rapid, and obstructed by falls; its total course is about 230 miles.

MACRA'SPIS (*MacLeay*), a genus of Coleopterous insects of the section *Lamellicornes*, and, according to Latreille's classification, belonging to the third division of that group, the *Xylophili*. The genera *Macraspis* and *Chasmodia* constitute two closely allied groups of the family *Rutelidæ*, the species of which inhabit the warmer parts of South America, and are remarkable for the large size of their scutellum.

The insects of these two genera fly by day about trees, emitting a humming noise, and feed upon flowers. Collections formed in Brazil usually contain many of these insects.

Dejean, in his 'Catalogue des Coléoptères,' enumerates twenty-six species of *Macraspis* and five of *Chasmodia*.

MACRAUCHENIA, Professor Owen's name for a large extinct mammiferous animal, referable to the order *Pachydermata*, but with affinities to the *Ruminantia*, and especially to the *Camelidæ*.

The remains on which the professor founded this genus included two cervical vertebræ, seven lumbar vertebræ, all more or less fractured; a portion of the sacrum and ossa innominata; fragments of the left scapula, of the right radius and ulna, and right fore-foot; the right femur nearly entire, the proximal and distal extremities of the right tibia and fibula; and a metatarsal bone of the right hind-foot. These portions of the skeleton were discovered by Mr. Darwin in an irregular bed of sandy soil, overlying a horizontal accumulation of gravel on the south side of Port St. Julian, on the east coast of Patagonia, and belonged to the same individual.

MACROBIUS, AMBROSIUS AURELIUS THEODOSIUS, probably lived about the middle of the fifth century of the Christian era. The place of his birth is uncertain; but he says, in his preface to the 'Saturnalia,' that the Latin language was not his mother-tongue.

Three works of Macrobius have come down to us: a commentary on the 'Somnium Scipionis' in the sixth book of Cicero's 'Republic;' 'Dialogues' which were supposed to have taken place during the Saturnalia at the house of Vettius; and a 'Treatise on the Latin and Greek Verb,' which, however, is imperfect. The 'Saturnalia' is the most important and interesting. Although written in indifferent Latin, and full of trifling absurdities, it contains much valuable information. It is divided into seven books.

MACRODACTYLES, Cuvier's name for a family of Wading Birds (*Echassiers*) [GRALLATOIRES], which have very long feet, formed for running over marshy or water plants, or even for swimming, especially in those numerous species which have the feet fringed or bordered. There is not, however, any membrane between the bases of their toes, not even between those of the external ones.

The following genera are arranged by Cuvier under this family, which terminates his order *Echassiers*:—*Parra*, *Palamedea* (including *Charina*), *Megapodius*, *Rallus*, *Fulica*, (including *Gallinula*, and *Porphyrio*), *Chionis*, Forst. (*Vaginalis*, Lath.), *Glaucola*, Gm., *Phenicopterus*. Cuvier's sixth order, *Palmipedes*, immediately succeeds this family, which is somewhat heterogeneous, and composed of birds

whose habits are not similar. *Phanicopterus* cannot be said to be without any membrane 'between the bases of the toes,' &c., for its anterior toes are united to the nails by a lunated membrane. [FLAMINGO.]

MACROOM. [CORK.]

MACROPO'DIANS, a tribe of brachyurous decapod Crustaceans, being the first of the family of *Oxyrhynchi* (Milne-Edwards), and nearly corresponding with the genus *Macropus* of Latreille, remarkable for the enormous length of their feet, which has obtained for them the name of *Sea-spiders*.

Habits, Food, &c.—The localities of the Macro-podians are considerable depths in the sea, where they lie hid among the sea-weeds; they are also found on oyster banks. They walk slowly and unsteadily. The weakness of their claws must render them not formidable to other marine animals, and the probability is that they live principally on *Annelids*, *Planarie*, and small molluscs. (Milne-Edwards.) The genera are numerous.

MACRO'PUS, the scientific name for the Kangaroos. [MARSUPIALIA.]

MACROURA, or MACRU'RA, the scientific name for that section of Crustaceans which have the abdomen, usually called the tail, long, in contradistinction from that section (*Brachyura*) which have the tail short. The common lobster is an example of a macrurous crustacean, and the common crab of a brachyurous crustacean. [CRUSTACEA.]

MACTRA, a genus of conchiferous mollusca, under which above sixty species are ranged, forming the family *Mactridae*, or kneading trough shells, of which Mactra is the type. There are between thirty and forty fossil species, belonging chiefly to the *Lias*. The *Mactridae* are found in all seas, though they occur in greatest abundance in those of the tropics, to a depth of above thirty fathoms. The shell is nearly equilateral. The animal has its mantle partially open, its margins fringed, with foot large, linguiform, and heeled. The *Mactridae* are favourite food of the star fishes.

MACULÆ (Lat. 'spots'), dark spots, supposed to be openings in the atmosphere or vapour, but apparently looking like blemishes on the surface of the sun and moon, and on some of the planets. The solar spots vary greatly in size and duration. They were first observed by Galileo in Italy, and Harriot in England.

MC'ULLAGH, JAMES, F.R.S., Professor of Natural Philosophy in the University of Dublin, was born at Lough-lindhuussey, co. Tyrone, in Ireland, in 1809. He was educated at the school of the Rev. J. Graham, at Lifford; and in 1824 entered Trinity College, Dublin, as a pensioner. Throughout his undergraduate course he gained every honour both in science and classics. In 1835 he was appointed Professor of Mathematics; and in 1843 was selected to fill the chair of Natural Philosophy. In 1830 he read his first paper on refracted light before the Irish Academy; and in 1838 received the Conyngham gold medal for a valuable paper 'On the Laws of Crystalline Reflexion and Refraction.' In 1842 he received the Copley medal of the Royal Society for his investigations on the theory of Light; and in 1843 he was elected a Fellow of that learned body. He died in 1848.

MADAGASCAR (called by the natives Made-

casse), a large island in the Indian Sea, about 240 miles (across the Mozambique Channel) from the coast of Mozambique on the eastern shores of Africa, extends from 12° S. lat. to 25° 45' S. lat., and between 43° and 51° E. long. Its length is 1030 miles; its greatest breadth 360 miles. The population is variously estimated at from 1,600,000 to 4,000,000. A mountain range traverses the island in its whole length, and some of the summits rise to an elevation of 10,000 or 12,000 feet. Its offsets cover the greater part of the interior, and in some places approach to the very shores of the sea. In the interior the country in many places contains extensive plains, which are excellent pasture ground, and frequently possess a soil adapted to all kinds of tropical plants.

Bambatooka Bay, on the western coast, is the estuary of several rivers. It is 17 miles in length, and three and a half wide at the entrance; but inside it is nearly eight miles wide. Bambatooka itself is an inconsiderable village, but Majunga, on the north side of the bay, is a large town and the harbour of Thanaan-arive, the capital of the Ovahs, the most powerful, industrious, and civilized nation of the island. Thanaan-arive is situated in 18° 56' S. lat., and about 47° E. long., at an elevation of about 4000 feet above the sea-level. It contains some well-built houses, and a few in the European fashion have been erected in modern times.

The climate of Madagascar, everywhere unfavourable to Europeans, is not so hot as might be expected from its geographical position. The elevated range in the interior, and the wind constantly blowing from the sea, render the heat supportable. Madagascar contains a very large proportion of fertile soil, and will produce nearly every kind of grain. Rice is the principal object of agriculture; but grain and fruits are cultivated in abundance, as are likewise sugar, pepper, tobacco, and coffee. Cattle, sheep, fowls, ducks, and geese are kept. Wild swine are numerous. Among the minerals are iron, tin, silver, copper, plumbago, and potter's clay.

The inhabitants seem to belong to different races, which have mixed together, and speak only one language, which contains a great number of Malay words. The Ovahs and the inhabitants of the coast differ in stature, hair, and features; but both nations have made much progress in arts and agriculture. Their language is written in the Arabic character. Their religion is idolatry, not founded on any sacred writings; and missionary enterprise had made some progress among them, when it was checked by violent means in 1835.

Madagascar is divided into twenty-eight states, governed by chiefs; but in the present century most of them were subjected to the sway of the Ovahs, by King Radama, who died in 1828. This extraordinary man, who in energy of character resembled Peter the Great, introduced into his country the arts and civilization of Europe. He established a communication with the English in the island of Mauritius. He received and protected the missionaries, and promoted the establishment of schools, the number of which at the time of his death had increased to more than 100, in which nearly 5000 children were instructed. Several young people were sent to the Mauritius, and even to England, to

receive instruction. European mechanics were well received and employed by Radáma. He introduced into his army the discipline and arms of the English. He was succeeded by his queen, who governed on entirely opposite principles. She died in 1861, and was succeeded by her son Radáma II., who was strangled in 1863, and the government, now constitutional, devolved on his queen. Since 1862 European consuls have been established at Antanarivo, the capital, nearly in the centre of the island, and the distinguished missionary, Mr. Ellis, has a Christian congregation of about 1000 there, besides six others of nearly equal size.

The French alone have tried to establish colonies on this island. The first attempt was made in 1665, and several others were made afterwards. These settlements never prospered, partly on account of the unhealthiness of the low western coast, where they were formed, and partly on account of the warlike character of the inhabitants. The French have again made some attempts in two or three places, which, however, have had but little success. The French and English trade a little with Madagascar; and some districts keep up a commercial intercourse with the southern coasts of Arabia.

MADDALONI. [LAVORO, TERRA DI.]

MADDER. [RUBIA.]

MADEIRA, an island situated in the Atlantic Ocean, between $32^{\circ} 30'$ and $32^{\circ} 53'$ N. lat., and $16^{\circ} 40'$ and $17^{\circ} 20'$ W. long., and about 400 miles from the north-western coast of Africa. It is 31 miles long, and its breadth 12 miles. The area is 360 square miles.

This island is one mass of basalt, rising with a rather steep ascent from the south and from the north towards the interior, where Pico Ruivo, the highest summit, attains to 6100 feet above the sea-level. Both declivities of the mountain pass are furrowed by deep and generally narrow valleys and depressions, traversed by streams of clear water. These valleys contain the gardens and vineyards. The climate of Madeira is very mild; and many persons in England who are suffering from or in danger of consumption withdraw to it for the purpose of diminishing their sufferings and prolonging their life.

In the lowest region of the island, to about 750 feet above the sea-level, many tropical plants are cultivated. Above this region, to a height of from 750 to 2500 or 2800 feet, the fruits and grain of Europe, especially wheat and maize, are raised; and in this region are also the extensive vineyards, which till recently furnished the most important article of exportation. Then follows a tract covered with high trees, which rises to 3200 feet and higher, where many plants and trees are found which do not occur in Europe; and above this level is a region of grass, fern, and heath. Few horses are kept, and most of them are imported. Cattle are more numerous, and of a large size. Asses are the most common domestic animals, and best adapted to the roads of the country as beasts of burden. Hogs are rather numerous, as well as fowls. In the interior there are many wild swine and rabbits. Birds are not numerous, and fish is rare, on account of the great depth of the sea which surrounds the island. Salted cod constitutes one of the principal articles of import.

VOL. VIII.

Funchal, the capital, and the only town of the island, is on the southern coast. The town consists of a pretty wide street along the sea-shore, where there are several good buildings, and numerous small lanes, which extend to a considerable distance up the slope of the hill. The number of inhabitants is 29,775. The town is defended by four forts, and has eight churches and several convents. In the midst of the town is an open square, planted with trees.

The number of inhabitants in the Madeiras in 1863 was 104,420, of whom 300 were English. The population of the island are descendants of the Portuguese, but with a considerable mixture of African blood. The number of negro slaves is still considerable, and was formerly much greater. The inhabitants are a very industrious and enterprising people.

The commerce of Madeira is considerable. The exports consist chiefly of Madeira and Malvasia de Madera wines. Minor articles of export are, fruits, dragon's-blood, honey, wax, orchil, and tobacco, besides provisions for the vessels bound to more remote places. The imports consist of manufactured goods, corn, fish (herrings and cod), oil, salt-beef, salt, and some tropical productions. The exports from Madeira to England have decreased of late years. In 1860 they were valued at 45,431*l.*, and in 1864 at only 17,261*l.* This is in consequence of the falling off in the supply of wine, which is the principal article sent to this country. The imports from England, consisting chiefly of coals and cotton goods, were valued at 71,500*l.* in 1864.

Madeira is said to have been visited by Robert Machin, an Englishman, during the reign of Edward III. It was rediscovered in 1419 or 1420 by Gonzalves Zarco. It derived its name from the timber (*madéra*) with which it was covered. Soon afterwards it was settled by the Portuguese, and the culture of sugar and wine was introduced. Sugar was grown to a considerable extent before the islands in the West Indies were settled; but upon that event the culture decreased, and was replaced by that of wine, which now seems to be giving way to coffee.

About 40 miles north-east of Madeira lies the small island of *Porto Santo*. It is a basalt rock, which does not exceed 500 feet in height. To the south-east are three small basalt rocks, lying in a row from north to south. They are called *Ilhas Desertas*, and are only inhabited by sea-fowl, but they are visited from Madeira for the purpose of collecting the orchil, with which the greatest part of their surface is covered.

MADIA, the name of a genus of dicotyledonous plants belonging to the natural order *Compositæ*. Of the two known species *M. sativa* is most prized. It is a native of Chili, where it is cultivated for the sake of the oil which it yields. It is either put under a press, or boiled under a low gentle heat, when the oil is to be taken from it. The oil is used for lubricating fine machinery.

MADISON, JAMES, was born March 16, 1751, at King George, near Port Royal, on the Rappahannock River in Virginia. He was educated at the college of Princeton in New Jersey, where, in 1772, he took the degree of B.A. In the spring of 1776 his political career commenced by his being chosen a member of the Virginia convention, which formed the first

A A

constitution of Virginia. He was appointed a member of Congress in March, 1780. He was one of the three commissioners from Virginia who assembled at Annapolis, where he met Alexander Hamilton, with whom he was afterwards so closely united in forming the new constitution, and from whom he was so widely separated in carrying it into execution. His services to the United States cannot be too highly estimated. After the American constitution was formed, he was its zealous expounder to the people. He carried it triumphantly through the legislature of Virginia in spite of a strenuous opposition. He was chosen a member of the first Congress in 1789, and continued a member until 1797. He took an active part in the affairs of his country; and though he often appeared politically in opposition to General Washington, so great was the esteem of the latter for Madison that he intrusted him with the composition of his farewell address on his retirement from public life. In the struggle which succeeded the retirement of the general, Madison took an honourable and influential part, and when Mr. Jefferson was elected president, he was appointed his secretary of state. He succeeded Mr. Jefferson as president in 1809. Under his administration war was declared against Great Britain, to which he was urged by Mr. Clay and some ardent spirits whose patience was exhausted.

After serving two terms, Mr. Madison retired to private life, in March, 1817. In 1829, when the constitution of Virginia was submitted to revision, he consented to serve as a member of the convention. He also acted as a visitor of the University of Virginia, and succeeded Mr. Jefferson as its rector. Although Mr. Madison lived to the age of eighty-five, he had a very delicate constitution, and never enjoyed good health. He died January 28, 1836.

MADNESS. [INSANITY; LUNACY.]

MADONNA (*Ital.* 'my lady'), a word much used in the Roman Catholic Church in reference to the Virgin Mary. The Madonna and Child have been the subject of innumerable paintings by the great masters; but the grandest success has undoubtedly been achieved by Raphael, who has represented the Madonna now as the loving mother, then as the ideal of female beauty, and last of all as the Queen of Heaven. In Mrs. Jameson's 'Legends of the Madonna' (London, 1852), a complete history of the subject will be found, accompanied with numerous explanatory engravings. It would appear that no attempt was made to represent the features of the mother of Christ till the fifth century, when she was declared to be the 'Mother of God.' At first her face was made full, oval, and of a mild expression, and the lineaments of her countenance copied from the older pictures of Christ, according to the tradition which declared that he resembled his mother. As Mariolatry developed in the Roman Catholic Church, the representations of the Virgin became more and more sublime, until they may be said to have culminated in Raphael's 'Queen of Heaven' before referred to. She was, however, never represented without a child until comparatively recent times.

MADOX, THOMAS. Of the personal history of Madox little is known. His first work appeared in 1702, entitled 'Formulare Anglicanum; or a Collection of ancient Charters and Instruments of divers

kinds, taken from the originals, from the Norman Conquest to Henry VIII.' In 1711 he published his great work, entitled, 'The History and Antiquities of the Exchequer of the Kings of England, in two periods; from the Norman Conquest to the end of the reign of King John; and from the end of the reign of King John to the end of the reign of Edward II., taken from Records.' In 1726 Mr. Madox published his 'Firma Burgi, or an Historical Essay concerning the cities, towns, and boroughs of England, taken from Records.' A posthumous work from the pen of Mr. Madox, entitled 'Baronia Anglica,' a history of the land-honors and baronies, and tenure in capite, verified by records, in which he corrects the errors into which Lord Coke and others have fallen in the use of these terms, appeared in 1736. The date of his death is not known. Mr. Madox held the office of historiographer royal.

MADRAS, one of the three great presidencies into which British India is divided for administrative purposes, occupies an extensive portion of the south of the Indian peninsula. Area, 355,846 square miles; population, 43,528,265. It contains the following six divisions:—

1. The **NORTHERN**, comprising the provinces of Gangani, Vishákpattanam, Rájámatendri, and Maclákpattanam.
2. The **SOUTHERN**, comprising the provinces of Salem, Trinchinapalli, Tanjúr, Madura, Koimbatúr, Tuinevellí, and the territory of the Rájáh of Travancore.
3. The **CENTRAL**, comprising the provinces of Nellúr, Guntur, Chengalpatt, North and South Arkatt.
4. The **MYSORE**, comprising the provinces of Mysore, (or Maisur), Malabar, and Kanara.
5. The **CEDED DISTRICTS**, comprising the provinces of Kadagra, Karmél, and Bellari; and
6. The **PROTECTED STATES**, including Nagpúr and the Nizam's territory.

The soil of the presidency varies greatly. Along the coast it is generally light and sandy; inland, a decomposed syenite is so strongly impregnated with salt that in dry weather the ground glitters with a granular efflorescence; while on the banks of the Coleroon the mould is rich and genial, producing crops of extraordinary luxuriance. A like diversity of climate exists, from the tropical heat of the maritime districts to the grateful coolness of the country at the base of the Neilgherries. The principal products are—date sugar, sugar cane, rice, wheat, barley, maize, and other grains; tamarisk, areca, yam, plantain, mango, melon, and cocoa-nut; ginger, turmeric, tobacco, coffee, indigo, hemp, and cotton. Wild animals are still numerous, notwithstanding the rewards offered by the British government for their extirpation, and include the elephant, tiger, wolf, bear, among the carnivora, as well as the elk, the antelope, the jackal, and the wild hog.

The general aspect of the presidency is that of an elevated table-land, which on either side slopes gradually towards the sea, but on the E. and W. is shut in by the Eastern and Western Ghauts, on the S. by the mountain range of the Neilgherries. The latter shoots across the peninsula from N.E. to S.W. with an average elevation of 5000 feet, and so links together the two great lines of the Ghauts. The main rivers are the Godavery and the Kistna; the

minor streams, the Palaur, Pennaar, Coleroon, Cavery, and Vighey.

The administration of the presidency is in the hands of a governor, who is subordinate to the governor-general of India, and assisted by a council of three members (one being the commander-in-chief), and three secretaries for the financial, political, and military departments. The presidency, for revenue purposes, is divided into twenty-one collectorates. The Anglican church is represented by a bishop and archdeacon, and nineteen chaplains, each with his separate district. The languages spoken are Hindustani, Mahrathi, Telooogo, Tamil, Malayim, and Canarese.

The trade between the United Kingdom and Madras, although considerable and yearly increasing, is by no means so important as that with either of the other presidencies. The following tables show the imports and exports of the principal articles and their values for 1864 :—

IMPORTS INTO GREAT BRITAIN FROM MADRAS.

	Quantity.	Value.
Coffee, . . .	13,864,486 lbs., ...	£439,298
Cotton, raw, .	421,833 cwts., ...	3,695,819
Indigo, . . .	14,450 " ...	295,437
Oil (cocoa-nut),	148,575 " ...	293,128
Rice, . . .	124,993 " ...	64,033
Seed (for express- ing oil therefrom,)	16,722 qrs., ...	42,688
Sugar, unrefined,	228,223 cwts., ...	259,873

MADRAS, a maritime city of British India, capital of the presidency of Madras, is situated in a district of the same name on the Coromandel coast, and in lat. 13° 4' 6" N.; long. 80° 14' E. The natives call it Cheunapatanam, or city of Cheunapgoa, an apocryphal Indian prince. Though the seat of an extensive commerce, its position is most unfavourable for commercial purposes. The roadstead is swept by every wind except the west; the shore is sandy and exposed, without harbour or landing-place, and when a gale breaks out the only chance of safety for ships is to make for the open sea. In calm weather the surf breaks 300 feet from the beach, and gathers in a wave 3 feet in height. When storms prevail it breaks 1000 feet off, with a wave 14 feet high, and the native boats cannot pass it then without imminent risk of life. These boats are built of thin planks, with coir caulking, and are large and light. The fishermen make use, however, of a catamaran, which is formed of two or three logs of wood 8 to

10 feet in length, firmly lashed together, and capable of holding two men. Madras has two seasons, marked by the two monsoons; the north-east, lasting from October to February, a period of violent storms, and the south-west, from May to October. Ships are not allowed to anchor from the 15th October till the 15th December.

The city, with its suburbs, which are nine in number, extends along the coast for nine miles, and occupies a level and ill-drained area of twenty-seven square miles. In the centre, and on the shore, stands Fort St. George, built in 1639, a formidable stronghold, generally garrisoned by an European regiment and two companies of native artillery. Within its precincts are the council house and the civil and military offices. West of the fort is placed an equestrian statue of Sir Thomas Munro, by Chantrey. To the north lies the Black Town, inhabited by few European families, and closely as well as irregularly built. Here are the Seven Wells, affording a plentiful supply of wholesome water. The Government house, St. George's church, the Presbyterian church, and Roman Catholic cathedral, are handsome structures. There are also an university, military orphan asylums, a polytechnic institution, a mint, a medical school, a high school, an observatory, and various charitable associations. St. George's cathedral contains Chantrey's statue of Bishop Heber. The university has a valuable museum and library. North of the fort stands an elegant lighthouse 126 feet high, with a singularly brilliant light.

The commerce of Madras is extensive. Its imports include cotton goods, wines, spirits, metals, sugar, stationery, jewellery, silk, horses, and hardware; its exports, cotton, grains, rice, indigo, coffee, sugar, saltpetre, ginger, and pepper.

Madras was founded by the English in 1639, their first settlement on the coast having been at Armagon, sixty miles to the north. In 1702 it successfully resisted a besieging force under Daoud Khan. In 1744 it was captured by the French, but restored to England in 1749. It was again besieged by the French in 1758, under the celebrated Lally Tollandal, but after an investment of two months he was compelled to retire. It is now the chief seat of the government and judicial administration of the presidency. Nine newspapers are published here, and nearly 13,000 foreign and native vessels annually enter its port. In 1829 its population was computed at 462,951; in 1851, at 720,000; but a more accurate as well as recent enumeration reduces the number to 450,000, of whom not more than 16,000 are Europeans.

MADREPHYLLIÆA (*Cœlenterata*), the first section of the *Stony Zoantharia* of Blainville, who styles the other section of this family *Zoantharia Madreporæa*. The Linnaean genus *Madrepore* included nearly all the species, and obviously required analysis, the more so that geological naturalists referred to the same genus a vast number of previously unknown forms, and thus encumbered recent and impeded fossil zoology, and prevented any right notion of the successive forms of zoophytic life on the globe.

Solander proposed some useful divisions of this unmanageable genus, derived from the growth of the coral; Lamarck established many important genera,

especially characterizing some fossil groups; Lamarck also laboured to improve the classification. Of late years Goldfuss has described additional fossil groups; and M. de Blainville has reorganized the labours of his predecessors, with a special regard to the soft animal parts figured and described by Lesueur, Quoi, Gaimard, and other voyagers.

The *Madrephyllæa* of this writer seldom acquire that highly ramose figure which belongs to the Lamarckian genera *Madrepora*, *Pocillopora*, &c.; they are furnished with cells of various figures, always, however, radiated by lamellæ, which are frequently numerous. There is no general distinctive character of the soft parts or 'polypi,' as they have usually been termed.

MADREPORÆA (*Cæliterata*), the second section of the *Stony Zoantharia* of De Blainville, and placed by him after *Madrephyllæa*.

The Corals of this section are generally arborescent, with small partially lamelliferous cells, and constantly porous in the interstices and walls of the cells. This last is the most important character. The Lamarckian genus *Madrepora* included many of the genera of De Blainville.

MADREPORITE, *Anthracomite*, *Columnar*, *Carbonate of Lime*, is a grayish black translucent mineral, which occurs in roundish masses, and consists chiefly of carbonate of lime and carbonate of magnesia.

MADRID, Department. [CASTILLA-LA-NUOVA.]

MADRID, the capital of New Castile and of Spain, and now also of the province of Madrid, is situated on a bare and exposed plateau, 2060 feet above the sea-level, in the middle of the extensive plain of New Castile, which is bounded on the north by the mountains of Guadarrama, and on the south by those of Toledo, in 40° 24' 18" N. lat., and 3° 42' W. long. Madrid is supposed to occupy the site of the Mantua Carpetanorum of the Romans. It was a frontier town in the time of the Moors, and was constituted the capital of Spain by Philip II. Occupying an area about five miles in circumference, and with a population at the last census of 475,785, it stands on the left or eastern bank of the Manzanares, a small river, which is crossed by two majestic bridges, called Puente de Toledo and Puente de Segovia. The city is surrounded by a brick wall twenty feet high, which contains fifteen gates, mostly built of coarse gray granite.

The general aspect of Madrid from all the approaches is anything but inviting. The numerous fantastic spires of churches and convents, the tiled roofs of the houses, the sterility of the neighbourhood, and the total absence of good houses, pleasure-gardens, or other buildings which indicate the approach to a great city, give to the capital of Spain the most gloomy and forbidding appearance.

The interior, however, is not devoid of beauty. There are wide and well-paved streets, extensive and well-planted public promenades, fountains in many of the squares, gorgeous churches, and handsome public buildings. The houses are large and well constructed. There are forty-two squares, of which the principal are—that of the Royal Palace; that of Santa Catalina, where a beautiful bronze statue of Cervantes has been placed; the Puerta del Sol, where the five principal streets of Madrid meet; the

Plaza de la Cevada, where criminals were formerly executed; and lastly, the Plaza Mayor, which is the finest of all.

The royal palace (*Palacio Real*) though unfinished, is one of the finest royal residences of Europe. The interior is decorated in a style of costly magnificence. It has four fronts, 470 feet in length, and 100 feet high. The custom house; the Casa de Correos (post office) in the Puerta del Sol; the palace called de Buena Vista, formerly belonging to the dukes of Alba, now converted into an artillery museum; the royal printing office in the street of Carretas; and the palace of the duke of Berwick—are among the public and private buildings which adorn the capital. Among the numerous churches and convents which fill the streets of Madrid, scarcely one can be mentioned as a specimen of a pure style of architecture. The public promenades are many; the chief are the Prado, the Retiro, and the Delicias.

Madrid contains a university, nine academies, four public libraries, three museums, three theatres, an amphitheatre for bull fights, and thirty-three public fountains.

The Museo, or Picture Gallery, is open to the public on Sundays and Mondays, and to foreigners on other days on producing their passports. In 1865 it contained 1833 pictures, among which were sixty-two by Velasquez, forty-six by Murillo, ten by Raphael, and a proportionate number by other great masters.

Charitable and benevolent institutions are numerous, and some are amply provided with funds; but the management having always been in the hands of the clergy, the funds have been spent in building monasteries and churches rather than applied to the charitable purposes intended by the donors.

Madrid has little manufacturing industry. A manufacture of porcelain and another of tapestry are both the property of the Crown.

MADRIDEJOS. [CASTILLA-LA-NUOVA.]

MADRIGAL, in Music, is an unaccompanied vocal composition, sometimes in three parts, but commonly in more. The Flemings invented the madrigal about the middle of the sixteenth century, and the Italians took it up shortly after. Palestrina, Marenzio, Mazocchi, and Scarla, in Italy, and Morley, Weekes, Wilbye, Bennet, John Ward, Orlando Gibbons, Dowland, and Ford, in England, were the chief madrigal writers of that century. It is not too much to say that the English madrigalists have no superiors. The art was long indebted to the Madrigal Society, a club which consisted chiefly of amateurs, founded in London in 1741, and which, by zeal and perseverance, succeeded in diffusing throughout the British Isles a taste for a species of music as delightful as it is scientific, and exactly suited to the choral societies already existing or springing up in all our great manufacturing and commercial towns.

MADURA, an island in the Eastern seas, separated by a narrow strait from the north-east coast of Java, with which it is connected under the Netherlands government. Lat. 7° S., long. 113° E. Its extreme length from east to west is 90 miles, and its mean breadth 17 miles. The inhabitants, who reside chiefly in villages, amount to about 522,000. The religion of the Madurese is Mohammedan, although the remains of Hindoo temples attest the prevalence

of that faith in former times. The natives are active, honest, brave, and skilful.

The island is inferior in fertility to Java, and barely supports its population.

MADURA, a littoral district in the presidency of Madras, Hindustan, separated from Ceylon by a channel of varying width, has an area of 10,500 square miles, and a population of 1,775,000. Its natural products are sugar, tobacco, cotton, and betel-nut.

MÆANDER. [ANATOLIA.]

MÆCENAS, CAIUS CILNIUS, belonged to the equestrian order, and was descended from an ancient Etruscan family at Arretium. We are ignorant of the place and time of his birth. He received a good education, and was well acquainted with the Greek language. He early became acquainted with Octavianus (Augustus Cæsar), and continued through his life an intimate friend and chief adviser of that emperor. While Augustus was engaged in opposing Sextus Pompeius, and also during many of his other wars, Mæcenas was intrusted with the charge of the city. Mæcenas is said to have dissuaded Augustus from his purpose of restoring the ancient Roman constitution, which Augustus, however, probably never seriously intended. He died B.C. 8.

Mæcenas was a great patron of literature; and it was principally owing to his assistance and support that Virgil and Horace were raised from indigence, and enabled to devote themselves to poetry. They were both admitted to his friendship, and Horace in particular lived on terms of intimacy with him. He was a man of luxurious habits, and lived in a magnificent house on the Esquiline Hill. He wrote several works, such as poems, tragedies, and a 'History of the Wars of Augustus.'

MAELAR, an extensive lake of Sweden, running inland for about 80 miles from the Baltic, with a breadth varying from 2 to 23 miles. It contains no less than 1300 islands, and its total area is 520 square miles. It has deep and clear water, and is connected with the Baltic by a strait, on both sides of which Stockholm is built.

MAELSTROM, or MALSTROM (Danish, *malström*, 'a whirlpool'), a celebrated whirlpool, off the N.W. coast of Norway, and immediately to the S.W. of Moskenesoe, the most southern of the Loffoden Isles, lat. 67° 48' N. and long. 12° E. It is in reality a violent current, which runs in opposite directions alternately, for six hours at a time, and with a peculiar rotatory motion. Notwithstanding the fables told of its dangerous character, it may be traversed with safety by ordinary sailing boats, except when a N.W. wind beats up against the reflux of the waves. Its depth does not exceed twenty fathoms.

MÆRA, Dr. Leach's name for a genus of amphipodous crustaceans. Example, *Mæra grossimana*, Leach (*Cancer Gammarus grossimanus*, Montagu). Very common on the English coasts, where it is found under stones and rocks at low water.

MAFFE'I, SCIPIONE, MARQUIS, was born at Verona in 1675. He was educated in the college of Parma, and served in the Bavarian army during the war of the Spanish succession. His principal works are—'La Merope,' a tragedy, the first written in Italian which deserves the name; 'Verona Illustrata,' a very valuable work; 'Trattato dei Teatri

antichi e moderni,' a defence of the stage; and 'Gallia Antiquitates.' In union with Vallisnieri and Zeno, Maffei also originated the first literary journal which appeared in Italy, *Giornale dei Letterati*, begun in 1710, and which was continued till 1730. Maffei died at Verona in the year 1755.

MAGADOXO, a town on the eastern shores of Africa, on the Somali coast, is situated in 2° 30' N. lat. and 45° E. long. The harbour is formed by a long coral reef, and the town is divided into two parts—Umarween and Chamgany; but the latter consists entirely of tombs. Umarween contains about 150 stone houses, built in the Spanish style. It carries on some commerce with Arabia. Its exports are ivory, gum, and a particular kind of cloth; it imports sugar, dates, salt fish, arms, and slaves. The town, which is very unhealthy, is inclosed by stone walls, has about 5000 inhabitants, and is governed by the imaum of Muscat.

MAGALHAENS, FERNANDO, incorrectly called *Magellan*, was born about 1470, in some place in Alentejo. He is celebrated for his intrepid expedition, under the patronage of the Spanish crown, to America, when he was the first to discover, in 1520, the strait which bears his name, and the Ladrões and Philippine Islands. At the latter group he died in a skirmish with the natives in 1521. An account of the voyage was written by Pigafetta, who had accompanied him, but except some extracts, it remained unpublished till 1729, when it was given to the public in Italian and in French by M. Amoretti.

MAGALHAENS, STRAIT OF, commonly called the *Strait of Magellan*, is the most extensive known strait on the surface of the globe. Its length in a straight line is above 200 miles; but if the three great bends are taken into the account, it is rather more than 300 miles. It divides the continent of South America from Tierra del Fuego. The eastern entrance is formed by Cape de las Virgines on the continent and by Cape del Espiritu Santo, or Queen Catherine's Foreland, which is on King Charles' Southland, the largest of the islands composing Tierra del Fuego. At its western entrance are Cape Pillar to the south, on the island of South Desolation, and Cape Victory to the north, on a small island belonging to Queen Adelaide's Archipelago. The most northern bend of the strait approaches 53° 10' S. lat., and the most southern inlet, called Admiralty Sound, 55° S. lat. The eastern extremity of the strait is situated in about 68° 20' W. long., and the western in about 74° 40'.

The Strait of Magalhaens was discovered by Fernando Magalhaens in 1520. It was formerly much navigated by vessels bound for the harbours on the western coast of America; but the navigation was always dangerous and tedious, in consequence of the all but continuous western gales, the great strength and irregularity of the currents, the numerous rocks and cliffs in the western part of the strait, and the great humidity of the climate, which engenders scurvy and other diseases. At present a vessel rarely enters the strait unless despatched by some government for a special purpose.

MAGAZINE (Arabic, *Makhzan*), a strong building, constructed generally of brick or stone within a fortified place, or in the neighbourhood of a military or naval station, in order to contain in security the

gunpowder or other warlike stores which may be necessary for the defence of the place, or for the use of the troops who are to perform military duty in the province or district. [BOMB-PROOF; CASEMATE.]

The buildings in which gunpowder is contained are constructed with every precaution necessary to insure dryness. They are generally in places remote from other buildings; they are furnished with metallic conductors, in order to avert danger from lightning; and for security against the attempts of ill-disposed persons, they are surrounded by a wall and ditch. When in situations where they may become the objects of hostile measures, they are made shell-proof. They should always be built to admit sufficient daylight to render the use of lanterns unnecessary.

The great magazines which have been constructed in this country consist of several parallel vaults, separated from each other by brick partition walls, in which are doorways for affording lateral communication. Each vault is about 90 feet long, 19 feet wide internally, and from the floor to the crown of the arch 19 feet high. The side walls are from 8 to 10 feet thick, and are strengthened by buttresses built at intervals against them. The concave or interior surface of each vault, in a vertical and transverse section, is nearly of a parabolical figure, above the springing courses; and the exterior surface has the form of two inclined planes meeting in a longitudinal ridge-line above the middle of the vault. One of the vaults is usually kept empty, so that the gunpowder may be moved from one place to another, a process necessary to keep it in good condition. The thickness of the brickwork forming the vaulted roof is therefore various: at the crown it is 7 or 8 feet, and on the hances about 3 feet, this being considered sufficient to resist the shock of falling shells. Temporary magazines, such as are formed to supply the batteries in a siege, are generally made of wood covered with earth.

On board a man-of-war the magazine is of great strength. It is situated in the hold, and is separated by a transparent screen from the light-room, in which lanterns of a special kind are kept to light the magazine—the introduction of fire in any form into the magazine itself being absolutely forbidden. In case of a fire in the vicinity, the magazine can be immediately flooded.

MAGAZINE is the name given to many periodical publications—generally issued monthly. The oldest is the *Gentleman's Magazine*, commenced in 1731, and still (1866) flourishing. [PERIODICALS.]

MAGDALEN COLLEGE, OXFORD, was founded in 1456, by William of Waynflete, bishop of Winchester and lord high chancellor of England, for a president, forty fellows, thirty scholars called *Demies*, a schoolmaster, an usher, four chaplains, an organist, eight clerks, and sixteen choristers. By an ordinance framed for the college under powers granted by the Act 17th and 18th Vict. c. 81, the statutory restriction of fellowships to certain counties and dioceses is abolished, and ten fellowships are to be suspended, and ten demys to be added to the statutable number. Demys hereafter to be filled up, are to be tenable without reference to place of birth, for five years and no longer. Twenty exhibitions are to be established for deserving persons in need of support at the university: and four professorships (to

be called Waynflete Professorships) are to be founded and maintained within the college in lieu of the lectureships mentioned in the previous statutes. The visitor is the bishop of Winchester. The college has thirty-seven benefices and two perpetual curacies in its gift.

Magdalen College stands upon a plot of ground at the entrance of Oxford from London bounded on its east side by the Cherwell. The buildings are extensive. The entrance-court leads into a larger quadrangle, which contains the chapel, hall, and library. South of the chapel and on the south side of what is called the Chaplain's court stands the tower of the college, the beautiful proportions of which render it one of the chief ornaments of Oxford. The great quadrangle was begun by the founder in 1473, though not finished till after his death. The foundation of the tower was laid in 1492. The foundations of what are called the New Buildings of this college, on the north side of the great quadrangle, were laid in 1733. The chapel, which had been refitted and decorated in an incongruous manner in the time of Charles I., was restored to its former magnificence under the direction of Mr. Cottingham in 1833. (*Oxford University Calendar*, 1866.)

MAGDALEN HALL, OXFORD. The school, with the refectory and chambers erected by Bishop Waynflete for students previous to admission into his college, and adjoining its buildings, obtained the appellation of St. Mary Magdalen Hall as early as 1448, and was governed by one of the fellows till 1602, when it became an independent hall. The president and fellows of Magdalen College, being desirous of recovering this site, obtained, in 1816, an Act of Parliament which authorized them to prepare for the reception of this society Hertford College, which had lapsed to the crown, and the principal and other members removed there on its completion in 1822. This hall is possessed of one benefice; and of several scholarships and exhibitions, all of which are tenable for three years.

MAGDALENE COLLEGE, CAMBRIDGE, was built by Edward Stafford, duke of Buckingham, in the year 1519, under the name of Buckingham House, on the site of an ancient hostel belonging to the abbey of Ely, Ramsey, and Walden. The duke of Buckingham not having completed the building at the time of his attainder, the college fell to the crown, and was granted to Thomas, Lord Audley, lord high chancellor of England. Formerly there were four fellowships on the foundation of the college and fourteen bye fellowships; but by the new statutes no person is hereafter to be elected to any bye fellowship, and there are to be eight open fellowships. It is also declared by the new statutes that (excepting those scholarships and exhibitions, the right of preference to which is preserved to particular schools) all restrictions shall be entirely removed, and the total amount of such scholarships and exhibitions shall form a general fund for open scholarships. This fund shall be so far augmented from the revenue accruing to the college by the abolition of bye fellowships, that there shall be three open scholarships of at least 60*l.*, three of at least 40*l.*, and six of at least 20*l.* a year each.

This college, which stands on the north side of the Cam, consists of two small courts. On the north

side of the second is a stone building, the body of which is appropriated to the reception of the Pepsian Library. This library was bequeathed to the college by Samuel Pepys, Esq., secretary of the Admiralty in the reigns of King Charles II. and King James II. (*Cambridge University Calendar*, 1866.)

MAGDALENA, River. [GRANADA, NEW.]
MAGDEBURG, one of the three governments of the Prussian province of Saxony. Its area is 4446 square miles, and the population in 1861 was 779,784. The government is divided into fifteen circles. The country is one of the finest parts of the Prussian monarchy, consisting chiefly of a fertile and level tract; the hills in the south-west, which are offsets of the Harz, are low, and in other parts the surface is merely varied by gentle elevations.

Magdeburg, the capital of the government and of the province of Prussian Saxony, and one of the strongest fortresses in Prussia, stands on the left bank of the Elbe and an island formed by its arms, in 52° 8' N. lat., 11° 39' E. long., 80 miles S.W. from Berlin. The town consists of three parts, called Altstadt, Neumarkt, and Friedrichs-stadt; and of two suburbs, Sudenburg and Neustadt. It is ill built, with narrow, crooked streets. The most remarkable buildings are—the noble cathedral, which was completed in 1363, the town-hall, the government house, the artillery barracks, and the theatre. Of the squares the largest are, the old market-place, in which is a statue of Otho the Great; and the cathedral square, which is surrounded by handsome buildings and avenues of trees. The town has numerous charitable, literary, and scientific institutions, schools, gymnasia, libraries, and picture galleries. It has also manufactures of silk, broad cloth, leather, gloves, lace, tobacco, jewellery, pottery, beer, spirits, &c. The town has an active trade, facilitated by railways to Berlin, Hamburg, and Dresden, and by steam-packets on the Elbe. Magdeburg is very ancient, dating from the eighth century, and is rich in historical associations; it is the see of a bishop, was at one time a member of the Hanseatic league, and long the capital of an archbishopric, which was secularized at the peace of Westphalia. It suffered during the religious wars of the sixteenth and seventeenth centuries, being sacked and nearly destroyed in 1631. It had sustained a siege of twenty-eight weeks against the Imperialists, under Tilly; and when it was at last taken 30,000 of the inhabitants were butchered. The French took it in 1806, and annexed it to the then kingdom of Westphalia, but it was restored to Prussia in 1814. The civil population of the city and suburbs in 1861 was 78,665; and the military, 7636.

Aschersleben. [ASCHERSLEBEN.]

Burg, 15 miles N.E. from Magdeburg, on the railroad to Berlin, is a busy manufacturing town of 15,000 inhabitants, most of whom are employed in the cloth and tobacco factories.

Halberstadt, an old town with about 23,000 inhabitants, stands on the Holzemme, 27 miles S.W. from Magdeburg, and has manufactures of woollen cloth, tobacco, leather, carpets, gloves, straw hats, starch, and soap, with oil refineries, breweries, and a trade in corn and wool. The chief buildings are the cathedral; the church of Unsere Liebe Frau, which

is built in the Byzantine style, and dates from 1005, but is now not used as a church; ten Protestant and two Roman Catholic churches; a Jews' synagogue; town-house; theatre; college; diocesan and normal schools; public libraries; and private museums and picture galleries. The town is inclosed by walls, outside of which are several suburbs.

Quedlinburg, a walled town, the birthplace of Klopstock, the poet, and Karl Ritter, the geographer, stands on the Bode, 30 miles S.W. from Magdeburg, and has 14,000 inhabitants, who manufacture beet-root sugar, spirits, and woollen cloth. This place was long famous for its convent, the superioress of which was in spiritual matters subject to the pope only, was a princess of the empire, and had a vote in the diet. At the Reformation the abbess embraced the Lutheran religion, and the institution continued, but with greatly diminished means, till 1802, when the convent was sequestered.

Schwitzedel, a walled town 50 miles N.W. from Magdeburg, stands on the Jetze, which divides it into the Old and the New Town. It has six churches, two hospitals, a gymnasium, and 1740 inhabitants, who manufacture woollen stuffs, gloves, needles, beer, spirits, &c.

Schönebeck, 10 miles S.S.E. from Magdeburg, stands on the left bank of the Elbe, and has important salt-works, which yield 672,000 cwts. of salt annually, and 8269 inhabitants, who manufacture tobacco, leather, chemical products, gloves, &c.

Stendal, a walled town, entered by five gates, stands on the Uchte, 35 miles N.N.E. from Magdeburg, and has 8079 inhabitants, engaged in the manufacture of cloth, calico, and leather.

MAGELLAN. [MAGALHAENS.]

MAGENIE, FRANÇOIS, the distinguished anatomist and physiologist, was the son of a physician at Paris, and born at Bordeaux in 1793. He was educated at Paris; and through the interest of his father became the pupil of the celebrated Boyer, and afterwards his demonstrator of anatomy. He was subsequently appointed physician to the Hôtel Dieu; and in 1831 he succeeded to the chair of anatomy in the College of France. He was one of the most skilful and experimental anatomists of modern times; and his various experiments on living animals, to determine the functions and properties of the blood and nerves, have placed him at the head of European physicians. His experiments on the absorption of poisons, such as strychnine, prussic acid, &c., more clearly demonstrated the nature of their action on the animal system. So numerous, and apparently cruel, were his experiments, that the French authorities thought proper to interfere. He was the first to demonstrate successfully that the veins were organs of absorption, and indeed the great agents in the absorption of liquids. He was also a laborious writer, and among other works, produced '*Éléments de Physiologie*;' '*Leçons sur les Phénomènes physiques de la Vie*;' '*Leçons sur les Fonctions et les Maladies du Système Nerveux*;' '*Leçons sur le Sang*,' &c. He was also a contributor to various scientific dictionaries and encyclopædias—as the '*Dictionnaire de Médecine usuelle*;' '*Encyclopédie des Gens du Monde*,' &c. He died in 1856.

MAGENTA, a town and commune of Italy, in the province of Pavia, sixteen miles west of Milan;

population about 6000. It contains four churches—one of considerable size, and manufactures of soap, wax candles, and whetstones. The wine of the district is held in good repute. There is a station near the town on the railway from Turin to Milan.

Magenta was the scene of a great battle in the war which established the independence of Italy. In the spring of 1859 the Austrians had entered Piedmont, and advancing to within a few miles of Turin, occupied the country between the Dora, Sesia, and Ticino, while the Sardo-French army was posted south of the Po, supported by Alexandria and Casale, and receiving supplies from Genoa. Towards the end of May the French emperor suddenly changed his plan of operations, and by a brilliant series of movements turned the right wing of the Austrians, and encamped his army on the west side of the Sesia. On the morning of the 4th of June, the allies, in two great divisions, one under General M'Mahon, and the other under Napoleon himself, moved forward from Turbigo on the north, and Novara on the south, in order to effect a junction at Magenta, and fall with overwhelming force on the Austrians. Napoleon, in crossing the Ticino, met with an obstinate resistance, and the issue seemed doubtful until M'Mahon, successful on his side, brought up his division to the emperor's aid, and advanced on Magenta. About six o'clock the Austrians occupied the town, and bravely defended it for ten hours against the combined forces of M'Mahon, of Canrobert, and of the Imperial Guard, which, after a furious strife, had fought its way from the Ponte Nuovo, each house being defended and stormed as if it were a battery. The arrival of the French reserves compelled the Austrians, though reluctantly, to fall back; and on the morrow, defeated and disorganized, they retired in a southerly direction, leaving open the road to Milan to Napoleon and Victor Emmanuel.

The Austrians lost 13,000 killed and wounded, and 7000 prisoners; the French 3700 killed, and 735 prisoners.

This important victory has recently been commemorated by the erection of a monument on the battle-field. The design was furnished by Signor Giovanni Brocca, and combines in one the purposes of a tomb, a chapel, and a monument. The style is Egyptian as to form, and Lombardian in ornament, with the basement fitted up as a chapel, where mass will be duly celebrated on the anniversaries of the battle. It consists of an imposing obelisk placed upon a solid cubic basement; total height, 65 feet. The sides are ornamented, at one-third of their elevation, with marble bas-reliefs, representing the Emperor Napoleon, Victor Emmanuel, and the principal types of the French army. Above these, on other bas-reliefs, are represented wreaths of laurel and oak, and surmounting an inscription in Italian—'All' Esercito Francese. . . . Napoleone III. e Vittorio Emanuele Alleati. . . . La Riconoscenza e la Pietà. . . . Magenta, iv. Giugno, MDCCCLIX.' (To the French army—Napoleon III. and Victor Emmanuel allied—Gratitude and Piety—Magenta, June 4, 1859.) Near the summit of the obelisk are four openings, with a decoration in the form of a star. These openings, illuminated by a powerful lamp kept burning in the interior, give the monument by night the appearance of a lighthouse; so

that by night, as well as by day, the memorial of Magenta proclaims its purpose and commemorates the brave who perished in the cause of Italian unity, and whose mortal remains are interred in the crypt beneath the basement chapel.

MAGGIORE, LAGO. [LAGO MAGGIORE.]

MAGHERAFELT. [LONDONDERRY.]

MAGI, the name of the priests among the Medes and Persians. The Magi formed one of the six tribes into which the Medes were originally divided (Herodot. i. 101); but on the downfall of the Median empire they continued to retain at the court of the Persian conquerors a great degree of power and authority. The learning of the Magi was connected with astrology and enchantment, and they were held in the highest reverence. No transaction of importance took place without or against their advice; and they exercised the most unbounded influence both in private and public life. In the course of his religious reform Zoroaster reorganized the Magi, and re-enforced their ancient laws, which were very simple and severe, but which had been so far neglected as to allow them to live in indolence and luxury. They were divided into three orders: the Destur Mobeds, or Perfect Masters; the Mobeds, or Masters; and the Herbeds, or Disciples.

MAGIC is the pseudo-art by which the mediæval philosophers professed to obtain a mastery over the secrets of the unseen world, and to communicate with demons and invisible spirits. In a more general sense it includes every species of divination of the future, whether under the names of astrology, necromancy, sorcery, vauderie, or witchcraft; while of late years it has even been made to include the common tricks and sleight-of-hand performances of vulgar conjurors. In its original application it signifies the doctrine of the Magi; because the Chaldean priests were supposed to have gained their extraordinary knowledge, superior wisdom, and remarkable skill from familiar spirits or other supernatural agents. It may therefore be briefly defined as the art, or science, which teaches us to perform various phenomena, and obtain an insight into coming events by the application of mysterious means, known only to the initiated, which command the services and interposition of good and evil spirits.

Magic appears to have had its origin on the plains of Assyria, and the worship of the stars was the creed of those pastoral tribes who, pouring down from the mountains of Kurdistan into the wide level where Babylon afterwards raised its thousand towers, founded the sacerdotal race of the *Chasdim* or *Chaldeans*. To these men were soon allotted peculiar privileges and ascribed peculiar attributes, until, under the name of Magi, they acquired a vast and permanent influence. They studied the heavens with constant vigilance, and closely investigated the qualities and properties of plants and minerals. They were not only priests, but astronomers, physicians, and prophets. Their temples were astronomical observatories as well as holy places; and the legendary Tower of Babel, in the Book of Genesis, is probably but the mythical equivalent of a vast edifice consecrated to the study of the seven planets, or, perhaps, as the *Bab* (court or palace) of *Bel*, to the brilliant star of good fortune alone. Availing themselves of the general adoration of the stars, they

appear to have invented a system of astrology—the apotelesmatic science—by which they professed to decide upon the nature of coming events and the complexion of individual fortunes, with especial reference to the planetary aspects.

In this system of mythology the places of rank and power were necessarily given to the sun and moon. To calculate their daily positions, the heavens were mapped out into constellations, and belted round with the zodiac, which, with its twelve signs, represented the aggregate and distinctive 'residency' of the sun throughout the year. Each 'sign,' or month, was ruled by a god, who superintended his own 'house,' and also controlled, or kept watch over, the corresponding month. Each month was divided into three parts, and each part governed by a deity, so that in all there existed thirty-six, named counsellors, who formed a sort of celestial senate, and half of whom attended to sublunary, half to heavenly affairs. The seven planets were named *interpreters*, because their diurnal course was supposed to indicate the march of human destiny and the procession of mundane events. Saturn, or old Bel, as the remotest planet, was regarded as the most powerful, and worshipped as the chief interpreter. Young Bel (afterwards the Jupiter of Roman mythology), Merodach (or Mars), Nebo (or Mercury), were reputed of the masculine gender; Sin (or the Moon), and Mytilla, Beltis (or Venus), were invested with feminine attributes. Shamus was the Sun-god. These male and female deities controlled the fates of men, the changes of the weather, and even influenced the characters or properties of metals; gold being identified with the sun, silver with the moon, iron with Mars, lead with Saturn, tin with Jupiter. In this belief may be discerned the first faint traces of that alchemical science which deluded so many inquiring minds in a later age.

The Chaldean priesthood was divided into three orders: the *aschapim*, or singers, who exorcised evil spirits; the magicians, sages absorbed in lofty thought; and thirdly, the astrologers, who read the stars. Cicero refers to them as the earliest sooth-sayers, who ascribed miraculous powers to herbs, and wrought miracles by their agency. They also made use of charms or talismans, inscribed with various images and symbols, and, generally, acquired so wide a renown in the 'dark portions of the world,' that the common name of Chaldeans was bestowed upon the astrologers of all nations.

For fuller details of this remarkable sacerdotal order, and of Chaldean religion, the reader may consult Rawlinson's 'Five Great Monarchies,' vol. i.

In Persia, magic assumed a yet more definite development. The Chaldeans had attributed the origin of all things to a great central everlasting fire. The foundation of the Persian system, usually ascribed to Zerdusht, or Zoroaster, was the existence of two antagonistic principles—Ormuzd, the principle of good, and Ahriman, the principle of evil. In Persia, everything associated with science or religion was included under the denomination 'Magic.' The Persian priests were named the Maguse, or Magi; but they did not arrogate to themselves the entire credit of intercourse with the gods. Zoroaster, who was king of Bactria, made some reservations for the sake of exalting the regal power, and taught that

the kings were illuminated by a celestial fire which emanated from Ormuzd. Hence the sacred fire always preceded the monarch as a symbol of his illustrious rank; and Plato says the Persian kings studied magic, which is a worship of their gods.

The same conception of an antagonism between the good and evil principles is visible in the subordinate deities of the Persians. Ormuzd presided over the Amschuspands, or immortal saints, ideal personifications of the solar forms; and Ahriman over the Devs or Dews (hence, perhaps, our word *Devil*), who were supposed to originate all that was dark and evil in nature. To obtain, therefore, the assistance and patronage of the Amschuspands, and to escape the maleficent influence of the Devs, was the great object of the religious observances of the Persians. When the Greeks obtained some knowledge of these mysteries, they misrepresented and misunderstood their meaning; mistook the prayers of the priest for the invocations of the enchanter; transformed religion into 'magic,' and magi into 'magicians.'

It was in Egypt that magic received its development as an art. That strange and weird land was the cradle and nursery of the sciences, which, at the outset, were mainly applied to magical purposes. Religion here was intimately associated with medicine, or the healing science; the temples were the first hospitals; and the sick were employed as agents to reveal the wishes of the gods. 'The Egyptians declare,' says Diodorus, 'that Isis had rendered them great services in the healing science, through the curative methods which she made known to them; that now, having become immortal, she takes a singular pleasure in the religious services of men, and specially occupies herself with their health; and that she assists them in dreams, thereby manifesting her peculiar benevolence. This is proved, not by fable, as among the Greeks, but by veritable facts. In reality, all nations of the earth testify to the power of this goddess in regard to the cure of diseases by her influence. In dreams she reveals to those who are suffering the fittest remedies for their ailments, and by implicit obedience of her orders, invalids have recovered—contrary to the expectation of the world—who have been given up by all the physicians.'

The most famous temples in Egypt were those of Isis, at Memphis and Busiris; of Serapis, at Canopus, Alexandria, and Thebes; of Osiris, of Apis, and Phtha. Isis, the wife of Osiris, derives her name, it is said, from the Coptic word *isi*, or plenty, and would seem to typify the earth; but she is usually represented as the goddess of the moon (*σελαβήγος*, 'the horn-bearing.') Isis was also employed as a personification of wisdom, and to a certain extent she may be regarded as a symbol of the eternal will, her shrines bearing the enigmatic inscription—'I am the all that was, that is, that will be; no mortal can raise my garment.' Horus was the son of Isis, and instructed by his mother in the art of healing. Horus, synonymous with Light, is the king or spirit of the sun.

Apis was another divinity, worshipped under the guise of a spotted ox. Phtha was the eternal spirit, the creative essence of all things; and his symbol was the everlasting fire of the temples, which burned both day and night.

Finally, Thout, Thot, or Tacut, was worshipped as a god, whom the Greeks call Hermes, the inventor of all arts and sciences, and Trismegistus, or Thrice-great. All historians agree that he was a friend and associate of Osiris; that he taught the Egyptians the useful arts and sciences; and that he deserves a prominent place among the physicians who have received divine honours.

Astrological science was earnestly and eagerly studied by the Egyptian priests. It was their belief that the different stars exercised a powerful influence on the human body. Their funeral ceremonies may be quoted as an illustration, for they agree in sharing among the divinities the entire body of the dead. To Ra, or the Sun, they assigned the head; to Anubis, the nose and lips; to Hathor, the eyes; to Selk, the teeth; and so on. To ascertain the nativity, the astrologer had only to combine the theory of the influences thus exercised by these star-related gods with the aspect of the heavens at the moment of an individual's birth. It was an element of the Egyptian, says an eminent authority, as well as of the Persian astrological doctrine, that a particular star was interested in the natal hour of every human being; and the prevalence of this belief, even in the Christian community, is shown by the legend of the Magi, who had seen the birth-star of our Saviour in the East, and had followed its guidance till they arrived at his home in Bethlehem. In Egypt, as in Assyria, the chemical properties of bodies were referred to divine or sidereal influences. The shores of the Nile were the classical country of chemistry, or rather of alchemy; and the false and the true science equally derive their name from *Chemi*, the 'Black Land.'

Through the instrumentality of Orpheus, Musæus, Pythagoras, and others, who had travelled in Egypt, and been initiated by the priests into their mysteries, magic found its way into Greece, and there assumed various novel developments. It lost much of its religious, and gained more of a romantic character. 'The lively imagination of the Greeks,' as the writer of this article has elsewhere remarked, 'was not content with ascribing the operations of nature to the power of unseen divinities, but made all nature divine; planted a deity in every river, an immortal being in every grove, every fountain, every murmurous rill. Instead of elevating man to the gods, it brought down the gods to man, and placed their celestial hall among the clouds that gathered on the summit of the fabled Olympus. The free spirit of the Greeks revolted from the theocracy of Egypt, from its mysterious omnipotent priesthood; but their quick, keen intellect penetrated as eagerly as the graver wisdom of the Chaldeans into the science of the starry influences, and the relations existing between the human and the divine.'

The Greek sorcery was chiefly manifested in the peculiar rites of the Orphicotelesta, the invocation of the dead, the cave of Trophonius, the oracles of the gods, and the worship of Hecate. The latter mysterious deity—the moon-goddess—was the patron divinity of the sorcerers. From her, as from one of the powers of the nether world, proceeded phantoms that taught witchcraft, hovered among the tombs, and haunted crossways and places accursed by the blood of the murdered or the suicide. 'The Mormo,

the Cereops, the Empusa, were among the goblin crew that did her bidding.' 'Accompanied by the souls of the dead, the terrible goddess, with her ever-changing form, wandered over the earth, while the howling and whining of dogs announced her approach. She presided over the rites of purification and expiation; reptiles and loathly animals and all repulsive mixtures were associated with her service. The vervain and the root of the rue were hers, myrrh and storax flavoured the lizard mast set in her honour under the crescent moon, when, constrained by some barbarous spell or archaic word of power, she revealed herself in dream to her expectant adorsers.'

From Greece we pass on to Rome, which borrowed her magic, no less than her art and literature, from poetic Hellas. The occult science does not appear to have been known to the Romans until about 200 years before the Christian era. But they had previously cultivated a modification of the Etruscan sorcery, comprising the divination of the future, the worship of the dead, the evocation of their *lemures*, or phantoms, and the mystic ceremonies of the Mana-Genita, a nocturnal goddess of awful character. Numa was the great teacher of the ancient Roman magic, which probably partook both of a religious and medical character.

The Christian church, at the outset of its history, forbade the practice of pagan magic, but taught what may be described as a magic of its own. Both Origen and Tertullian held that mania and epilepsy were produced by the action of demons or evil spirits confined within the bodies of the sufferers, and that these were to be exorcised by certain forms of words. The church formally recognized the efficacy of exorcism in 367, when the council of Laodicea ordained that only those should practise it who were duly authorized by the bishops. Connected with magic and magical rites were the supposed curative properties of the relics of saints, and the divine origin popularly ascribed to visions and ecstatic trances. Eclipses, meteors, hurricanes—these were considered portents of war, revolution, and pestilence. On the eve of any great political convulsion the spirits of the dead roamed the affrighted cities. A spell was supposed to rest in holy water; wounds were healed by the recital of the Lord's prayer; and the events of the future were foretold by casual reference to texts of Scripture.

Such was the magic embraced by the great body of the people. The educated classes accepted the graceful conceptions of the Neo-Platonists, and proclaimed the existence of a world of intermediate beings, who could be rendered obedient to man by the utterance of certain mysterious spells. From the *Timæus* of Plato they borrowed the idea of the macrocosm and microcosm. From Pythagoras they obtained their notions of the properties and character of demons. They asserted the sympathy of the human body with the earth, and with miraculous powers inherent in pictures and statues. Finally, they attributed great virtue to the use of certain words in the evocation of spirits.

In the middle ages—to quote again from ourselves—magic asserted its supremacy over the whole of Christian Europe; but it had entirely lost the religious character communicated to it by the Chal-

deans. It had degenerated into the 'Black Art.' It dealt only with the night-side of nature, with the Evil One and his imps, with the loathsome practices of witchcraft, and the enchantments of the necromancer. The scholar rose superior to this low kind of theurgy, but he, too, no longer sought communion with the 'heavenly powers'; he devoted all his energies to the discovery of the philosopher's stone and the elixir of eternal youth—to the sources of illimitable wealth and endless life. The philosophical aspect of the pure magic was entirely lost, and a purely chymical science rose as its substitute. Not the Chaldean magic but the Arabian alchymy occupied the minds of the subtle and laborious. And at this epoch all Christendom was involved in so dense a darkness, so thick an obscurity of ignorance, that the least flash of intellectual light endangered the life or liberty of the enlightened, and drew down upon them the suspicions of the vulgar and the hate of the bigoted. So it happened that magicians and heretics in due time became regarded as synonymous terms. The student who had obtained some insight into the mysteries of science was also denounced as a sorcerer. It is true that the pretensions of the enchanter were universally credited, but his position was full of danger; and while, on the one hand, he was frequently entertained at the table of princes, on the other, he was occasionally burned at the stake. In spite of these perilous results the superstition was never in want of students and professors, who felt a huge delight in their own delusions, and loved to practise on the fears and credulity of the vulgar. They studied the phantasies suggested by the novelties of optical science; made use of ventriloquism, of narcotic drugs, and stupefying fumes. 'All that could impose upon the imagination and subdue the will was called into requisition by the sorcerer to terrify and beguile his dupes. Thus, then, magic gradually passed out of the sphere it had originally occupied, became the enemy instead of the servant and assistant of the priesthood; and except in that abortive revivification of Neo-Platonism which we call Rosicrucianism, was suffered by the scholar and the philosopher to become an instrument of imposture in the hands of the charlatan.'

Nowadays, there survives of the ancient magic only its shadow. Professors of astrology occasionally advertise themselves, and their dupes sometimes make public the deceptions by which they have suffered; but an active and earnest world has no time for the fancies and the fables which exercised so powerful an influence over our forefathers. Mesmerism and electro-biology are but sorry substitutes for magic; and the tricks of the Davenport Brothers may not be compared with the achievements of the mediæval necromancers.

Having sketched thus briefly the history of the rise and decline of the magical art, we must limit our concluding notices to the two important topics of witchcraft and Rosicrucianism.

Rosicrucianism, which we have already described as a modification of Neo-Platonism, appears to have been first preached in Europe by Christian Rosencreutz, or 'Rose-Cross,' a German philosopher. While travelling in the Holy Land he is said to have fallen ill at a place called Damear, and being hospitably entertained by some Arabian philosophers, obtained

from them the germs of the pseudo-philosophy now identified with his name. He returned to Europe in 1401, and attracting a select band of disciples, initiated them into the new doctrines, binding them by oath to keep them secret for a hundred years. Rosencreutz died, it is said, in 1484. But it is certain that some of the Rosicrucian tenets are derived from the well-known quack, enthusiast, and physician, Paracelsus, who asserts the existence of a race of invisible beings, subordinate to the angels, and superior to man, but acknowledging the control of the possessors of the philosopher's stone.

Rosicrucianism was first revealed to the outer world by one Johann Valentine Andrea, a German scholar, born at Herrenberg, in the duchy of Wurtemberg, in 1586. His writings created a great commotion in Germany and England, and a crowd of enthusiasts hastened to enrol themselves in an order whose members possessed such wonderful privileges. Michael Mayer, a German physician of repute, claimed for the fraternity the most extraordinary endowments. They were gifted, he said, with all the graces of nature, which, at their pleasure, they could bestow upon the rest of mankind. To hunger and thirst, to the attacks of disease, to old age and to the usual afflictions of humanity, they were indifferent and impenetrable. Their contemplations surpassed all that had been conceived by the greatest minds since the creation of the world. They were destined to effect the regeneration of man before the end of time arrived. Wisdom and virtue they possessed, as might be supposed, beyond all their fellows. A volume belonged to the fraternity wherein could be read all that had been, or ever would be, written. They controlled the most powerful spirits and demons, and could render themselves invisible to mortal eyes.

Such were the pretensions of the more extravagant Rosicrucians, but the order included some able and earnest men who were simply the disciples of a new kind of mysticism, and concealed their theories under the cloak of an allegorical and symbolic language. It was their object to revive the doctrines of the Neo-Platonists, of such men as Pselus, Plotinus, and Iamblichus, and to investigate, as closely as might be, the secrets of universal nature. They aimed at holding converse with the spirits of the other world, at annihilating the obstacles of time and space, at penetrating to a knowledge of the operations of natural forces, at repressing the sensual in man and developing the psychical, so that the human intellect might hope to comprehend the inner voices of heaven.

Rosicrucianism has not been without a powerful literary influence. It suggested the sylphs and gnomes of Pope's 'Rape of the Lock'; the exquisite Ondine of La Motte Fouqué; Sir Walter Scott's White Lady of Avenel; and much of the imagery of Goethe's 'Faust' and Bulwer Lytton's 'Zanoni.'

Among its most eminent professors have been Robert Fludd, John Heydon, Jacob Böhme, Cornelius Agrippa, Trithemius, and Dr. Dee.

Witchcraft in Europe appears to have originated in the superstitions that rapidly grew up around the simple faith of the primitive Christians. The idea of demonology, familiar to the Mohammedan nations of the East and the tribes of Northern Europe, was engrafted upon Christianity. The evil principle was invested with the personality of Satan, and the 'fallen

stars of the morning' were transformed into inferior demons, resembling the Teutonic fiends in their attributes and character. They were also clothed with various circumstances of grotesque horror, drawn from classic fable. The existence of these maleficent beings once determined, and their relations to humanity, the theory would soon arise that they might be rendered subservient to the will of man, and here Paganism was again drawn upon for the rites of the ancient enchanter. The adventurers who professed to control Satan and his devils received the name of *witches*, from *wekkan*, 'to prophesy,' or when of the male sex, of wizards or warlocks. They loved to injure and ruin their fellows; to curse them with misfortunes, loss of money, loss of life, murrain among their herds, and death in their households. The whole character of mediæval witchcraft was cruel and sanguinary, and no grosser or filthier creed ever led captive the ignorant. In course of time it became the object of a pitiless persecution, and every pretended or supposed witch was hunted to the death. The accusation of witchcraft enabled Philip Augustus to destroy the Knights Templars, and as a witch Joan of Arc is supposed to have been burned. The trade of 'witch-finding' became a profitable one, and many an innocent woman who had incurred the hatred of her neighbours was doomed to a painful death by a mercenary informer. [WITCHCRAFT.]

For fuller details upon the important questions connected with magic, the reader may consult Ennemoser's *History of Magic*; Wier, *De Prestigiis Demonum*; Naudé, *Lives of the Magicians*; Lenglet du Fresnoy; Maury, *La Magie et L'Astrologie*; Godwin, *History of the Necromancers*; Scott, *History of Witchcraft*; Wright, *Narratives of Sorcery and Witchcraft*; Salverte, *Philosophy of Magic*; Adams, *Dwellers on the Threshold*; Colquhoun, *History of Magic*; Levi, *Dogme et Rituel de la Haute Magie*; and the works of Paracelsus, Dr. Dee, Robert Fludd, Comte de Gabalis, &c.

MAGIC LANTERN is a species of lucernal microscope, invented by Kircher, its object being to obtain an enlarged representation of figures on a screen in a darkened room, by means of the pencils of light issuing from a lamp or candle and passing through a convex lens.

The instrument consists of a lantern, generally of tin, and of a cubical form, in the interior of which is the light; and at a perforation in one of the sides is applied a tube, projecting horizontally from it, which carries two glass lenses.

A groove in front of the lantern and parallel to that front receives a rectangular frame containing the glass plates on which are painted, with transparent colours, the objects of which an enlarged view is to be obtained.

A remarkable improvement in the manner of employing the magic lantern was first exhibited in London in the year 1802. The lantern itself was similar to but larger than that which served for more general purposes, and the images were represented on a transparent screen, which was stretched in a vertical position across a theatre or an apartment; and this being made quite dark, the spectators occupied the space in front of the screen, while the apparatus was disposed on the opposite side.

All light was excluded both before and behind the

screen, except that which, in proceeding from the lantern, produced the image to be observed; and the screen being itself invisible, the spectators could scarcely divest themselves of the idea that they were looking into a dark cavern, in which the objects appeared to be gradually advancing towards or receding from them. The illusions produced caused the name of *Phantasmagoria* to be applied to the apparatus. The introduction of the lime light has of late years much improved the effect of objects exhibited by the magic lantern.

MAGIC SQUARE. This term is applied to a set of numbers arranged in a square in such a manner that the vertical, horizontal, and diagonal columns shall give the same sums. Such arrangements were known very early to the Hindoos, Egyptians, and Chinese, among whom, as also among the Europeans of the middle ages, a belief existed that such squares had astrological and divinatory qualities. Emanuel Moschopolus, of Constantinople, wrote on them in Greek in the middle of the fifteenth century. (See Montucla's 'History,' vol. i. p. 346; 'Encyclopédie Méth.,' art. 'Quarrés Magiques;' Hutton's 'Dictionary;' and the 'Mathematical Recreations' of the same author.)

The following is a sample of a magic square:—

2016	4212	1656	3852	1296	3492	936	3132	576	2772	216
252	2052	4248	1692	3888	1332	3528	972	3168	612	2412
2448	288	2088	4284	1728	3924	1368	3564	1008	2808	648
684	2484	324	2124	4320	1764	3960	1404	3204	1044	2844
2880	720	2520	360	2160	4356	1800	3600	1440	3240	1080
1116	2916	756	2556	396	2196	3996	1836	3636	1476	3276
3312	1152	2952	792	2592	36	2232	4032	1872	3672	1512
1548	3348	1188	2988	432	2628	72	2268	4068	1908	3708
3744	1584	3384	828	3024	468	2664	108	2304	4104	1944
1980	3780	1224	3420	864	3060	504	2700	144	2340	4140
4176	1620	3816	1260	3456	900	3096	540	2736	180	2376

The methods which have been given for the formation of magic squares are divided into different rules, according as the number in each side is odd, evenly even, or oddly even. A general method which shall apply to all cases is yet wanting. For a full account of these rules see Hutton's *Mathematical Recreations*.

MAGILUS, De Montfort's name for a genus of testaceous molluscs, the form of whose shell varies very much, according to its different stages of growth, and the circumstances in which it is placed. Example, *Magilus antiquorum*.

MAGINDANAO. [PHILIPPINES.]

MAGISTRATE, a word derived from the Latin *magistratus*, which contains the same element as *magnus* and *magister*, and signifies both a person and an office. A Roman *magistratus* is defined to be one who presides in a court and declares the law, that is, a judge. The kings of Rome were probably the sole *Magistratus* originally, and on their expulsion the two consuls were the *Magistratus*. In course

of time other offices, as those of prætor and ædile, were created; and those who filled these offices were elected in the forms prescribed by the constitution. The original notion of a magistratus, then, is one who is elected to an office, and has jurisdiction.

In England the term magistrate is usually applied to justices of the peace in the country, and to those called police magistrates, such as there are in London, though the term is also properly applicable to the sheriff and the coroner. It has also been applied in other ways; for instance, people have sometimes said that the king is the chief magistrate in the state. But these applications of the term do not agree with its proper sense. A Roman magistratus was elected, and so far he differed from an English justice of the peace; he also exercised delegated power in his jurisdiction, in which respect, as well as being elected, he differed from the king of England, who is not elected, and does not exercise delegated jurisdiction, but delegates jurisdiction to others.

In Scotland this term, though in a strict sense applicable to all persons in authority, is generally employed in reference to the provost and bailies of burghs. These officers have both a civil and criminal jurisdiction within burgh. In civil matters they have cognizance of all debts and questions of possession among the inhabitants; and royal burghs are believed to have the same civil jurisdiction within the burgh as the sheriff has in his territory. (Ersk. i. 4, 21.) Their criminal jurisdiction, however, is now very limited, and extends only to cases of petty riots and matters of police; but where a royal burgh possesses a grant of sheriffship or regality [LORDS OF REGALITY] it enjoys a jurisdiction, not only civil but criminal, as ample and extensive as sheriffs now have or lords of regality formerly had. The magistrates of burghs have also right, with consent of the town council, to impose assessments upon the inhabitants for the use of the burgh. Magistrates are elected by and out of the town council for the time being, the councillors being chosen from the whole body of electors residing or carrying on business within burgh.

MAGLIABECCHI, ANTONIO DA MARCO, born at Florence in 1633, was an indefatigable reader, and had a prodigious memory. He employed his scanty savings in buying books, and gradually collected a vast library, which after his death became the property of the city of Florence. Magliabecchi left no work of his own. Some of his letters have been published in various collections. He died at Florence, in 1714, eighty-one years of age.

MAGNA CHARTA. If the Magna Charta granted by King John did not properly found the liberties which the English nation enjoys, or if it was not the original of those privileges and franchises which the barons (or the chief tenants of the crown, for the names are here equivalent), ecclesiastical persons, citizens, burgesses, and merchants enjoy, it defined them, it formed in its written state a document to which appeal might be made, under whose protection any person who had any interest in it might find shelter, and which served, as if it were a portion of the common law of the land, to guide the judges to the decisions which they pronounced in all questions between the king and his subjects.

Besides the great charter, there was granted at the

same time a charter relating to the forests only. The rights of the church were also secured by the great charter.

The provisions of the Magna Charta are numerous, and some of them have fallen into desuetude. The substance of the Great Charter is given by Blackstone in his 'Commentaries,' who also wrote a treatise on it.

King John was compelled to grant the charter by an armed force, consisting of a very large portion of the baronage, which he was unable to resist. The charter was sealed in the open field, at a place called Runnymede, between Windsor and Staines. The memorable day was June 5, 1215.

The late Record Commission caused to be engraved and published an exact fac-simile of the charter, from a copy preserved in the archives of the cathedral church of Lincoln, with others of the greater charters. In the first volume of their work, entitled 'The Statutes of the Realm,' these charters are all printed, with English translations.

MAGNA GRÆCIA, or MAJOR GRÆCIA, a term used to designate the south of Italy, which contained many flourishing Greek colonies. It does not appear to have been applied to the country north of Cuma and Neápolis.

The time in which the name of Magna Græcia was first applied to the south of Italy is uncertain. It is used by Polybius and subsequent Greek and Roman writers.

MAGNESIA. [MAGNESIUM.]

MAGNESIA, MEDICAL PROPERTIES OF. Oxide of magnesium, termed also, from the mode of procuring it, calcined magnesia, or *Magnesia usta*, is an alkaline earth, possessing the usual qualities of alkalies in their habitudes with acids, and likewise the property of exciting generally purgative action of the intestines. This last-mentioned power gives it a distinctive character among alkaline remedies, as it can be employed not merely to counteract acidity, but also to remove the exciting cause when that consists in the presence of crude or undigested acid-yielding materials in the stomach. Its action as a purgative seems mainly to depend upon its meeting with acids in the stomach, and so forming soluble salts. When these are not present, the magnesia remains undissolved, and if used repeatedly may accumulate in the intestines, and, becoming agglutinated by the mucous secretions, give rise to much uneasiness. When, however, acidity exists, either along with constipation or diarrhœa, more particularly in children, from the milk disagreeing, or from a diet unsuited to their delicate organs of digestion being forced upon them, magnesia is a very proper medicine, especially as it appears to possess a specific power of diminishing gastro-intestinal irritation. It is generally expedient to add rhubarb to it, and combine it with some carminative. In such a state of combination it is peculiarly useful in what is termed diarrhœa crapulosa, arising from too great a mixture or too large a quantity of food.

Sulphate of Magnesia, or *Epsom Salts* ($Mg\ O, S\ O_3 + \cdot 7\ Aq$), in the ordinary form, as met with in the shops, are small acicular crystals. This renders them liable to be confounded with those of oxalic acid, to avoid which the sulphate may be dissolved, and by re-crystallization they are obtained in large

four-sided prisms, or four-sided pyramids. It is soluble at 60° in three times its weight of water.

Sulphate of magnesia is a convenient antidote in cases of poisoning by the salts of lead or barytes.

MAGNESIA ALUM, *Magnesian Pharmacolite*, and *Magnesite*, are three naturally formed minerals, in which magnesia is a chief element.

MAGNESIAN LIMESTONE, a component element in the new red sandstone system. This rock is seen to greatest perfection in England between the rivers Tyne and Tees, between the rivers Wharf and Dun, and between this last river and Nottingham. When crystalline, it is called *dolomite*. Its mode of aggregation varies extremely. In many situations (Thorp Arch, in Yorkshire) it is a soft powdery stone traversed nevertheless by veins of calcareous spar; about Tadcaster, and generally between the Nid and the Dun, it is a firm though hardly compact rock, often traversed by sparry veins and full of irregular crystallized cavities. The crystals are generally carbonate of lime, sometimes mixed with oxide of iron. Farther south the stone becomes more crystalline in its character. The general colour of the magnesian limestone (lower portion) is white, yellow, rich pale brown, or reddish. The upper rock is commonly of a gray, smoky, or purplish hue, and is usually interstratified with thin clay partings; the lower one very rarely.

Various authorities have clearly distinguished the most common organic fossils of this rock. We shall only observe here that, in respect of fishes (*Palæoniscii*, &c.), mollusca (*Producta*, *Spirifera*, &c.), and zoophyta (*Retepora*, &c.), this rock shows an extreme analogy with the carboniferous system. Its place, by mineral analogies, may be rightly fixed in the poecilite system; but by the affinities of organic existence it will be classed with the more ancient rocks.

MAGNE'SIUM (Symbol, Mg), a peculiar metal, of which magnesia is the oxide. Its existence was first demonstrated by the electro-chemical researches of Sir H. Davy. Magnesium is of a white colour, like silver; its lustre is metallic and brilliant; it is very malleable, and fuses at a red heat. When heated to redness in the air or in oxygen gas, it burns brilliantly, and, combining with oxygen, becomes magnesia. In chlorine gas it burns spontaneously.

Oxygen and *Magnesium* (Mg O) form the oxide, or *Magnesia*. Specific gravity, 3.65. It is colourless, inodorous, and tasteless, if pure; it is very nearly insoluble in water, although when moistened it exhibits the alkaline property of turning vegetable yellows brown. *Chlorine* and *Magnesium* (Ch¹ M¹) form a transparent colourless mass; it is inodorous, intensely bitter, very deliquescent, and soluble both in water and alcohol. This salt is one of the saline ingredients of sea water. *Bromine* and *Magnesium* form small acicular crystals, which have a sharp taste, are very deliquescent, and soluble both in water and alcohol. *Fluorine* and *Magnesium* unite when magnesia is dissolved in hydrofluoric acid. The compound formed is insoluble in water, or in hydrofluoric acid, and is not decomposed by a red heat. *Iodine* and *Magnesium*.—A compound of these is obtained when magnesia is dissolved in hydriodic acid; it is very soluble in water, and known only in solution.

Magnesia, or *Oxide of Magnesium*, combines with

most acids to form salts, and also forms a *hydrate*. This hydrate is a saline compound, white with a greenish tint, foliated, and easily splits into thin flexible laminæ. It has a pearly lustre, translucent on the edges. It is composed of about 31 water and 68 magnesia, with a little oxide of iron and manganese. *Nitric acid* and *Magnesia* readily combine, and yield nitrate of magnesia (Mg O, NO₅ + 6 Aq). The solution is colourless, and extremely bitter. *Carbonic acid* and *Magnesia* form carbonate of magnesia, which has a yellowish white colour, with a flat conchoidal and sometimes earthy fracture. It is opaque and very difficult to break. It combines with the hydrate to produce the carbonate of magnesia used in medicine. *Sulphuric acid* and *Magnesia* constitute the salt long and well known by the name of *Epsom Salts*, having been first obtained from a spring near the village of Epsom, in Surrey. [MAGNESIA, MEDICAL PROPERTIES OF.]

MAGNET (derived from the Greek *μάγνης*) is a metallic body possessing the remarkable property of attracting iron and some other metals. It is said to have been found abundantly near Magnesia in Lydia, from which circumstance its name may have been derived. The attracting power of the magnet was known at a very early period, as references are made to it by Aristotle, and more particularly by Pliny. When found native, it is generally a heavy ferruginous ore of a dull grayish colour, but the ores of cobalt and nickel also frequently possess the magnetic properties.

The universal law, that reaction is coexistent with action, implies, that iron must react on the magnet; and it is evident that all the iron in the mass of the earth must act upon a magnet. It is also now known that electrical currents influence magnetic bodies [ELECTRO-MAGNETISM], while heat has an influence on magnetic intensity. Hence it follows as a mechanical consequence, that if a magnetic needle or cylinder be suspended by its centre of gravity, so as to be free to move in any direction round that point, it will not take an arbitrary position like unmagnetized bodies, but must take a specific direction, namely, that which represents the resultant of all the magnetic forces to which it is subject. [DECLINATION OF THE MAGNETIC NEEDLE].

One essential property by which a magnet differs from soft iron under the magnetic influence is this:—If we separate a magnetic bar into any number of minute parts, each such part will be endowed with polarity, similar to the whole; the position of those poles, or foci of greatest attraction, is permanent in a magnet of a given form; but in soft iron it will change when the distance of the iron from the influencing magnet is altered. [MAGNETISM; MAGNETIC INTENSITY.]

During a thunder storm, the poles of a magnet are frequently inverted; the appearance of the aurora borealis is often attended with vibrations of the compass needle, to the extent of several degrees. The actual mode in which the aurora is produced being unknown, it is impossible to decide whether the aurora is itself the cause of this magnetic phenomenon or whether both are attributable to some unknown common cause.

MAGNETIC INTENSITY. When a magnetic needle is freely suspended by its centre of gravity

it is then acted on by all terrestrial bodies containing the magnetic fluids. The direction of the resultant of all such forces in the earth may be regarded as possessing parallelism throughout the extent of the needle, and the latter acquires in consequence a like direction in the plane of the magnetic meridian, of which the position becomes in this manner known.

When a magnet is brought near a needle thus suspended, if the number of vibrations performed by the latter in a given time be observed, it will be found, by an investigation similar to that which is used for a common pendulum, that the intensities of the attractive and repulsive forces vary inversely as the squares of the distances; but it is now known that those intensities become inversely proportioned to the distances simply, when the distances are less than one-eighth or one-fourth of an inch. For the action of the earth on a suspended needle, see TERRESTRIAL MAGNETISM.

The balance of torsion has occasionally been used to discover the relative intensities of magnetism as distributed in bodies; in straight and narrow laminae it has been found by Coulomb to be nearly proportional to the square of the distance from the middle point.

MAGNETISM. If we take a natural or artificial magnet, and spreading over a piece of paper a quantity of fine iron filings, place the magnet on the paper, on taking it up we shall find that the iron filings are attached to it in some degree over all its surface, but they will be principally accumulated at two points situated near the ends of the magnet: these points are called the poles of the magnet. Sometimes, when a magnetic bar is rolled amongst iron filings, we may find several such points along the bar; the magnet is then said to have consecutive points. When a magnetized needle is suspended horizontally on a pivot armed with agate, it assumes a particular direction, nearly north and south. The pole N, at the north extremity of the needle thus adjusted, is commonly called the north pole of the needle; the other, S, the south pole; though the contrary names would be more correct in connection with the theory of magnetism.

If we now bring a piece of soft iron near the pole N, it will be attracted to that pole and become attached to it, so that the exertion of a mechanical force is necessary to separate them. In this way a magnet held vertically will sustain a piece of iron, provided the weight of the iron does not exceed the magnetic force. The pole S has a similar attractive power on iron; the cause of this attractive power is called *Magnetism*. (Plate 1, figs. 1, 2.)

The force of magnetism is exerted without alteration through substances which are not magnetic, and the same is true with respect to the electrical forces when non-conducting bodies are interposed in the direction of their action. On the other hand, the effect of the magnetic forces is considerably modified when substances which are capable of becoming magnetic by influence are situated near the magnet; and a similar effect takes place by the decomposition of the neutral electricities when under the influence of an electrized body. [ELECTRICITY].

In order to observe the action of magnets on each other, make two magnets or magnetic needles to float on water, distinguishing the poles of one by N

and S, and of the other by N' and S'. Bring either the pole N near to N', or S to S': the needles or magnets will separate to a greater distance, and with the greater energy the nearer these poles are placed to each other. On the contrary, if we bring N and S' near each other, the needles will approach and unite those points; and the same happens when the points N' and S are made contiguous: hence this law—*Magnetisms of the same name are mutually repulsive; those of contrary names are mutually attractive*. In the article ELECTRICITY, it has been shown that the same law is true with respect to the two electricities.

The magnetism predominant at the north pole of a needle is called *Austral Magnetism*, and that which predominates at the south pole is termed *Boreal Magnetism*. The quantities of the austral and boreal magnetic fluids in all magnetic bodies are equal; for when we bestow magnetic qualities on iron or steel by the influence of loadstones, hammering, sudden cooling in the magnetic meridian, &c., no new magnetism is communicated; but the natural magnetisms, which previously neutralized each other, are now decomposed. Again, if a magnetic needle be freely suspended by its centre of gravity, the action of terrestrial magnetism produces no linear motion, but only imposes a direction on the magnetic axis; now all the boreal fluid in the globe attracts all the austral fluid of the needle, and *vice versa*, while the like fluids in both repel: hence a motion of progression would be generated, unless the resultant of the repulsive forces on the needle was exactly equal and of an opposite direction to the resultant of all the attractive forces; and the rotatory motion of the needle shows that the points of application of these forces are different; but the intensity of terrestrial magnetism may be regarded as uniform throughout the extent of the needle, and its direction parallel. In order, therefore, that the resultants should be equal and contrary, the sums of the boreal and austral forces of the needle must be equal. In this respect magnetism resembles the natural electricities of all substances.

If we place a bar of soft iron, suspended by a collection of silk strings at its middle, in a direction parallel to the magnetic axis of the dipping-needle, the action of terrestrial magnetism will have full effect on the bar, its natural magnetisms will be decomposed, and it will acquire a polarity similar to that of the needle, its poles repelling the similar poles of the needle, and attracting the contrary poles. If the bar be left for a long time in the direction of the magnetic axis, so as to acquire some oxygenation, or if it be heated to a red heat and suddenly cooled by immersion in water, it will acquire a coercive force, and become permanently magnetic. Iron crosses, weathercocks, &c., which have been long kept in a fixed position, or have been struck by lightning, acquire magnetic properties in the manner above described.

It is a remarkable circumstance connected with the change of molecular disposition caused by the action of heat, that, if we gradually heat a bar of iron, the intensity of its action on a magnet increases, and arrives at a maximum when the bar is brought to a cherry-red heat; with higher degrees of heat the intensity is diminished, and is totally inappre-

ciable when the bar has reached a bright white heat; on cooling, it recovers its powers of action by similar steps, and the same law holds true if the magnet be heated instead of the bar. Hence, in producing the greatest development of magnetism by influence, we see the advantage of using iron or steel bars at a red heat.

Cavallo, Bennett, and Coulomb remarked the indications of magnetism given by various substances, as copper, silver, &c. Coulomb formed very fine needles of various substances, and, suspending them by silk strings between the opposite poles of two powerful loadstones, found that they were acted on by the latter. This phenomenon was formerly attributed to the existence of minute quantities of iron or iron compounds in those different bodies, but this is now known to be a mistake. Faraday has shown that nearly all substances, even gases, have properties in relation to magnetism; and as regards the phenomena which they exhibit, they are divided into two bodies, *paramagnetics* and *diamagnetics*. To the former class belong iron, nickel, cobalt, manganese, crown glass, and platinum; to the latter, bismuth, phosphorus, antimony, heavy glass, zinc, tin, flint glass, mercury, water, lead, silver, copper, gold, alcohol, ether, and arsenic. The term *magnetic* is often used as synonymous with *paramagnetic*. The distinction between the two classes is, that a needle or bar of paramagnetic material, when suspended freely between the two poles of an electro-magnet, takes an *axial* position, that is to say, disposes itself in a straight line joining the two poles; whereas a bar of diamagnetic material takes an *equatorial* position, that is, a position at right angles to the joining line. Again, a body of the former kind, if brought nearer to one pole than the other, is attracted, while a body of the latter class is, in similar circumstances, repelled. The magnetic properties of crystals depend upon their form as well as upon their material, uniaxial crystals having a tendency to place their optical axes in an axial or in an equatorial position, according as the crystals themselves are (in the geometrical sense) positive or negative.

The earliest method of magnetizing a bar of hard iron or steel was by drawing it throughout its whole extent at right angles over one of the poles of a strong magnet; but the magnetism thus developed is feeble, and apparent only at the extremities of the bars, or in some consecutive points formed by peculiarities in the material of the bar, or in the mode of operation. Du Hamel placed two steel bars of equal length parallel to each other, connecting their corresponding extremities by pieces of soft iron interposed; then, taking two bundles of magnetic bars, he united their poles of contrary name near the middle of one of the steel bars, and, inclining the bundles, made one of them pass towards one extremity of the other bar, the second passing in the contrary direction, and then successively repeated the operation, when both the steel bars became strongly magnetized, but with contrary magnetisms at the corresponding extremities of each.

A fine steel needle may be very strongly magnetized by being placed in the axis of a wire twisted into the form of a helix, the extremities of which are brought in contact with the wires of a powerful galvanic battery. The poles of a bar magnetized to

saturation are near its extremities, within generally a few lines, while the intensity becomes insensible at the distance of a few inches; in a thin bar the intensity may be represented by the difference of the ordinates of two logarithmic curves, the origin of one being at the austral, and of the others at the boreal extremity of the needle. (Plate 2.)

When bodies containing neutral magnetisms are made to rotate rapidly round an axis, the magnetism becomes developed and acts on the needle; thus a plate of copper made to revolve rapidly in a horizontal plane will influence a compass-needle placed over it, and produce in it a rotation in the same direction; on which subject several valuable observations have been made by M. Arago, Sir John Herschel, &c. It has also produced a second mathematical memoir from M. Poisson, in which the mechanical force generated by rotation is introduced into the general equations deduced from his theory of the distribution of magnetism in bodies.

Several Magnetic Observatories have been established in various parts of Europe, Asia, and America, from which many valuable contributions to Terrestrial Magnetism have been obtained.

(For the theory of magnetism as connected with electricity consult Robison's *Course of Lectures*; Biot's *Physique*; Becquerel, *Traité de l'Electricité*; Captain Kater's, and Dr. Faraday's Papers in the *Phil. Trans.*; Sir D. Brewster, article *Magnetism* in 'Encyclopædia Britannica.' For the mathematical theory on this subject—the *Memoirs*, by Poisson; Ampère's *Electro-Dynamic Treatise*; Murphy's *Electricity*, chap. vii.; and for more recent developments, Professor J. D. Forbes' *Dissertation*; and Professor W. Thomson's papers in the *Phil. Mag.* for 1850 and 1851, and in the *Phil. Trans.* for 1851, Part I.)

MAGNETISM, ANIMAL. [ANIMAL MAGNETISM.]

MAGNITUDE. This term is generally used synonymously with quantity, and is sometimes even confounded with number. The distinction between the first two terms is not more marked than this:—He who answers the question 'how much?' describes the quantity, and he who answers 'how great?' describes the magnitude. But since magnitude is generally used in our language as applied to amount of space, we may best describe our own idiom by laying down quantity as the general term, and stating magnitude to mean usually the quantity of space. The term, however, must be considered, in a mathematical point of view, as originating with Euclid (whose word is *μέγεθος*); and it is used by him, not particularly as applied to space, but also to everything which admits of the introduction of the notion of greater or less. In this sense, then, we have many magnitudes (all moral qualities for instance) which are not the object of mathematical reasoning. So necessary is the notion of magnitude to our conception even of things which we cannot measure, that we borrow idioms from subjects within the province of mathematics. Thus we speak of force of mind, and of it being greater in one individual than in another. According to the definition of magnitude, namely, 'that of which greater or less can be predicated, when two of the same kind are compared together,' it follows that we include both mental as well as material objects of conception. But the mathematics inter-

pose the postulate that no such object can be made matter of exact reasoning, unless in cases which admit of the comparison being performed according to some method, the results of which shall be self-evident, and inseparable from our notion of the thing measured. Let A and B be two magnitudes of the same kind; they are then, and then only, the objects of mathematical comparison, when other magnitudes equal to A and B can be found, and added together as often as may be desired; and when, moreover, any collection of As can be compared with a collection of Bs, so as to ascertain which is greater or less than the other. Angles furnish an instance of magnitude, the conception of which is exceedingly vague in the mind of most beginners, but which takes precision and certainty in the course of mathematical study. Magnitudes, thus capable of comparison, are the objects of the doctrine of *Proportion*. That part of geometry which precedes proportion considers only the simple alternative of equal or unequal, modes of inequality being necessarily deferred until after that consideration.

By the magnitude of any bounded space the mathematician means the results of measurement; but the common idiom refers to that which the mathematician calls for distinction *apparent* magnitude. It is correct, in the common meaning of the term, to say, that a man at a little distance from the eye is larger than a remote mountain. In thus judging of objects, the angles which they subtend at the eye furnish the means of comparison. Experience, derived from the combination of sight and touch, teaches us how to make those deductions which are necessary before we can learn the absolute from the apparent magnitude.

It is soon found that an object as it recedes grows smaller, that is, subtends a less angle. It is also seen that the recess is accompanied by a loss of brightness and distinctness. The former is a consequence of the loss of light which takes place in its passage through the air; were it not for this, the same object would be equally bright at all distances; for though the quantity of light which enters the eye is diminished by increase of distance, yet the surface from which the light appears to proceed is diminished in the same proportion. The loss of distinctness is a consequence, first of the loss of light, next of the different proportion in which different colours are lost; the effect of the interposed atmosphere amounting to laying on more or less of the blue colour of the atmosphere over the whole. Our perception of magnitude depends both on the subtended angle and on the distinctness; we learn from experience that, of two objects seen under the same angle, the less distinct, as being the more distant, must be the larger. That habit is our guide can readily be shown by producing instances in which we are deceived, the object being either such as is not commonly seen, or seen under unusual circumstances. A colossal statue mounted on a column does not suggest the idea of a man of unusual size to persons in general, unless when some person mounts the same height and affords means of comparison. In a fog, which diminishes the distinctness of objects, but does not affect the angles under which they are seen, these objects are sensibly increased in apparent size, and distant hills appear nearer in a clear day

than in a hazy one. Those who wear spectacles may satisfy themselves by breathing on the glasses, and watching an object as the moisture evaporates, that increase of distinctness gives apparent approximation.

The angle subtended by an object is inversely as its distance, which is sufficiently near for common purposes when angles are small, which is generally the case. And a man of 6 feet high, at a distance of 100 feet, is seen under an angle of $3^{\circ} 26'$. The sun is seen under an angle of $32'$, and the moon under an angle of $29\frac{1}{2}'$ to $33\frac{1}{2}'$.

MAGNOLIA, a genus of plants, the type of the natural order *Magnoliaceæ*. The species of Magnolia are trees or shrubs, all natives of North America and Asia. *M. grandiflora*, Great-flowered Magnolia, or Laurel Bay, is an evergreen tree, reaching sometimes a height of 70 feet. It is one of the tallest and handsomest trees of North America. It has large pale-green shining leaves nearly 10 inches long, with large white flowers. It has been cultivated in England for the last century, and in this country attains a height of from 20 to 30 feet. *M. glauca*, deciduous Swamp Magnolia, is a native of North America, in low, moist, swampy ground at a little distance from the sea, from Massachusetts to Florida and Louisiana. The bark has a bitter and aromatic odour resembling sassafras. On this account it has been used in America as a substitute for other aromatic bitter barks, as Cascarella, Canella, &c., and, it is said, with great success. Although not much used in Europe, very favourable reports of its efficacy in chronic rheumatism, ague, and remittent fever have been given. The flowers are of a cream colour and have a sweet scent, which Kalm says may be smelt at a distance of 3 miles. The flowers are followed by red berries, which give the tree a handsome appearance. *M. umbrellata* is a native of North America, in the Carolinas, Georgia, Virginia, and New York. The wood is soft and spongy, and on the mountains of Virginia is called Elmwood. *M. acuminata* is a native of North America, from Pennsylvania to the Carolinas. The fruit is about 3 inches long, and resembles a small cucumber, whence in America it is called Cucumber-tree. A tincture is made of the fruit, and is used in cases of rheumatism. *M. Yulan*, or *conspicua*, grows in China, where it has been cultivated since the year 627. Its native name is Yulan. It is a very showy tree, having white flowers sometimes diffused with purple, which give out a most delicious perfume. *M. purpurea*, the Purple-flowered Magnolia, is a native of Japan, and seldom attains a greater height than 10 feet. The bark when bruised has an aromatic odour. The flowers are more or less purple without, and always white within. It is a very ornamental species, and worthy of cultivation. The best situation for it is against a wall, when its branches will reach a height of from 15 to 20 feet.

MAGNOLIACEÆ, an important natural order of albuminous polypetalous Exogens, consisting of bushes and trees, inhabiting the temperate parts of both the Old and New World. In England, where they are exotics, they are among the most highly valued of ornamental plants, and every species which can bear the climate, or which will thrive in conservatories, has been collected with great care.

The genera *Talauma* and *Magnolia* have the singular property of dropping their seeds out of the back of the seed-vessels when ripe, allowing them to hang down, each suspended by a long extensible elastic cord, composed of delicate spiral vessels.

In consequence of the seeds of *Magnoliaceæ* containing an abundance of oil, which often becomes rancid soon after they are gathered, it is difficult to transport them to a considerable distance in a living state. The best method of succeeding in that object is to pack the seeds in earth as soon as they are ripe, pressing them close and securing them in a box. Under such circumstances they will preserve their vitality for several months.

MAGOPHONIA (Gr. *Μάγων Φόνος*, 'slaughter of the Magi'), the name of an important festival among the Persians, held in commemoration of the expulsion of the Magi, as mentioned by Herodotus, Strabo, and other ancient writers. It arose from the following circumstances. On the death of Cambyses, the throne of Persia had been occupied by one of the Magi, named Smerdis; when seven of the principal nobles conspired to overthrow him. They were successful; the usurper was killed, and the people rose and massacred all the Magi that could be found. Darius, son of Hystaspes, was then elected king. In commemoration of this event, the grand festival of the Magophonia was instituted, and celebrated for ages. On this day the Magi were not allowed to appear in public; and the people were at liberty to slay them wherever they were met with.

MAGPIE. [CORVIDÆ.]

MAHABHARATA, or BHARATA ('belonging to Bhârata and his descendants'), the most celebrated epic poem of the Hindus after the 'Râmâyan'a.' A passage in the introductory part of the work (1, 2296) has given ground for the assertion that it contains the round number of a hundred thousand distichs or sloçâs; but in order to complete this enormous amount, the 'Harivansa,' a mythological history of Krishna, and sundry other pieces, have been added. The eighteen component fictions (Parva) of the 'Mahâbhârata' contain about 85,000 sloçâs, and even these may be reduced to 24,000 distichs, of which the original 'Bhârata,' without its episodes, is said to have formerly consisted. (1, 101.) The principal subject of the 'Mahâbhârata,' to which its middle sections particularly are consecrated, is a long civil war between two dynasties of ancient India, the Kurus and Pândus.

In this main texture of the 'Mahâbhârata' is interwoven a great variety of episodes; or more properly speaking, the history of the Pândus and Kurus is the leading thread by which many ancient traditions, moral reflections, poetical descriptions, and popular stories of every kind, have been connected. It is important to observe that these accessory elements, which now form almost three-fourths of the whole epopee, are stated in the poem itself not to be constituent parts of the original 'Bhârata;' in fact, they are for the most part very loosely inserted; and as many of them are epic productions of considerable length, the principal theme is not only frequently interrupted by intervening episodes, but often totally lost sight of, even when the most active progression should be expected.

Compared with the 'Râmâyan'a,' the 'Mahâbhâ-

rata' is wanting in unity and internal coherence; it is rather a collection of ancient epic poems, gathered round the central history of the Kurus and Pândus; but for this reason it surpasses the former poem by a greater variety of pleasing scenes and attractive situations, particularly in its episodes, the characters of which are very often delineated with so peculiar a delicacy, and with so strongly marked an individuality, as to leave a powerful impression on the reader. Finally, the 'Mahâbhârata' may be looked upon as a most ample source of every kind of antiquarian lore, and as the only Sanscrit work, if we except the 'Annals of Kashmir,' by which a considerable quantity of the most valuable historical fragments has been preserved. The poem is evidently of later date than the 'Râmâyan'a,' but neither the precise time in which it was composed, nor even the epoch of its finally assuming its present shape, can yet be ascertained.

A complete edition in the original Sanscrit, carefully collated by learned Pundits with the best manuscripts in the library of the Sanscrit College of Calcutta, has been published by the Asiatic Society of Bengal in five quarto volumes. Various fragments and stories of the 'Mahâbhârata' have been translated into English; and several episodes have been published separately. An analysis of the leading story is given by Professor Monier Williams in his *Indian Epic Poetry* (London, 1863). See also Professor Max Müller's *History of Sanscrit Literature*.

MAHMUD I. was raised to the throne of the Ottomans in 1730. He continued the war begun under his predecessor Ahmed against Nadir Shah of Persia, but with no success, and made peace in 1736. He was more successful against Austria, from which he recovered Belgrade; and Russia, which gave up Oczakow. In a new war with Persia, commenced in 1747, he was unfortunate; but he took little part in these transactions, which were managed by his favourites. He died in September, 1754.

MAHMUD II., Sultan of Turkey, the younger son of Abdu-l-Hamid, or Ahmed IV., was born on the 14th of Ramazân, A.H. 1199 (July 20, 1785). The murder of Selim, his uncle, while attempting to regain the throne of which he had been deprived, and the deposition of Mustafa, who had occupied his place, led to the elevation of Mahmud, July 28, 1808. In spite of the threatening state of the empire, Mahmud boldly proclaimed that he would carry out the reforms of Selim. Several pashas were severely punished for disobedience; but when the turn of the janizaries came, they broke out into open rebellion. Mustafa was proclaimed sultan, and the rebels cried out for the head of Mahmud. Mahmud then ordered his captive brother, Mustafa, to be strangled together with his infant son; and those of Mustafa's women and concubines who were pregnant, four in number, were sewn up in leather sacks, and drowned in the Bosphorus. By these murders Mahmud became the only male descendant of Osman, which was a matter of great importance, the popular belief being that Turkey would last no longer than the family by whose great ancestor the empire was founded.

Mahmud succeeded in crushing this bloody rebellion after a struggle of two days, and having conciliated the janizaries, he turned his attention to his relations with the European powers. He made peace

with Russia at Bucharest, May 28, 1812, on conditions more favourable to him than the unfortunate turn of the war allowed him to expect.

Mahmud availed himself of the peace to continue the work of reform. But his success against Ali Pacha, and other rebellious chiefs, was followed by fresh difficulties. No sooner was Ali's head exposed on the gate of the seraglio, than Mahmud had to prepare for a contest with Russia, and an open rebellion of the Greeks. The defeat of the Turko-Egyptian fleet at Navarino by the combined British, French, and Russian fleets, freed Greece from her invaders. None of his defeats dispirited the sultan, and he boldly proclaimed 'a holy war' against Russia. In the meantime, however, events had taken place which led to the destruction of his formidable enemies the janizaries. The sultan, who had for some time resolved upon their destruction, had excited their anger by his reforms and continual adoption of European customs, and an open rebellion was the consequence. On the 15th of June, 1826, while the sultan and the grand vizir were in the country, the janizaries marched in order of battle to the palace of the grand vizir, which they took and burnt down, and they were preparing to attack the seraglio when Mahmud returned, and having nearly the whole population of Constantinople on his side, the janizaries were driven for shelter within their barracks, the Et-Meidân. Their resistance, however, only delayed their fate for a few hours; 6000 janizaries perished in the course of one day; several hundreds, who had not taken part in the action, but were known as rebels, were massacred in the streets or in their houses, and 15,000, who had kept quiet, were exiled to different places in Asia Minor. On the following day, June 16, a hattî sherîf pronounced the abolition of the military corporation of the janizaries. The Russian war which followed proved unfortunate for the sultan, and the empire would have fallen a prey to the Russians, but for the interference of the great European powers, headed by England, through whose mediation the war was concluded by the peace of Adrianople, September 14, 1829. His next war was with Mehemed Ali, in which his pride was still further humbled. The ruin of the sultan seemed to be inevitable. He was saved by his greatest enemy: a Russian fleet and a Russian army stopped the progress of Ibrahim Pasha, the son of Mehemed Ali, who was advancing through Syria to Constantinople. On May 4, 1833, peace was concluded at Koniah, and Mehemed Ali obtained the object of his armament, the investiture of Syria and Adâna, but he remained a tributary vassal of the Porte. So much was Turkey weakened through this war, that Mahmud, despairing of further independence, threw himself into the arms of Russia, and on July 8 signed the treaty of Unkiar-Skelessi, by which Russia bound herself to assist Turkey with an army whenever she should want it, in acknowledgment of which Mahmud promised that no armed ship of foreign nations should be allowed to pass the Dardanelles without the permission of Russia. The remainder of the sultan's reign was occupied by wars against Mehemed Ali, who obtained still further advantages. The sultan died July 1, 1839, a few days before the news of the battle of Nisibis, in which Ibrahim Pasha won a decisive victory over the Turks.

MAHOG'ANY, a beautiful species of cabinet wood, so called from *Mahogani*, the American name of the tree, which is the *Cedrus Mahogani* of Miller, and the *Swietenia Mahogani* of Candolle. It is a native chiefly of the Bay of Honduras, whence it is largely exported to this country. It is also exported from Cuba, Jamaica, Hispaniola, and South America generally. The tree is straight and tall in its growth. It is about 4 feet in diameter, and sometimes rises 60 feet from the spur to the limb. Its foliage is of a beautiful deep green; the flower of a reddish or saffron colour; and the fruit as large as a turkey's egg. Some of these trees grow to a height of 100 feet. The wood is usually hard, takes a fine polish, and is much used in all kinds of cabinet work. The first appropriation of this valuable wood in England possesses some historical interest. At the latter end of the last century, an eminent physician, Dr. Gibbons, had a brother, a West Indian captain, who brought over some planks of this wood as ballast. The doctor being then engaged in building a house in King Street, Covent Garden, his brother thought they might be of service to him; but the wood being found too hard for the carpenters' tools, it was laid aside as useless. Soon afterwards, Mrs. Gibbons wanting a candlebox, the doctor called on his cabinet-maker, Woollaston, in Long Acre, to make him one of some wood that lay in his garden. Woollaston also complained that it was too hard. The doctor said he must get stronger tools. The candle-box was made, and approved; inasmuch that the doctor then insisted on having a bureau made of the same wood, which was accordingly done; when the fine colour and polish were so pleasing, that he invited all his friends to come and see it; among them the duchess of Buckingham. Her grace begged some of the wood of Dr. Gibbons, and employed Woollaston to make her a bureau also, and this contributed to the fame of mahogany, which soon came into general use.

The following were the imports of mahogany into the United Kingdom in 1864:—

	Tons.	Value. £	Average price per Ton.		
			£	s.	d.

MAHOMET. [MOHAMMED.]

MAHOMET I. was the restorer of the Ottoman empire, which he found in a state of anarchy. He extended his conquests into Europe, and obliged the princes of Bosnia, Servia, and Wallachia to pay him tribute. He died, after nine years' reign, in 1421.

MAHOMET II., son of Mourad II., was proclaimed emperor of the Ottomans after the voluntary abdication of his father in 1444; Mourad, however, was obliged to resume the reins of government till his death, in 1451, when Mahomet commenced his reign. He prosecuted many successful wars in Europe, taking Constantinople, Corinth, and

Negropont by storm; he, however, met with some reverses at Belgrade and Rhodes. He died in Bithynia in 1481. His epitaph runs thus:—'I designed to conquer Rhodes and subdue proud Italy.'

MAHRATTAS, or MAHARATTAS. The origin of these people, whose wars have filled so large a space in the history of British India, is involved in much obscurity. The Mahratta empire, as it takes a place in modern history, was founded in the latter half of the seventeenth century, in the reign of Aurangzebe, by Sevaji, a Hindu in the service of the king of Bejapûr, who gave him a jaghire in the Carnatic, with the command of 10,000 cavalry. His first act was to supplant his father Shahjee, in 1647, in the jaghire of Poona; on which occasion he increased the number of his soldiers, and levied contributions in all the neighbouring districts. Sevaji died in 1680, and was succeeded by his son Sambaji, who was unable to withstand the power of Aurangzebe, and, falling into his hands, was put to death in 1689. On the death of Sambaji, a great number of chiefs, availing themselves of the natural facilities offered by the country, issued from various points in the mountains, and kept up a constant predatory warfare in the neighbouring provinces, plundering and devastating wherever they penetrated, till they had become, at the death of Aurangzebe in 1707, more powerful than ever. From the death of Sambaji in 1689 till the year 1818, the nominal sovereign or rajah of the Mahrattas had no real power, but was a prisoner, confined in the hill-fortress of Satara, while the government was administered by the peishwa, or minister, whose office became hereditary in the family of Balaji Baiswanath, its first possessor, who fixed his residence at Poona. He was succeeded by his son Balaji Bajerao, who died in 1761.

The next peishwa was Madhoo Rao, who filled the office for eleven years, and after his death was succeeded by his son Narrain Rao. This chief was murdered in 1773. Ragoba, the uncle of Narrain Rao, claimed the right of succession in opposition to Sevaji Madhoo Rao, who was set up by Nana Furnavese as the posthumous son of Narrain, and who administered the government during his minority. Ragoba fled to Guzerat, where he obtained the promise of support from the Guicowar. For some time preceding these events the English government had desired the possession of Salsette and Bassein, then forming part of the possessions of the Mahratta government. They formed a treaty with Ragoba, engaging to replace him in his office, and they obtained possession of Salsette and Bassein. An English force of 25,000 men was then put in motion in his favour; but negotiations had at the same time been opened with the authorities at Poona, and as they confirmed to the English government the possession of Salsette and Bassein, all active assistance was withdrawn from Ragoba, who retired to Surat with only 200 attendants. Sevaji Madhoo Rao died in consequence of an accidental fall in 1795, and his son Bajerao was declared peishwa. This chief continued in power until October, 1802, when, his forces being totally defeated near Poona by Jeswant Rao Holcar, he fled to Bassein, and placed himself under the

protection of the British government. In the following year he was reinstated in his capital by the duke of Wellington. In 1815 Bajerao was detected in the endeavour to form a general confederacy against the English; his capital was in consequence surrounded, and he was forced to cede in perpetuity districts yielding a revenue of 340,000*l.* In November, 1817, the peishwa, in defiance of his engagements, suddenly attacked and destroyed the houses of the British residency near Poona. This treacherous conduct was speedily punished, his forces were on the following day routed by the English troops, and he became a fugitive, and wandered about in various directions until June, 1818, when he surrendered himself to Sir John Malcolm, and renounced all sovereignty for himself and his family, upon the promise of an adequate pension. On this occasion the greater part of the Poona territory, estimated at 50,000 square miles, came into possession of the English. Though small in stature, the Mahrattas are noted for their courage. They are, however, cruel and perfidious, and have always exercised a most disastrous influence on the people subject to them. No distinction of caste exists amongst them, although they are devout worshippers of Brahma. [HOLKAR; SINDIA; POONA.]

MAI, CARDINAL ANGELO, chief librarian of the Vatican, and a member of many of the learned institutions of Europe, was born at Schilpario, in the diocese of Bergamo, in 1782. In 1812, having risen to some eminence in the literary world, especially for his critical knowledge in palæography, he was appointed keeper of the Ambrosian library at Milan. He soon distinguished himself in the walks of classical and antiquarian lore. In 1814 the first-fruits of his valuable discoveries from palimpsest manuscripts made their appearance. Among others came out the orations of Cicero on behalf of Scæurus, Tullius, and Flaccus, which had been found in the convent of Bobbio, but written over by a poet of the eighth century, named Sedulius; likewise inedited fragments of three other orations, 'in Clodium et Curionem, de ære alieno Milonis, et de Rege Alexandrino.' A second edition of these works appeared in 1817. Abbate Mai now followed up his learned researches with great assiduity, and the results have been laid before the world. A few of his edited works, derived from the same source as the preceding, may here be mentioned:—The works of M. Cornelius Fronto; the orations of Q. Aurelius Symmachus; fragments of six comedies of Plautus, found written beneath a Latin translation of the Old Testament; 'Philo Judæus de Virtute et ejus Partibus' (1816); 'Porphyrî Philosophi ad Marcellum'; 'Sibyllæ libri xiv., the Itinerarium Alexandri' (1817); a volume of Scholiasts of the fourth century upon Virgil, discovered under the works of Gregory the Great (1818); 'M. Tullii Ciceronis de Republicâ, quæ supersunt' (1722), considered as the most valuable discovery made by Mai; 'Scriptorum veterum nova Collectio, è Vaticanis codicibus edita' (1825). The whole of his labours were subsequently printed in two collections, one consisting of ten vols. 8vo, and embracing classical literature, and the other of ten vols. 4to, comprehending the early Christian writers. In 1837 our learned collector was created a cardinal; and subsequently, on the death of Cardinal Lambou-

schini, he succeeded to the post of chief librarian of the Vatican. He died in 1854; but he had directed by his will that his vast library should be offered to the Pontifical government for half its estimated value (8000*l.*), and that the proceeds should be applied to the use of the poor in his native village of Schilpario. The pope, however, succeeded in obtaining the library for 10,000 scudi, or about one-fourth the price originally proposed; and this valuable collection now occupies the Borgia rooms of the Vatican.

MAIANO, BENEDETTO DA, a sculptor and architect, was born at Florence in 1444. He first distinguished himself as a carver and inlayer of wood. His works in marble consisted of fonts, pulpits, and tombs. One of his masterpieces is the marble pulpit of Santa Croce. In architecture he did little, but he built the portico of the church of the Madonna delle Grazie near Arezzo; a chapel for himself on his own estate near Prato; and he is said to have designed the Palazzo Strozzi. He died in 1498.

MAIDEN. The name of an instrument of capital punishment formerly used at Halifax in Yorkshire, and in Scotland. It was the prototype of the French guillotine, and consisted of a loaded piece of iron with a sharp edge, which moved in grooves in a frame 10 feet high. This piece being raised to the top of the frame and let loose, descended and severed the criminal's head from his body.

MAIDEN HAIR. [ADAMTUM.]

MAIDENHEAD. [BERKSHIRE.]

MAIDSTONE. [KENT.]

MA'ID/E, or MAIANS, a group of brachyurous crustaceans (Crabs), constituting the second tribe of the family of the *Oxyrhynchii*, according to the system of M. Milne-Edwards. The genera are numerous.

MAIL (from the French *maille*), strictly 'the mesh of a net,' but applied in a collective view to defensive armour formed of iron rings or round meshes. Boyer, in his French dictionary, translates *maille* 'a little iron ring.'

MAIL, COAT OF (also denominated the Hauberk or Habergeon), armour for the body, of which there were two kinds, one called chain-mail, the other plate-mail. [ARMOUR.]

MAILS AND DUTIES, in Scotch law, are the rents of an estate, whether in money or in grain.

MAIM ('mayhem') is an injury done to the body of a man by forcibly depriving him of the use of some member serviceable in fight, as a means either of defence or offence, and permanently disabling him from offering such an effectual resistance to further attacks upon his person as he otherwise might have done. The destruction of a jaw-tooth, of an ear, or of the nose, or of other members, the loss of which does not interfere with the means of defence or of offence, does not amount to mayhem. But the distinction is by statutory alterations rendered of little importance.

Mayhem was formerly punished by inflicting the same privation upon the offender which he had caused to the party maimed. It was afterwards punishable by fine and imprisonment, as an aggravated trespass. But now, by 24 and 25 Vic. c. 100, whoever shall unlawfully and maliciously wound or inflict any grievous bodily harm upon any other person, either with or without any weapon or instru-

ment, shall be guilty of misdemeanor, and liable to be kept in penal servitude for three years, or imprisoned for two years, with or without hard labour; and if any person hurt or wound with intent to maim, he shall be liable to penal servitude for life, or imprisonment for two years.

Concurrently with these proceedings in the name of the Crown, the party injured is entitled to compensation in the shape of damages, to be recovered in an action of trespass; and where the damages found by the jury are not commensurate to the injury sustained, the court may increase them upon inspection of the mayhem.

MAIMBOURG, LOUIS, born in France in 1620, entered the order of Jesuits, and studied theology at Rome. On his return to France, he was employed as a preacher. Having published, in 1682, a work in which he defended the principles of the Gallican Church, '*Traité Historique de l'Eglise de Rome*,' the Pope caused him to be expelled from the order of Jesuits. Louis XIV. on this occasion gave him a pension, and he retired to the abbey of St. Victor at Paris, where he died in 1686. He wrote also several other works, among which are—a '*History of the Pontificate of St. Gregory*,' and histories of Calvinism, Arianism, and Lutheranism.

MAIMONIDES, or more properly MOSES BEN MAIMON, one of the most celebrated of the Jewish Rabbis, was born at Cordova in Spain, about 1131 or 1133.

The most valuable of his writings are—'*Moreh Nevochim*,' or 'Teacher of the Perplexed,' originally written in Arabic, translated into Hebrew by his disciple Samuel Aben Tybbon, and into Latin by Justinian, bishop of Nebio, Paris, 1520, and by the younger Buxtorf, Basle, 1629, with a preface, which contains an account of the life of Maimonides; and '*Yad Hazakah*,' or 'The Strong Hand,' which contains a complete digest of the Hebrew laws. It is written in remarkably good Hebrew.

Maimonides founded a college at Alexandria for the instruction of his countrymen, in which he delivered lectures on philosophy and the Jewish laws. He died in Egypt at the age of seventy.

MAIN. [BAVARIA.]

MAINA, the modern name of a district of the Peloponnesus, which occupies the south-west part of the ancient Laconica, extending along the range of the Taygetus to Cape Matapan. The inhabitants of this mountainous district were never subjugated by the Turks, but lived in a kind of savage independence, often making incursions into and plundering the neighbouring districts occupied by the Turks, and some of them were pirates. They are now subjects of the kingdom of Greece.

MAINE, LE, one of the old provinces of France, was bounded N. by Normandie, E. by Orléanais, S. by Anjou or Touraine, and W. by Bretagne. It now forms the greater part of the departments MAYENNE and SARTHE, and part of ORNE.

MAINE is the most northern of the United States of North America. It is bounded S.W. and W. by New Hampshire, S. by the Atlantic Ocean, E. by New Brunswick, and N. and N.W. by Canada. The southern boundary of Canada, which had long been in dispute between the United States and Great Britain, was definitively settled in 1846, and is

described in the article **BRITISH AMERICA**. Maine extends from $43^{\circ} 5'$ to $47^{\circ} 20'$ N. lat., and $66^{\circ} 50'$ to $70^{\circ} 55'$ W. long. The area is 31,766 square miles. The population in 1860 was 628,276, of whom 1327 were free coloured, and none were slaves.

Surface and Soil.—The coast-line of Maine is indented by numerous bays, of which the principal are—Casco Bay, Penobscot Bay, Frenchman's Bay, Machias Bay, and Passamaquoddy Bay. These bays contain a great number of small islands, about 400 altogether, and some of considerable size; such as Mount Desert, in Frenchman's Bay, and Long Island, Fox Island, and Deer Island, in Penobscot Bay. Though the frost along this shore is very intense in winter, and the numerous islands favour the formation of ice, the harbours are commonly open all the year round, the strength of the tide, which rises from between 24 to 40 feet, preventing their being closed up. Indeed Maine has more good harbours than any other state in the Union. The country rises gradually, but rather rapidly, from the shore. The surface of the state is mostly hilly; but it is only in the north-western and northern districts that the hills rise to the height of mountains, of which the highest, Mount Kathadino, rises to more than 5385 feet. This mountainous district occupies more than one-fifth of the area of the state.

The centre of the state is occupied by a hilly region, which is well drained by numerous rivers with a rapid course. The southern portion is level and marshy. Along the sea-coast, and from 10 to 20 miles inland, the soil is of moderate fertility, and frequently intersected with sandy and sterile tracts; but beyond this region the soil improves, and produces plentiful crops of grain, flax, and hemp.

Rivers.—The rivers in the southern district have a short course. The principal are the Piscataqua, the Saco, and the Presumpscot, or Casco. East of Casco Bay is a deep indentation which receives two considerable rivers, the Androscoggin and the Kennebec. The Androscoggin rises about $45^{\circ} 12'$ N. lat., $71^{\circ} 15'$ W. long., and flowing S. and W., and again S. and W., after a course of about 200 miles joins the Kennebec near its mouth in Kennebec Bay. The Kennebec rises in several branches on the eastern declivity of the mountain-range which separates Maine from Canada: these branches unite in Moose-Head Lake, a sheet of water about 30 miles long from north to south, with a breadth varying from 5 to 20 miles. From this lake the Kennebec issues in a large stream, and the general direction of the remainder of its course is to the south, till it reaches the mouth of the Androscoggin, after a course of about 250 miles. Though its course is obstructed by falls and shoals, like that of the Androscoggin, it is of great importance in the transportation of lumber. The tide ascends to Augusta, 70 miles from the open sea. The Penobscot falls into Penobscot Bay, has a course of about 250 miles, and is navigable for large ships to Bangor, 52 miles from the sea. The St. Croix, or Scodie, which separates Maine from New Brunswick, enters Passamaquoddy Bay after a course of about 100 miles. Lakes and ponds in the interior are very numerous, especially in the north.

Climate.—The winter is very severe. From the 1st of November to the 1st of April the ground is covered with snow, and the rivers and lakes with ice.

The summer on the sea-shore is very hot; the thermometer frequently rises to 90° , and even 96° , and the weather is subject to sudden and great changes. Drought is frequent, but the country generally is healthy.

Productions, &c.—The principal products of this state are maize, wheat, barley, rye, and flax, with pine and other timber; apples, cherries, &c. The minerals comprise marble, iron ore, and lead. The annual value of the cotton manufactures has been estimated at 2,500,000 dollars. Shipbuilding is also extensively carried on—one-third of all the ships of America being built on the rivers and harbours of this state.

Maine has some good canals, and there are about 600 miles of railway open in the state. There are two colleges, with an aggregate of over 200 students, and 43,000 volumes in their libraries, besides ninety-two chartered academies and 6627 national schools, with an average attendance of 91,519 pupils. It has a state prison, and insane, blind, and deaf-mute asylums.

Towns.—Maine is divided into thirteen counties. The following are the principal towns, with the population of each in 1860:—*Augusta*, situated on both sides of the Kennebec, 43 miles from the sea, at the head of the sloop navigation, is the capital of the state. The two parts of the town are connected by a bridge 520 feet long. The state-house is of white granite, and there are several other handsome buildings, including an arsenal and hospital. Population, 7609. *Bangor* is situated on the west side of the river Penobscot, 60 miles from the sea, at the head of the navigation. The Kenduskeag, a stream 190 yards wide at its mouth, divides the city into two parts, which are connected by bridges. The harbour is spacious, and the tide rises 17 feet in it. Close to the city a bridge of 1300 feet in length crosses the Penobscot. There is a great trade in timber, which employs about 2000 vessels. In the town are a theological seminary, and several schools. Steamboats ply daily to and from Portland and Boston. Population, 16,407. *Bath*, on the west bank of the Kennebec, 12 miles from the sea, is one of the chief commercial towns of Maine. Shipbuilding is largely carried on, and there is an active coasting trade by sailing vessels and steamers. Population, 8076. *Belfast*, a port of entry, at the head of Belfast Bay, on the west side of the river Penobscot, 30 miles from the sea, has a spacious and safe harbour, and a large coasting trade in fish and timber. Shipbuilding is also extensively carried on here. Population, 5500. *Bristol*, a sea-port at the head of Bristol Bay, on the Atlantic, in the place where the first settlement of Maine was commenced, in 1625, has many vessels employed in the coasting trade and fisheries. Population, 4000. *Brunswick*, on the south side of the Androscoggin, contains Bowdoin College, which has a medical school, various museums, and an extensive library. Much lumber is brought down the Androscoggin, and there is great water-power here, by which thirteen saw-mills are driven. Population, 4976. *Calais*, on the river St. Croix. The tide here rises 20 feet, and vessels of the largest class ascend to the lower village, which is connected by a railway with the upper village, 2 miles distant. There is a large trade in timber. Population, 4753.

Eastport is situated on Moose Island, in Passamaquoddy Bay, and has a capacious dock. It is the extreme eastern point of the United States, is a garrison town, and has a bridge connecting it with the mainland. Population, 4000. *Freeport*, at the head of Casco Bay, has a small harbour. Population, 2629. *Gardiner* is situated on the west side of the Kennebec. The river Cobbeseconte here enters the Kennebec, with a succession of falls which afford great water-power. Population, 6000. *Hallowell*, on the west side of the Kennebec, has a population of 4769. *Portland*. [PORTLAND.] *Prospect* is situated on the west side of the river Penobscot, at its entrance into Penobscot Bay. Population, 4000. *Saco* is situated on the east side of the river Saco, 6 miles from the mouth, where there is a descent of 42 feet, which affords great water-power. It has numerous mills, and a fine basin below the falls, where vessels take in their cargoes. Population, 5000. *Thomaston*, between Penobscot Bay on the east, and the St. George's River on the west, 5 miles from the ocean, has a large trade in lime. The Maine state prison is situated here, and the prisoners are employed in quarrying and cutting granite for exportation. Population, 3218. *Vassalborough*, on the east bank of the Kennebec, 11 miles N. by E. from Augusta, has great water-power by means of the outlets of two lakes. Population, 4000. *Water-ville*, on the west bank of the Kennebec, at the terminus of a railway 16 miles north of Augusta, has a Baptist college, and many mills and factories. Population, 3965. *Wiscasset*, at the mouth of the river Sheepscot, has a fine harbour, which admits vessels of the largest size, a good trade, and does a good deal of shipbuilding. Population, 3000. *York*, on the north side of York River, 1 mile from the sea, has a harbour which admits vessels of 250 tons' burthen; a lighthouse, and shipping employed in the fisheries. Population, 4000.

Constitution and History.—The governor of the state of Maine is elected annually. The legislature consists of thirty-one senators and 151 representatives, who are elected for one year. It sends two senators and six representatives to Congress.

Maine seems to have been discovered by one of the Cabots in 1497. It was afterwards visited by the French, who called the southern part, west of the Kennebec, Maine, and the eastern part Acadie. The English made some settlements in the southern district about 1635. The first charter was proprietary, and granted in 1639 to Sir Ferdinand Gorges; but in 1652 Maine was united to Massachusetts, under the title of the county of Yorkshire. Massachusetts, in 1819, gave permission to the freemen of Maine to decide the question of a separation, when, the majority of votes being in favour of it, it became an independent state. In its early history it is said that every twentieth settler was killed by the Indians.

MAINE-ET-LOIRE, a department in France, formed out of the old province of Anjou, and named from its two principal rivers, the Maine and the Loire, is bounded N. by the departments of Mayenne and Sarthe, E. by Indre-et-Loire, S. by the departments of Vienne, Deux-Sèvres, and Vendée, and W. by Loire-Inférieure. Its greatest length is 77 miles, its greatest breadth 60 miles. The area is 2750 square miles, and the population 526,012.

Surface.—The department presents a pleasing variety of low hills, mostly planted with vines, and of plains, which are very fertile. The fields are inclosed by ditches and quickset hedges, within which clumps of trees are planted here and there, the whole giving a warm and agreeable aspect to the country.

Rivers.—The department belongs entirely to the basin of the Loire, which river crosses it from E. to W., and forms in its course several beautiful islands. The northern districts are drained by the Mayenne and its feeder the Oudon, by the Sarthe and its feeder the Loir, and by the Authion. [MAYENNE; SARTHE; LOIRE-ET-CHER; INDRE-ET-LOIRE.] The Mayenne and the Sarthe unite above Angers, and form the *Maine*, which after a course of about 5 miles falls into the Loire S. by W. of Angers. These last-named rivers are navigable; the Loire steamers between Nantes and Tours ply up the Maine as far as Angers. The chief feeders of the Loire from the left bank in this department are the Thouet and the Layon. The Sèvre-Nantaise, and its tributary the Moine, drain a small portion of the south-west of the department. The department is traversed by the Orléans-Nantes Railroad. The climate is healthy, and the temperature mild; winter is rainy; west and south-west winds prevail.

Soil, Products, &c.—The soil is generally fertile, yielding corn more than enough for the consumption. The chief crops are wheat, rye, barley, and pulse of all kinds. Other valuable products are hemp, flax, nuts, excellent fruits, &c. About 11,000,000 gallons of white and red wine are made annually, some of which is of good quality. A considerable quantity of effervescing wine, resembling the true champagne and rivaling it in quality, is manufactured. The department is famous for its melons. A considerable quantity of cider is also made. The forests, which are extensive, consist chiefly of oak and beech. The pasturage is good, and great numbers of horses, mules, horned cattle, and sheep are reared. Deer and wild boars are met with in the forests; wolves and badgers are sometimes seen; foxes, weasels, and wild cats are more common. Feathered game is very abundant. Fish is plentiful; the rivers are infested by otters. Among the reptiles are vipers, adders, the common snake, and land-lizards.

The minerals worked comprise slate, granite, marble, and flint. The quarries of the former, especially those of Angers, are vast and frightful excavations, worked right from the surface of the ground. The principal manufactures carried on are linens, challets, gingham, and calicoes. Grain is extensively exported.

Divisions, Chief Towns, &c.—The department is divided into five arrondissements, which, with their subdivisions and population, are as follows:—

Arronds.	Cantons.	Communes.	Pop. in 1861.
Angers, . .	9	89	159,981
Baugé, . .	6	66	78,641
Segré, . .	5	61	63,407
Cholet, . .	7	77	127,926
Saumur, . .	7	83	96,057
Total, .	34	376	526,012

In the arrondissement of Angers the chief town is ANGERS, which is also the capital of the whole department. *Chalennes*, prettily situated at the foot of a hill between the Layon and the Loire, 14 miles S. by W. from Angers, has 6089 inhabitants, who manufacture serge, handkerchiefs, and brandy. *St.-Georges*, W. of Angers, and near the right bank of the Loire, has a population of 2757. *Ponts-de-Cé*, a town of 3739 inhabitants, stands about 4 miles S. from Angers, at the entrance of the Authion into the Loire. It takes its name from the series of bridges that here connect the banks of the Loire with the intervening islands. These bridges form one of the most important passes of the Loire; they are partly of wood and partly of stone, and contain 109 arches in all, the entire length, including the causeway, being 3280 yards. The town consists merely of rows of houses built along the causeways connecting the bridges. About half a mile below Ponts-de-Cé, and on the right bank of the Loire, is an ancient Roman encampment. Six miles S.S.W. of this town, 306 soldiers were drowned while crossing a bridge in April, 1850.

The arrondissement of Baugé is named from its chief town, *Baugé*, which stands E. of Angers, near the Couesnon, a feeder of the Authion, and has a civil tribunal, a college, and 3546 inhabitants, who manufacture coarse woollens, linen, and articles of horn. The old castle built here by Foulques Nera is well preserved, and forms now one of the finest hospitals in Maine. In 1421 the English, under the duke of Clarence, were defeated here. *Beaufort*, situated in an extremely fertile country on the right bank of the Loire, has a communal college, and 5260 inhabitants, who manufacture sailcloth, zinc, leather, &c. There is also a considerable trade in corn, wine, oil, fruit, hemp, &c. *Durtal*, a town of 3528 inhabitants, is built at the foot and on the slope of a hill on the right bank of the Loire, which is here passed by a bridge of cut stone. Earthenware, tiles, bricks, and paper are manufactured here. *Longué*, on the Lathon, a feeder of the Authion, a few miles S. of Baugé, has 4283 inhabitants, who manufacture linen cloth.

The arrondissement of Segré is named from its chief town, *Segré*, which is situated in the north of the department, on the Odon, a feeder of the Mayenne, and has a tribunal of first instance, and 2032 inhabitants. *Lion-d'Angers*, a well built little town, near the junction of the Odon with the Mayenne, has a population of 2745. *Pouancé*, in the north-western angle of the department, has iron-smelting forges and blast furnaces, and 3227 inhabitants.

In the arrondissement of Cholet the chief town, *Cholet*, or *Chollet*, a busy manufacturing place in the south of the department, stands on the Maine, and has a council of Prud'hommes, a college, and 12,735 inhabitants. The town was burnt in the Vendean war by the Vendéans and the Republicans; but it has been since rebuilt. It is famous for the manufacture of linen and pocket-handkerchiefs; the material *chaillet* deriving its name from this town. Flannel, calico, cotton yarn, and leather are also made; there is a brisk trade in these articles, and in cattle and agricultural produce. *Beaupréau* stands on the Erve, a feeder of the Loire, 27 miles S.W. from Angers, and has a college, and 3821

inhabitants. There is a fine turreted château near the town. Leather, flannel and other woollen stuffs, and linen are manufactured. *Chemillé*, E. of Beaupréau, on a river called Ionne, is an old town with 4703 inhabitants, who manufacture linen of all kinds, calico, cotton yarn, and paper. *St.-Florent-le-Vieil*, a town of 2368 inhabitants, stands on a steep hill above the left bank of the Loire.

In the arrondissement of Saumur the chief town, *Saumur*, stands in a charming situation on the left bank of the Loire, at a distance of 40 miles by railroad W. from Tours, and has 14,079 inhabitants. It has a civil tribunal and a tribunal of commerce, a communal college with a library, a riding school for the army, a theatre, baths, &c. Linens and cambrics are manufactured here, but it lost its industrious Protestant artisans through the revocation of the edict of Nantes by Louis XIV., and has now little more than half the population it possessed two centuries ago. There are several fine promenades; the view from the castle over the valley of the Loire is very splendid. The environs of Saumur, along the left bank of the Loire, abound in druidical monuments. *Doué*, S.W. of Saumur, is a well built little town, with 3337 inhabitants, who trade in corn, linen, iron, and cattle. It possesses one of the finest fountains in France, both in an architectural point of view and on account of the abundance of its waters. *Fontevrauld*, in the south-eastern angle of the department, 9 miles from Saumur, has a population of 3394. The town owes its existence to the famous abbey of Fontevrauld, founded in 1099, of which the great church, a magnificent monument of the twelfth century, and all the other buildings now remaining, have been converted into a central prison. The abbey possesses great interest for an Englishman; it contains the cemetery of the Norman kings of England and the counts of Anjou. The tombs of Henry II. and his queen, Eleanor of Guienne, of Cœur-de-Lion, and Elizabeth, the queen of John, alone have been saved from utter destruction.

The department forms the see of the bishop of Angers, is included in the jurisdiction of the High Court (Cour Impériale) of Angers, the Academy of Rennes, and belongs to the fifteenth Military Division, of which Nantes is head-quarters. The department returns four members to the Chamber of Deputies.

(*Dictionnaire de la France; Annuaire pour l'An 1866*).

MAINIOTES. [MAINA.]

MAINTENANCE is defined to be when a man maintains a suit or quarrel to the disturbance or hindrance of right. If he who maintains another is to have by agreement part of the land or debt, &c., in suit, it is called Champerty. Maintenance was an offence at common law, and has also been the subject of several statutes, one of which is the 32 Henry VIII. c. 9.

MAINTENANCE, SEPARATE. [ALIMONY; DIVORCE.]

MAINTENON. [EURE-ET-LOIR.]

MAINTENON, FRANCOISE D'AUBIGNÉ, MARQUISE DE, was born at Niot, in 1635. She was first married to Scarron, the comic poet. When Scarron died in 1660, his widow was left poor; but some of her friends recommended her to Madame de Montespan, the mistress of Louis XIV., as governess

to her children by the king. She thus became known to Louis, who gradually conceived great esteem for her. The king made her a present of 100,000 livres, with which she purchased the estate of Maintenenon, when the king conferred on her the title of Marquise. Having consulted his confessor, Père La Chaise, the latter advised a private marriage; and in 1685, Louis, who was then forty-seven years of age, was secretly married to Madame de Maintenenon, who was fifty years old, by the archbishop of Paris, in presence of the Père La Chaise and two more witnesses. The marriage was always kept secret, and Madame de Maintenenon herself never avowed it. She exercised great influence over the king. After the death of the king she retired to Saint Cyr, where she died in 1719.

MAINZ, *Mentz*, or *Mayence*, the Roman *Moguntiacum*, the capital of the province of Rheinhessen in the grand-duchy of Hesse-Darmstadt, is situated on the left bank of the Rhine, a little below the junction of the Main with that river, on the slope of a hill, in 50° N. lat., 8° 11' E. long., and had in 1861, 41,279 inhabitants, exclusive of a garrison of 10,000 troops, half Prussian and half Austrian. It is connected, by a bridge of boats and a railway iron bridge over the Rhine, with the village of Kastel, or Kassel, included in its system of fortifications, which render Mainz one of the strongest fortresses in Europe, and a chief bulwark of Germany against France. As a fortress it belongs to the German Confederation, and the military governor, who retains his post five years, is alternately an Austrian or a Prussian general. The town is ill built. The streets are narrow, crooked, and gloomy, though there are many handsome edifices. Of the squares, the principal is the Parade, which is surrounded with avenues of trees. Of the eleven churches, of which one is for Protestants, the most remarkable are the cathedral, a vast building, surmounted by a lofty cupola; the church of St. Ignatius, which is considered a model of beautiful ecclesiastical architecture; St. Peter's; and St. Stephen's. The other chief buildings are the grand-ducal palace, the arsenal, the palaces of the commandant and of the vice-governor, the episcopal palace, the theatre, &c. A bronze statue of Gutenberg (the inventor of printing, and a native of Mainz), modelled by Thorwaldsen, and cast in Paris, was erected in an open space opposite the theatre in 1837; the expenses were paid by subscriptions from all parts of Europe. A literary club now occupies the site of his house. A gymnasium has taken the place of the former university, and there are several schools. The city library consists of above 110,000 volumes, and in the same building there are extensive collections of Roman antiquities, medals, &c. The Eichelstein in the citadel is supposed to be a monument in honour of Drusus Germanicus, brother of the Emperor Tiberius. The environs are very beautiful, and the prospects over the surrounding country magnificent. Mainz is a free port; it has few manufactures, but the commerce is considerable. Steamers ply regularly to the chief towns on the Rhine. Two railroads run from Kassel, one E. to Frankfurt-am-Main, the other N. to Wiesbaden. The town was taken by the French in 1797, but ceded to Hesse-Darmstadt in 1815.

MAINZER, DR. JOSEPH, was born at Trèves in the year 1801. He received a liberal education at the college of his native town, and was afterwards apprenticed to a mining engineer in the coal-fields of Dutweiler and Saltzbach. But he was soon compelled to abandon this career by the utter inadequacy of his physical strength for its arduous labours. From his earliest years he had evinced great musical ability, and an ardent attachment to the science, employing all his leisure hours in its cultivation. He now determined to embrace the musical profession, and placed himself as a pupil under Kinck, the kapelmeister to the grand duke of Darmstadt, who himself had been a pupil of Kittel, the last disciple of Sebastian Bach. When he had exhausted all that Kinck could teach, he repaired to Munich, where he studied under the Chevalier Seyfried, and to Vienna, where his master was the once celebrated Abbé Stadler. At Rome he received lessons from the Abbé Baini, the director of the music of the pontifical chapel. After a course of study which extended over two years, he returned to Trèves, and commenced the development of that new system of musical instruction which is associated with his name, and which had long occupied his thoughts. His system soon became popular, and in 1830 he removed to Paris, where he speedily obtained a liberal and extensive patronage; but the police growing suspicious of his popularity, and connecting it with political designs, compelled him to close his singing-classes. He then occupied himself with private lessons, and in contributing art-papers to the *Revue des Deux Mondes*, the *Revue du Nord*, and other periodicals of reputation. For six years he superintended the musical department of the *National*, and for a considerable period acted as the Paris correspondent of the *Leipzig Musical Gazette*. He removed to England in 1844, and popularized his system in most of the great cities, finally establishing himself at Manchester, where he successfully laboured until 1851. He wrought much good in his generation, but his works are now held in very little esteem.

MAIRE (whence the Mayor of a corporation), among the ancient Franks the title of the supreme magistrate or political head of the state. He was usually elected by the nobles as a set-off against the absolute power of the sovereign, and at length became possessed of all the rights and prerogatives of royalty. Indeed, neither rank nor dignity exempted a Frank from obedience to him. These Maires were actual ministers in peace, and independent generals in war. At length, after a long abuse of exorbitant power, they brought both constituents and masters into subjection. It is related, however, that Clotaire II., king of Western France, after his conquest of Burgundy, prevailed on the nobles of that kingdom, on the death of the Maire Varnacarius, to suppress that dignity in his favour. But under his successor, and irrevocably from the reign of his grandson Clovis II. of France, the royal dignity and that of Maire of the palace became separate offices in the state, each possessing his distinct rights and prerogatives.

MAIRE, JACQUES LE, was born about 1590. He is remembered as the discoverer of the Straits of Le Maire, and the first navigator who doubled Cape Horn: he was incited to the enterprise by the right of the Dutch East India Company to prohibit any vessel not belonging to them to double the Cape of

Good Hope. He died in December, 1616, on his voyage home from Batavia.

MAITLAND, SIR RICHARD, of Lethington, was born in 1496. He studied law in France, and on his return to Scotland followed that profession. In 1550 his book of 'Reports of the Decisions of the Court of Session' commences; and about the same time he appears in the sederunts of the court as an extraordinary lord of session. Sir Richard became blind about the year 1559, about which date he concludes his 'History and Chronicle of the House and Surname of Seaton.' In 1562 he was made lord privy-seal; but this office he in a few years afterwards resigned in favour of his second son John. He died March 20, 1586. His valuable collection of Scottish poetry is now preserved in the Pepysian Library, Magdalen College, Cambridge. His poetical writings have been printed by the Maitland Club.

MAITTAIRE, MICHAEL, was born in France, 1688, of Protestant parents, who settled in England at the revocation of the edict of Nantes. He was educated at Westminster school under Dr. Busby, whence he went to Oxford. From 1695 to 1699 he was second master in Westminster school. In 1699 he resigned that appointment, and devoted the remainder of his life to literary pursuits. He died August 4, 1747, at the age of seventy-nine.

Maittaire was a learned and laborious scholar. He edited many of the classical authors, with useful indexes, and also wrote several works, of which the most important are—'De Græcæ Linguæ Dialectis,' Lond., 1706, 1742, the best edition of which is by Sturz, Leip., 1807; 'Historia Typographorum aliquot Parisiensium, Vitas et Libros complectens,' Lond., 1717; 'Annales Typographici ab Artis Inventæ Origine ad Annum 1557 (cum Appendice ad Annum 1664),' Amst. and Lond., 1719–1741.

MAIXENT, ST. [SÈVRES, DEUX.]

MAIZE, or *Indian Corn*, is a plant commonly cultivated in the warmer parts of the world, where it answers a purpose similar to that of wheat in more northern countries. It is the *Zea Mays* of botanists, a monocœious grass, of vigorous growth, with stems not more than two feet high in some varieties, and reaching the height of eight or even ten feet in others. Each grain has a long thread-like style, which projects beyond the enveloping sheaths; and as there are some hundreds of them upon each spike, the whole form a long tassel, which looks as if made of silk. A plant generally bears two full ears, the grains of which vary greatly in number: some of the largest ears in America contain at least 800 grains.

This plant in its wild state is met with in Paraguay, in Chili, and in North America. The bread made from maize is not so palatable to some as wheat bread; but by mixing it in certain proportions with wheat, it makes a very pleasant food. In the United States of North America, Indian corn forms almost the only bread eaten by many of the people; and in the slave-states it is the only bread that the negroes eat. It is not, however, in the shape of baked bread that maize is most generally used in Europe, but in boiled messes and soups, as peas are with us.

A light, moist, and warm soil suits this plant best. It thrives well on land broken up from grass. The time for sowing maize in the south of France is the month of April; farther north, it is sown later. The

distance between the rows of maize varies from two to four feet. The seed is sometimes sown in the furrow after the plough, and sometimes put in with the dibble. Two or three inches deep is sufficient to make the seed germinate readily. In warm moist climates the plant is very soon above ground. When the plants are three or four inches out of ground, and no frost is feared, they are thinned out to two feet apart, and in very rich soil three feet is better. Maize, however sown, must be repeatedly hoed. At the first hoeing the plants which are too close are pulled up. When the plants are a foot high, there is a second hoeing; and when the flowers are ready to expand, a third hoeing is given, to kill weeds and open the surface of the soil slightly. The young ear is preserved as a pickle, like young cucumbers: when a little advanced, it is roasted on the coals, or before the fire, and is pleasant to eat: in the green state, when the grains are still soft and milky, it is boiled and used as a vegetable, and is considered a delicacy.

When the maize is fully ripe, the ears are twisted off by hand and laid in a dry place; they are turned occasionally, that the sheath may not become musty, and are then stored in a dry place. The leaves are gathered for fodder a short time before the ears are pulled. In America and in Italy mattresses are stuffed with the dry sheath, which makes a cool and elastic bed.

Horses, pigs, and poultry are fond of maize; it gives the flesh of the last two a peculiarly fine flavour. One of its most important uses in Europe is to be cut green as food for cows, oxen, and sheep. In a proper climate there is no plant which gives so great a mass of green food. Its produce is most abundant. The imports in 1865 were 7,000,000 cwts.

MAJESTY. Among the Romans the word *majestas* was at first used to signify the power and dignity of the people, and also of their representative assemblies who derived their power from them. On the establishment of the empire, the appellation became exclusively the attribute of the emperors, and from them it descended to those of Germany, who considered themselves their successors. It is now usually bestowed on all sovereigns, but its adoption is of comparatively recent date. 'Your Grace,' or 'Your Highness,' was the mode of addressing the king, in England, up to the latter part of the reign of Henry VIII., when the term Majesty was first employed. Henry II. was the first king of France so styled. Louis XI. and his successors were granted the title of 'Most Christian Majesty,' by a bull from the pope; and by virtue of the same authority Ferdinand and Isabella of Spain obtained for the sovereigns of that country the title of 'Most Catholic Majesty.' The same power also conferred the title of 'Apostolic Majesty' on Maria Theresa and her successors. The queen of England is personally addressed as 'Your Majesty,' but in writing, as 'The Queen's Most Excellent Majesty.'

MAJOLICA, the name given to a kind of earthenware, first manufactured in the island of Majorca. It was afterwards produced at Faenza, from which it is sometimes known as *Faience ware*. Specimens of the original Majolica and Faience are now comparatively rare, and fetch a high price in the market. They are eagerly bought up by *connoisseurs* in articles of *vertu*. The ware now commonly referred to under

this name, is much used in Italy, and is not of great value.

MAJOR, in Music, a term applicable to the imperfect concords, but chiefly to the interval of the 3rd. It is also used to distinguish the mode which takes a major or sharp 3rd, from that having a minor or flat one. The *major* mode has always a greater 3rd—*i.e.*, a 3rd consisting of two tones; and the *minor* mode has always a minor 3rd—*i.e.*, a 3rd consisting of a tone and a semitone.

MAJOR (Lat. 'greater'), a field-officer next in rank below a lieutenant-colonel, and immediately superior to the captains of troops in a regiment of cavalry, or to the captains of companies in a battalion of infantry. His duty is to superintend the exercises of the regiment or battalion, and on parade or in action to carry into effect the orders of the colonel. The major has also to regulate the distribution of the officers and men for the performance of any particular service. His daily pay in the life-guards is 1*l.* 4*s.* 8*d.*; in the foot-guards, 1*l.* 3*s.*; in cavalry, 19*s.* 8*d.*; infantry, 16*s.* The regulation price of his commission in the cavalry and infantry of the line is 3200*l.* There are no majors in the artillery, engineers, or marines.

A brigade-major is a staff-officer who performs for a brigade, or in a garrison, duties corresponding to those of a major in a regiment or battalion.

A serjeant-major of a regiment is a non-commissioned officer, who in general superintends the military exercises of the soldiers: on parade, he has the care of dressing the line.

MAJOR-GENERAL. [GENERAL.]

MAJORCA. [BALEARIC ISLANDS; SPAIN.]

MAKRIZI, a celebrated Arabic writer, was born at Cairo, between 1358 and 1368. It appears that he resided at Cairo during the greater part, if not the whole of his life, that he discharged at different times the duties of several public offices, and that he died, at an advanced age, in 1442.

Makrizi wrote several historical works, of which the most important is his 'Description of Egypt,' which gives an account of the history of the country from its conquest by the Mohammedans, as well as a description of its natural history and antiquities, and of the manners and customs of the inhabitants.

MALABAR, a maritime district of British India, in the presidency of Madras, between lat. 10° 15' and 12° 18' N.; long. 75° 15' and 76° 55' E. Its boundaries are—W., the Arabian Sea; S., Cochin; E., Mysore and Coimbatore; N., Canara and Coorg. The coast-line abounds in shallow havens, and extends for about 125 miles. The area of the whole district is a little over 6000 square miles, and the population numbers about a million and a half. The shores are generally low, barren, and sandy, but the interior is traversed by the Western Ghats, and in some of the streams descending from them gold dust is found. Iron ore is dug in the hills. So great was the demand for the teak timber with which the mountains are covered, and which is of superior quality for shipbuilding, that the woods were in some danger of being exhausted, and extensive tracts of waste land have been planted by order of the government. The products of the soil are those usually found in eastern latitudes; the climate on the sea-coast is warm and equable; the mean temperature

being about 78° Fahr. Many diseases, chiefly caused by unwholesome food and filthiness, are prevalent; and from the same causes cholera has often been severe. Nearly all the tropical animals, except the lion, are found, and the sea and inlets swarm with fish of excellent quality. The principal places in Malabar are Cochin, Cannanore, Pennani, and Tellicherry. The population consists of Hindoos, Mussulmans, Christians of different denominations, and Jews. The Hindoos are divided into several castes—the Brahmin and the Puttar (both of whom burn their dead); the Nairs and the Tiars, or cultivators of the ground. The Nairs, the second in rank, are a numerous and influential caste of the military class, and always carry with them a naked sword. If touched by a Tiar or a slave, they are considered defiled, and must immediately wash their bodies; but before the establishment of the British rule they at once slew the unfortunate individual who came in contact with them. Malabar was annexed to the British dominions at the downfall of Tipoo Saib, before which slaves were a numerous and degraded class; but slavery is now abolished, and measures taken to provide employment for the emancipated, and education for their children. Fanatical outbreaks are common among the native Mussulman farmers, especially in the interior. They are fierce and bigoted ruffians, but the native traders are a very peaceable class.

MALACCA, a town in Southern Asia, situated on the western coast of the Malay Peninsula, in 2° 14' N. lat. and 102° 12' E. long., on the Straits of Malacca. The remains of Portuguese and Dutch forts still occupy summits around the town, the principal edifices in which are the barracks, court-house, town-house, gaol, civil and military hospitals, and convict prison. Altogether the town is well built and presents an imposing appearance from the sea. It contains the church of our Lady del Monte, the scene of the labours and supposed miracles of St. Francis Xavier, 'the Apostle of the East.' Malacca was first visited by the Portuguese in 1507, and was taken by Alfonso Albuquerque in 1511. It continued in a flourishing condition till 1640, when it was taken from the Portuguese by the Dutch. The British obtained possession of it in 1795, the Dutch in 1801, the British again soon afterwards, the Dutch again in 1814, and the British finally captured it in 1824.

Besides the town, this colony consists of a tract of country about 40 miles long and 30 miles wide. The country lying along the sea-coast, to the distance of 12 or 15 miles, is low and nearly level; in many parts swampy, and mostly covered with wood. The climate is salubrious, the thermometer ranging from 72° to 85° Fahr. The soil near the coast is fertile, but in the interior it is not so, being mainly valuable for its tin mines. The exports comprise gold dust, tin, hides, poultry, pepper, rattans, lace, aloe-wood, ebony, ivory, and Chinese hardware, to the value of about 400,000*l.* annually. Its imports are worth about the same, and consist of British and Indian manufactured goods, opium, rice, salt, &c. The settlement, previously a dependency of the Bengal presidency, was separated therefrom in 1861. In 1860 the inhabitants of the province numbered 80,792.

The bulk of the population consists of Malays. There are some Hindus and Chinese, and also some descendants of the Portuguese and Dutch.

MALACCA, THE STRAITS OF, separate the Malay Peninsula from the island of Sumatra. They begin on the north between Diamond Point on Sumatra, and the island of Pulo Penang, near the shores of the continent, about $5^{\circ} 20'$ N. lat., and terminate on the south between the most southern cape of the Asiatic continent, the Tanjong Burus ($1^{\circ} 15'$ N. lat.), and the islands of Carimon or Krimun (1° N. lat.). Its direction is from north-west to south-east, between $97^{\circ} 30'$ and $103^{\circ} 40'$ E. long. At its northern extremity it is 250 miles wide, but it diminishes to 30 miles near the southern end. Perhaps in no part of the globe is the temperature of the air less subject to changes than on these shores. In the Straits of Malacca, are the British settlements of PENANG, MALACCA, SINGAPORE, generally called the STRAITS SETTLEMENTS, which are all under one governor, whose head-quarters are at Singapore.

MALACHI, the last of the twelve minor prophets. Nothing is known of his life; and indeed, as the name occurs nowhere else as a proper name, and signifies 'messenger,' many conjectures have been ventured as to the real person, some identifying him with Ezra, and some supposing that he was an incarnate angel. It is probable, as the editor of the 'Pictorial Bible' thinks, 'that the prophecy is anonymous,' and that the title Malachi is given to the prophet from the distinct prediction concerning 'my messenger' (iii.1), which has always been considered by both Jews and Christians as one of the most remarkable and important prophecies in Scripture. Its authenticity and canonical authority have never been questioned.

MALACHITE (Gr. *μαλάχη*, 'mountain green'), the native-green carbonate of copper, which is found in a few localities of Siberia and South Australia. It is seldom met with in masses of more than ten or twenty pounds' weight; but in Siberia there is a bed of malachite supposed to weigh half a million pounds, which lies imbedded at a depth of 280 feet in a copper mine. When polished it has all the appearance of a bright and beautiful green marble, intersected and variegated with light-coloured veins. But so little was known of this mineral before the Hyde Park Exhibition of 1851, that the public knew not whether the specimens there exhibited were stone or composition. Of late years, however, a malachite manufactory has been established at St. Petersburg, the material of which is chiefly derived from a mine in Siberia, belonging to MM. Demidoff; and their specimens of large doors, vases, and other articles are very beautiful. The fragments of malachite are first sawn into thin plates, about the tenth of an inch in thickness. The artist has to determine what convolution or pattern the different green-tinted markings will present in the finished article, and he so selects the veneers, or small pieces, as to attain that object. When the pieces have been fixed with cement on some substance, as marble, copper, or iron, the small interstices are filled up with cement mixed with particles of malachite, and coloured with a powder of the same material. After this the grinding and final polishing takes place. The process, however, is very tedious and expensive. The malachite doors, which

excited so much admiration at the Great Exhibition, employed thirty workmen for a whole year. Moreover, the cost of the raw material is very great. The average pieces brought up from the mine are valued at 15s. per lb.; and there is, besides, considerable waste in the working. All these circumstances materially add to the costliness of the articles produced.

MALACOLOGY. The science of *Molluscous* or *Soft-bodied Animals* (*Μαλακὸς*, 'soft,' and *λόγος*, 'a discourse'), includes the knowledge of such animals, whether protected by shells or entirely naked, and their distribution into classes, sub-classes, families, genera, and species. In this more extended and philosophical view of the subject *Conchology* may now be considered as merged; and the more modern classifications are based upon the anatomy of the soft parts and the habits of the animals, as well as upon the structure of the shells in those molluscous forms which have that protection.

The shell collector of former days looked upon his drawers, if they were rich in rare species or varieties, as containing an assemblage of gems; and indeed the enormous prices given for fine and scarce shells, joined with the surpassing beauty of the objects themselves, almost justified the view which the possessor took of his cabinet of treasures. They were to him objects of the greatest delight; and the energetic zeal with which he collected, and the sacrifices that he made to procure a fine and perfect *Many-ribbed Harp*, a *Gloria Maris*, or *Cedo Nulli*, among the cones, an *Aurora* or *Orange-cowry*, a *Voluta aulica* or *Voluta Junonia*, &c., were only comparable to the extravagancies of those visited by the tulip mania when it was at its height. But though they were the delight of his eyes, they were, in nine cases out of ten, little more to the owner of them: they were mere trinkets on which he looked doatingly without knowing, and scarcely wishing to know, the organization of the animal whose *skeleton* only was before him. This innocent trifling came at last to be viewed in its true light by some collectors worthy of better employment, who put off childish things and went deeper into the subject. Lister, Adanson, Linnaeus, Poli, Cuvier, Lamarck, De Blainville, and others, gave dignity to this department of zoology, and gradually raised the science to its proper rank; whilst the comparatively imperishable nature of the covering of the testaceous molluscs became, in the hands of such men as William Smith and his followers, among the most valuable records by which the stratification of the earth's crust could be demonstrated, and its geological history deciphered.

M. de Blainville's term, *Malacozoa*, or *Malacozoaria*, is not generally adopted in this country.

[ANIMAL; CONCHACEA; CONCHIFERA; CONCHOLGY; CEPHALOPODA; GASTEROPODA.]

MALACOPTERYGII, according to Cuvier, the second great division, or order, of Osseous Fishes, the species of which are distinguished by all the rays of the fins being soft and cartilaginous, exhibiting minute articulations, and often divided into small fibres at their extremities. It frequently happens, however, that the anterior ray of the dorsal or of the pectoral fins is hard and bony—a character observable in nearly all the species of the *Silurida*, and in many belonging to other families.

The greater portion of the fishes of this order have

the scales formed of simple laminae, and with smooth margins; in this respect differing from the species of the *Percidae*, *Sciaenidae*, &c., in which the edges of the scales are pectinated or serrated. The *Pleuronectidae* or Flat Fishes, however, present the latter structure of scale, and yet, according to Cuvier, are placed in the *Malacopterygii*. M. Agassiz on this account removes this group to another section, and he also arranges the *Siluridae* in another group, owing to the structure of their scales.

The *Malacopterygii* are divided into three sections. First, the *Abdominales*, in which the ventral fins are situated on the abdomen, far behind the pectorals. In the second section (*Subbrachiales*) the ventral fins are situated immediately beneath the pectorals, and the pelvis is suspended to the bones of the shoulder. In the third section (*Apodes*) the ventrals are wanting.

MALACOSTRACA (Μαλακίστρακα), a term employed by Aristotle to designate the *Crustacea* generally, but confined by Dr. Leach in his arrangement to the second order of the class. The *Malacostroaca* of Leach are divided into three tribes:—1. *Brachyuri*, 2. *Macrouri*, 3. *Gasteruri*.

MALAGA, an episcopal town, seaport and capital of the province of the same name, is situated in 36° 45' N. lat., 4° 30' W. long., on the shore of the Mediterranean, and has 113,000 inhabitants. The Guadamedina, a mere brook in summer, but in winter a stream of considerable volume, enters the sea immediately to the west of the city. Malaga is of great antiquity. It was possessed successively by the Carthaginians, Romans, Goths, and Arabs. In 1487 Ferdinand and Isabella wrested it from the Moors after a siege of three months. Malaga has suffered severely in different epochs from the plague, which on one occasion cut off 20,000 of the inhabitants in forty days, and in 1803–4 the yellow fever decimated the population. It is, however, much resorted to in winter on account of the salubrity of its climate. In fact winter in an English sense is unknown, and it is considered by many to be superior as a resort for invalids, to any place in France or Italy.

From the earliest ages, under all the nations who have possessed it, Malaga has been renowned for its commerce. Its imports are colonial produce, broad cloths, cottons, laces, spices, hardware, and cutlery. Its exports amount to about 1,000,000*l.* sterling annually. They consist of wine, grapes, muscatel raisins, almonds, figs, lemons, olive oil, brandy, anchovies, and lead. Though the streets are narrow, tortuous, ill-paved, and dirty, the city has a gay and cheerful aspect, as the exteriors of the houses are whitewashed or painted yellow. Many of the roofs are flat, as in the East, and are surmounted by square towers with open galleries, where the citizens enjoy the cool sea-breezes. The city has several schools and public hospitals, two large iron-foundries, and a royal cigar factory. Malaga possesses a cathedral, a light and handsome building in the Græco-Gothic style, which is nearly 400 feet long, 180 broad, 125 in height, and is surmounted by a spire 302 feet high. The other public buildings are the bishop's palace, four parish churches, five hospitals, the opera-house, custom-house, legal seminary, and a convict dépôt. The harbour of Malaga is spacious enough to accommodate a large fleet; it is protected on the east by a massy stone mole, five

furlongs in length, and terminated by a handsome lighthouse. The harbour may be entered during any wind. The sea is, however, gradually receding, and the Moorish dockyard and quay are now in the town, while the alameda or public walk was covered with water in the last century. The great boast of Malaga is the Moorish castle, built in 1279, and covering the slope of a hill immediately to the east of the city; it is of great extent, and still shows the effects of the Christian artillery in the siege of 1487.

MALARIA. [MIASMA.]

MALAVILLY, a town of Hindustan, in the province of Mysore, rendered memorable by the victory obtained in 1779, by General (afterwards Lord) Harris, over Sultan Tippee's army.

MA'LAXIS, a genus of plants belonging to the natural order *Orchidaceæ*, and to the tribe *Malacideæ*. Of this genus there is one British representative, *M. paludosa*. It is a small plant, with a stem from one to four inches in height.

MALAY PENINSULA constitutes the most southern extremity of the continent of Asia, extending between the Gulf of Bengal and the Straits of Malacca on the west, and the Gulf of Siam and the Chinese Sea on the east. It is united to the continent at its northern extremity. Its most southern points form the northern shores of the Straits of Singapore. Kwi Point, in the Gulf of Siam, and the mouth of the Tenasserim River, which enters the Gulf of Bengal, may be considered as constituting its northern boundary; they are situated near 12° N. lat. Cape Burus, the most southern promontory of Asia, in 1° 15' N. lat., and Cape Romania in 1° 17', constitute the two extremities of the Straits of Singapore. The peninsula lies between 98° and 104° E. long. It is 750 miles long, with a width varying between 60 and 180 miles. The area is estimated at 45,000 square miles.

The peninsula is traversed by a mountain range, which has several peaks 3000 feet high, while a few of the mountains attain an elevation of 6000 feet.

The comparatively small width of this peninsula and the disposition of the mountain range prevent the formation of considerable rivers. The largest which are known are the Muar and the Pahang; the former falls into the Straits of Malacca, and the latter into the Chinese Sea. The number of small rivers is very great, and there probably is no country better watered than this peninsula.

The climate differs on the eastern and western sides of the peninsula, according to the peculiar action of the monsoons. The eastern side is most affected by the N.E. monsoon; the western in part by the S.W. monsoon, but is in part sheltered from both monsoons.

The soil seems not to be distinguished by fertility. The plants cultivated are chiefly rice, pepper, cotton, coffee, and a great variety of fruits.

Cattle are few in number, but buffaloes abound. No sheep are kept; hogs and fowls are plentiful. In the uncultivated tracts and woods tigers, leopards, and rhinoceroses are frequently met with, and sometimes elephants. Among the birds, that kind of swallow which makes the edible nests is the most remarkable.

The most important articles of commerce are from the mineral kingdom. Gold and tin are plentiful,

and are regularly exported—about 20,000 ounces of the former, and 2400 tons of the latter, annually.

The bulk of the population consists of Siamese and of Malays. The former occupy the isthmus of Krah and the districts north of $6^{\circ} 40' N.$ lat., and the latter the remainder of the peninsula. [MALAYS.] The entire population is computed to be about 200,000.

The northern part of the peninsula, as far south as the bay of Chai-ya, is immediately subject to the king of Siam. On that bay are two harbours, called Chai-ya and Bandon, and on the opposite western coast the harbour of Plunga or Pongo. The district between the bay of Chai-ya and Cajoe Patani is partly governed by Malay sovereigns, dependent on the king of Siam, and partly belongs immediately to Siam. The kingdoms of Calantan and Tringano on the eastern, and that of Queda on the western side of the peninsula, are only nominally dependent on Siam. Tringano, situated at the mouth of the little river Tringano, seems to be a considerable place. Two other towns are Queda and Alustar. The British colony of Penang, or Prince of Wales Island, is partly situated within the kingdom of Queda. The southern extremity of the peninsula is divided between the kingdoms of Pahang and Johore on the eastern side, that of Rumbowé in the interior, and those of Salangore and Perak on the western coast, together with the British colony of Malacca. These kingdoms are independent, and under the protection of the British.

MALAYS, a nation of southern Asia, who occupy the shores of the Malay Peninsula, and the larger islands of the Indian Archipelago. In person the Malays are short, squat, and robust. The face is of a round form, the mouth is wide, and the teeth remarkably fine. The chin is rather of a square form; the angles of the lower jaw are very prominent. The cheek-bones are high, and the cheek consequently rather hollow. The nose is short and small, never prominent, but never flat. The eyes are small, and always black. The complexion is generally brown. The hair is long, lank, harsh, and always black.

The Malays have made considerable progress in civilization, but more in the island of Java than on the other islands of the Indian Archipelago. They are well acquainted with agriculture and some of the mechanical arts. They have also made some progress in medicine and music. They are undoubtedly more civilized than any of the nations of southern Asia which inhabit the countries between China and Hindustan. Most of them are Mohammedans.

In the larger islands the Malay population generally occupies only the lower tracts along the coast, and the original inhabitants have retired before them into the interior.

MALCOLM, SIR JOHN, G.C.B. and K.L.S., was born at Eskdale, Dumfriesshire, Scotland, in 1769. He went early to Hindustan, and was engaged in the wars against Tippoo Sahib and the Mahrattas; but his chief employments, and those in which he most distinguished himself, were in his diplomatic missions to the court of Persia. He was successively governor of Mysore and Bombay. He wrote a valuable 'History of Persia,' a 'Political History of India,' and a 'Life of Lord Clive.' He died in 1836.

MALDIVES, or MALEDIVA ISLANDS, lie in the Indian Ocean, and extend nearly on one meridian from $7^{\circ} 6' N.$ lat. to $0^{\circ} 40' S.$ lat., or nearly 550 miles; but in no part is the breadth of the chain supposed to exceed 50 miles in a direct line. The most northern group or Atoll is about 350 miles from Cape Comorin, the nearest point of Hindustan. The islands are upwards of 1000 in number. They are inclosed and protected from the sea, which during the south-west monsoon is violently agitated, by narrow strips of coral reefs, which surround them like a wall. This protecting wall in many places scarcely reaches the surface of the water; in other places it forms a long sandy beach, perhaps less than six feet above the level of the sea, and is either circular or oblong. Each of these circular inclosures contains breaks, which constitute convenient passages for vessels or boats to enter. The channels which divide these Atolls, or Atollons (for so they are called), are in some places deep and safe, and are navigable by ships.

Within the Atolls the sea is not agitated by storms, and there are always soundings in twenty or thirty fathoms' water. The islands are generally situated along the inclosing coral wall, the central part of the Atolls containing only few of them. They are all small; not many of them exceed a mile in length and breadth, and a few are less than half a mile. They are generally circular or lozenge-shaped. Many are mere narrow strips, 50 or 100 yards broad, forming a circle, which incloses a lower tract, filled up with broken coral rocks, and dry at spring tides. Within this ring there is sometimes a considerable depth of water, from one to ten fathoms, so that a perfect lagoon is formed. The highest part of the islands is from 6 to 14 feet above water.

All the islands are covered with a thick impenetrable jungle, among which there are many fine large trees. A little Indian corn, sugar, cotton, and millet are cultivated. There are few animals on the islands, but fish is abundant on the shores. The climate is pleasant, but not healthy to Europeans.

The inhabitants are Mohammedans. Two languages are in use among them; the common, which seems to be peculiar to the people, and the Arabic, as a learned language. They have also a peculiar alphabet. The whole population may amount to between 150,000 and 200,000. They carry on a little trade with Bengal. They are ruled by a chief, called the Sultan, who pays tribute to the British governor of Ceylon. He resides on the Mali or Maldiva Atoll, which contains the largest of the islands, called Mali; its circumference is about seven miles.

MALDON. [ESSEX.]

MALE FERN, the rhizoma, incorrectly termed root, of the *Nephrodium Filix Mas*, has been celebrated from ancient times as an anthelmintic. The root-stock of young plants should be collected in spring or summer, and a fresh supply obtained every year, as a change occurs in the part a few months after being collected. It should be quickly dried, and preserved in glass or earthenware vessels in a dry place. The interior should exhibit a greenish colour, and possess a disagreeable odour, with a bitter, harsh, astringent taste.

It consists of an oil (which may be extracted by

sulphuric ether), resin, tannin, sugar, starch, and woody fibre. The oil, which is of two distinct kinds, one pure and the other united with resin and an extractive, is the active principle. Formerly a powder of the whole substance was administered; but, as the dose of this is bulky, Peschier has recommended pills of the ethereal extract, which are found to be very efficacious against that kind of tape-worm which is denominated the *Bothriocephalus latus*, or Broad Tape-worm. The common mode of administering it is to give a certain number of pills at night, and a like number in the morning, followed by some brisk cathartic, as the male fern only kills but does not expel the worm.

MALEBRANCHE, NICOLAS, one of the most illustrious disciples of Des Cartes, who both gave to his master's views a wider development, and imparted to them clearness and vivacity, was born at Paris, 1638. His attention was directed to philosophy by accidentally meeting with the work of Des Cartes, 'De Homine.' Abandoning his previous literary pursuits, he devoted ten years to the examination of the Cartesian philosophy, and acquired the reputation of surpassing all his contemporaries in a knowledge of its true spirit and tendency. As the result of his philosophical meditations, he published, in 1673, the first book of the 'Recherche de la Vérité,' which was quickly followed by the other five.

The philosophical writings of Malebranche are both elegant and perspicuous: neither the clearness of the thought is sacrificed to the graces of composition, nor the ornaments of language to simplicity. If the profound originality of his ideas gained him any admirers, the novelty and boldness of his assumptions exposed him to much opposition.

The other works of Malebranche were partly controversial and partly religious. Of the latter we may mention the 'Entretiens d'un Philosophe Chrétien et d'un Philosophe Chinois sur la Nature de Dieu,' Paris, 1708; 'De la Nature et de la Grace,' Amsterdam, 1680. The following are of a mystical character, blending religion with metaphysics:—'Traité de la Morale,' Rott., 1684; and 'Entretiens sur la Métaphysique et sur la Religion,' Rott., 1688.

MALEIC ACID. An isomeric or fumaric acid, obtained by distilling malic acid at a temperature of about 350°; it consists of H¹ C⁴ O³.

MALESHERBES, CHRÉTIEN GUILLAUME DE LAMOIGNON, the associate of Turgot and those illustrious statesmen who sought by moderate reforms to prop the weakness of the old monarchy of France, was born at Paris, December 16, 1721. Among other offices, he held those of president of the Cour des Aides, and minister of the king's household. When Louis XVI. was brought to trial, Malesherbes claimed the post of his defender. His fearless intrepidity entailed upon him the hatred and suspicions of the party in power, and he was guillotined April 22, 1794, meeting his fate with resignation.

MALESHERBIA/CEÆ, a natural order of polypetalous Exogens. The species are in many cases remarkable for the beauty of their yellow or blue flowers, and have been cultivated in this country, their seeds having been brought from Chili and Peru. They are, however, seldom seen, and are of no known use.

MALHERBE, FRANÇOIS DE, was born in

1555, at Caen, in Normandy. He accompanied Henri of Angoulême, son of Henri II., who went to Provence as governor in 1579, and remained attached to his household till that prince's death in 1585. He was patronized by Henri IV., upon whose death his widow, Mary de' Medicis, settled a pension upon him. He died in 1628.

Malherbe has been styled by competent judges the restorer of the French language and poetry. The eulogium bestowed upon him by Boileau is well known:—

'Enfin Malherbe vint, et le premier en France
S'it sentir dans les vers une juste cadence.'

MALIBRAN, MARIA FELICIA, afterwards Madame de Beriot, one of the most distinguished singers of any age or country, was born in Paris in 1808. When eight years old she was brought to England, where she remained for eight years, acquiring a thorough knowledge of the English language, and cultivating her musical gifts with the utmost assiduity. Her father was a man of fierce temper, but an excellent musician, and he taught his daughter the principles of the art, a knowledge which, unfortunately, few singers have ever possessed. She made her *début* in London as Rosina, in the 'Barber of Seville,' June 7, 1825, and her success was so marked that she was engaged as one of the principal singers at the York festival of that year. She then paid a visit to the United States, where she was induced to accept the hand of a man of double her age, M. Malibran, a merchant and banker, who was reputed to be enormously rich. The marriage in every respect proved unfortunate. Her husband treated her harshly, and soon afterwards becoming bankrupt, was thrown into prison. Malibran immediately abandoned to the creditors the provision that had been made for her by the marriage settlements; and separating from her husband, returned to Europe. In 1828 she appeared at Paris in the opera of 'Semiramide.' Her success was immense; she became the favourite of the fastidious Parisian public, and played a long rôle of characters with an ability which justified the enthusiasm which she evoked. In 'tender strokes of art,' in vivacity, feeling, and the display of the gentler emotions, she showed herself unrivalled.

Her next engagement was at the London Italian Opera, where she appeared on the 21st March, 1829, and during the season played a wide range of characters—Desdemona, Rosina, Semiramide, Romeo, Tancredi, Ninetta, and Zerlina. From that time to the day of her death she remained the idol of the British public, who admired not only the depth and extent of her passionate genius, but the force and purity of her moral character.

The incidents of a successful artist's career are neither many nor interesting. We pass on to her melancholy end, which was undoubtedly hastened by her incessant labour. In March, 1836, having been regularly divorced from M. Malibran, she married the celebrated violinist, De Beriot, and after a brilliant season of English operatic performances at Drury Lane, repaired to Manchester in September, to fulfil an engagement at the great festival. Worn out with her long-continued exertions, and aware that repose was absolutely essential to her health, she could not consent to disappoint the public, and sung at the morning and evening concerts of Wednesday, the 14th

September, with a splendour and power which surpassed all her former efforts. But while the rapturous plaudits of her admirers 'rent the air,' she lay in a state of syncope from exhaustion. She was bled, and removed to her home, where she expired on the 23rd of September, in the twenty-ninth year of her age.

MALIC ACID (Lat. *Malum*, 'an apple') was discovered in 1785 by Scheele. It received its name from having been first obtained from the juice of apples, in which it exists in considerable quantity; but it also exists in many other fruits, and in the berries of the mountain ash. Malic acid is colourless, inodorous, very sour to the taste, and acts strongly on vegetable blues; in a moist air it is deliquescent; it is very soluble both in water and in alcohol. Nitric acid converts it into oxalic acid. Its saline compounds are called malates, some of which exist in nature. They are not an important class of salts.

Malic and citric acids are isomeric bodies, both being composed of, when anhydrous, $C_3H_4O_5 \cdot 2H_2O$.

The crystals contain one equivalent of water; whereas those of citric acid contain different proportions of it, according to the circumstances under which they are formed.

When malic acid is subjected to a heat of about 350° Fahr., it is decomposed, and the results are two isomeric pyro-acids, namely, maleic or equisetie, and the fumaric or pyromalic acids.

MALICE OR DOLE is defined in Scotch law to be a corrupt or evil intention in the mind of a person, prompting and inducing him to commit a criminal act, and forms an essential element in all crimes. In most crimes the nature of the act is sufficient evidence of the existence of dole. It is not necessary to constitute a crime that the malice should be directed against any particular person: nor is it indispensable in all cases that there should be evidence to show an intention on the part of the accused to commit the particular crime with which he is charged. Wherever there is undoubted proof of a fixed and settled resolution to do some violent and atrocious mischief, even although the event may turn out more disastrous than the pannel originally intended, he is in the estimation of the law as culpable as if he had foreseen and compassed all that had happened. (Hume, Com. I. 25.) In civil actions for slander, malice is in the ordinary case presumed, the insult or injury complained of being sufficient evidence of its existence.

MALICIOUS INJURIES. The law relating to malicious injuries to property was amended and consolidated by the 24 and 25 Vict. c. 97. The injuries, such as arson, destruction of works of art, injuries to buildings, manufactures, trees, vegetable productions, fences, mines, sea and river banks, ponds, bridges, viaducts, cattle, vessels, are all provided for by this Act, and the different degrees of punishment established.

MALINES. [MECHELEN.]

MALL or **PALL MALL**, the name given to those places in London, and other English towns, where there were formerly alleys for playing at tennis. The word is derived from the mallet with which the ball was struck, and which was sometimes called by the compound name pall-mall, from the Italian *palla*, 'a ball.'

MALLARD. [DUCKS.]

MALLEABILITY is that property of certain metals which admits of their being extended by the blows of a hammer or by pressure. In this quality gold exceeds all other metals; thus, the gold-leaf sold in books is so extremely thin, that less than 5 grains cover about 270 square inches, and the thickness of each leaf does not exceed $\frac{1}{100000}$ part of an inch. The order in which malleable metals exhibit this property is as follows:—Gold, silver, copper, platinum, palladium, iron, aluminium, tin, zinc, lead, cadmium, nickel, cobalt. Metals which are malleable are also ductile, that is, they may be drawn into wire. Iron which has been made hot by hammering loses its malleability, and cannot be again hammered till it has been annealed.

MALLEACEA, or **MALLEIDÆ**, a family of monomyarian Conchifers or bivalve Shells, according to the system of Lamarck, most of the genera of which are to be found in the family *Margaritacea* of De Blainville. They belong to the *Ostracea* of Cuvier, and the *Oxygonæ* of Latreille.

Animal, with the mantle non-adherent, entirely open in its whole circumference, without tube or particular opening, prolonged into irregular lobes, especially backwards; foot canaliculated, and almost always furnished with a byssus.

Shell, black or horn colour, inequivalve, inequilateral, very irregular; hinge without teeth; marginal ligament sublinear, simple, or interrupted by crenulations; muscular impression subcentral, fixed generally by a byssus furnished by the animal.

We may enumerate the following genera:—*Posidonia* (fossil); *Vulsella* (seas of warm climates); *Crenatula* (seas of India and Australia, and also of South America); *Perna* (Indian Ocean); *Malleus* (East and West Indies, Australasia); *Gervillia* (fossil); *Inoceramus* (fossil); *Catillus* (fossil); *Pulvinites* (fossil). Lamarck places *Avicula* [AVICULA] among the *Malleacea*, but M. de Blainville arranges it within the circle of his family *Margaritacea*, and M. Rang regards it as the type of a family which he terms '*Les Aviculés*.' The fossil species of *Malleacea* are very numerous.

(See Deshayes, Professor Phillips, Mr. Lonsdale, Dr. Fitton, Dr. Mantell, Professor Sedgwick, Sir R. I. Murchison, and others.)

MALLET, DAVID, was born about the year 1700, at Crieff, in Perthshire, died 1765. He studied at the University of Edinburgh, made the tour of Europe as tutor to the sons of the duke of Montrose, and ultimately settled in London. He is known from his ballad of 'Margaret's Ghost,' and his tragedies of 'Eurydice,' 'Mustapha,' and 'Elvira.'

MALLORCA. [BALEARIC ISLANDS.]

MALLOW. [CORK.]

MALLOW, MARSH. [ALTHÆA OFFICINALIS.]

MALMESBURY. [WILTSHIRE.]

MALMESBURY, WILLIAM OF, one of the most valuable of our old historians, is said to have been born in Somersetshire, about 1095 or 1096. When a boy, he was placed in the monastery whence he derived his name, where in due time he became librarian, and according to Leland, precentor. He is generally supposed to have died about 1143. His principal writings are—'*De Gestis Regum*' (the history of the kings of England); '*Historiæ Novellæ*' (the modern

history); and 'De Gestis Pontificum' (the history of the prelates of England), containing an account of the bishops and of the principal monasteries, from the conversion of the English by St. Austin to 1125. These were published by Sir Henry Savile among the 'Scriptores post Bedam,' folio, 1596, reprinted, folio, Francof., 1601. English translations of these, and of some of his other works, have been published.

MALMESBURY, JAMES HARRIS, EARL OF, was the only son of James Harris, the author of 'Hermes' and other well-known philological works. He was born at Salisbury, April 21, 1746. On leaving Oxford in 1765, he was sent for a year to study at Leyden. He then, after being eight months at home, set out in 1767 on a short continental tour; and in the autumn of the same year, through the patronage of Lord Shelburne, was appointed secretary of embassy at Madrid. The temper and firmness, as well as talent, with which he managed the negotiation with regard to the Falkland Islands, gave so much satisfaction to his government, that he was the following year appointed to the post of minister at the court of Berlin. He retained this mission for four years. In 1777 he was sent as ambassador to St. Petersburg, and having in the meantime received the Order of the Bath in 1780, he remained in Russia till his health compelled him to return home in 1784. In 1788 Mr. Pitt offered Sir James Harris the post of minister at the Hague, which he accepted. While at the Hague, he succeeded in negotiating, in April 1788, the treaties of alliance with Holland and with Prussia, by which the power of the stadtholder was at that time preserved from being overthrown by the democratic party. For this service, Sir James was raised to the peerage as Baron Malmesbury.

Lord Malmesbury continued to act with the Whig party in Parliament till 1793, when he formed one of the body of the friends of Mr. Fox who went over to ministers with Burke and the duke of Portland. Lord Malmesbury was now sent by Mr. Pitt on a mission to Berlin, where he prevailed upon the new king of Prussia to enter into a second alliance with England and Holland. In 1794 he was employed to negotiate the marriage between the Prince of Wales and Caroline, the daughter of the duke of Brunswick, and accompanied her to England.

His last missions were in 1796 and 1797 to Paris and Lisle, to negotiate a peace with the French Republic, and which were attended with no result. In 1800 he was created Earl of Malmesbury and Viscount Fitzharris. He died in London, November 20, 1820, leaving a son, who succeeded him in the title, and three daughters.

MALMÖ, a strongly fortified town in the Swedish division of Malmölan, is situated about 55° 40' N. lat., and near 13° E. long. It is built on the widest part of the Sound, nearly opposite the town of Copenhagen, on level ground, and has a good and safe harbour, protected by the fortress of Malmöhus. The town is well built, and has regular streets. In the middle is a fine square, 166 yards long and 144 wide. The inhabitants (in 1861, 20,149 in number) carry on an active commerce in corn. Cloth, stockings, hats, gloves, carpets, soap, leather, starch, and looking-glasses are made. Malmö has a citadel and a port, consisting of an artificial inner harbour, and an outer roadstead.

VOL. VIII.

MALMSEY, (so called from having been first made at Malvasia in the Morea), a luscious and high-flavoured wine made in the island of Madeira from grapes of a peculiar kind, which are suffered to attain the last stage of ripeness before they are gathered. Malmsey wine has much body, and will retain its good qualities for a long time. When newly made, Malmsey Madeira is of the same golden hue as the ordinary wine of the island, but its colour is materially deepened by age. It contains 16 to 17 per cent. of alcohol. Malmsey wine is also made in the island of Teneriffe, but the quality is greatly inferior to that of Madeira.

MALO, ST. [ILLE-ET-VILAINE.]

MALOPE, a genus of malvaceous plants, consisting of two species, one of which is commonly cultivated as a favourite hardy annual. This plant, *Malope malacoides*, is common in Barbary, where it is found among stones and rocks, which it ornaments with its large crimson flowers; it is also met with in Sardinia and other parts of the south of Europe.

MALPAS. [CHESHIRE.]

MALPIGHI, MARCELLUS, was born near Bologna in 1628. He studied medicine in that university, and in 1653 received his doctor's degree. He is now chiefly remembered in connection with his discoveries in the anatomy of the skin and of the secreting glands. He first described clearly the structure of the tongue. He proved that the colour of the skin depends on the rete mucosum, the cutis of white and of coloured races being always of the same rosy hue. He was the first who examined the circulation with the microscope. He published also some excellent observations on the chemical and other characters of the blood; and his works on the process of incubation, and on the structure and physiology of plants, though now almost forgotten, must have been very important additions to the knowledge of his day.

MALPLAQUET, a village in France, department du Nord, 16 miles N.N.W. of Avesnes. It is only remarkable as the scene of the great battle, August 11, 1709, in which Marlborough and Prince Eugene defeated the French under the Marshals Villars and de Boufflers. The allies mustered 93,000 men, with 105 guns; the French, 95,000 men, with 80 guns; but the latter were very strongly posted, on a range of wooded heights, bristling with redoubts and palisades, stockades and abbatiss, which were only approachable by two defiles, locally called *Trouées*, and these completely under fire. By means of repeated and desperate charges, combined with a formidable attack in the rear, Marlborough succeeded in forcing the enemy's lines, and compelling them to retreat upon Bavai. This success, however, was dearly purchased; the allies lost 5544 killed, and 12,706 wounded or missing; the French, about 14,000.

MALT (Ger. *malz*, from *malin*, 'to grind'), is grain, usually barley, which has become sweet and more soluble in water, from the conversion of its starch into sugar by artificial germination to a certain extent, after which the process is stopped by the application of heat. The making of malt, called *Malting*, is thus conducted:—

The barley is steeped in cold water for a period which (as regulated by law) must not be less than

C C

forty hours; but beyond that period the steeping may be continued as long as it is thought proper. Here it imbibes moisture, and increases in bulk; at the same time a quantity of carbonic acid is emitted, and a part of the substance of the barley is dissolved by the steep-water. 100 bushels of grain, after being steeped, swell to the bulk of 120 bushels, and increase 47 per cent. in weight; and the quantity of matter which the steep-water holds in solution varies from 1-50th to 1-100th of the weight of barley. It consists chiefly of an extractive matter of a yellow colour and disagreeable bitter taste. After the grain has remained a sufficient time in the steep, the water is drained off, and the barley thrown out of the cistern upon the malt-floor, where it is formed into a heap called the *couch*, about 16 inches deep. In this situation it is allowed to remain about twenty-six hours. It is then turned by means of wooden shovels, and diminished a little in depth. This turning is repeated twice a day or oftener, and the grain is spread thinner and thinner, till at last its depth does not exceed a few inches.

When placed in a couch, it begins gradually to absorb oxygen from the atmosphere, and to convert it into carbonic acid, at first very slowly, but afterwards more rapidly. The temperature, at first the same with that of the external air, begins slowly to increase; and in about ninety-six hours the grain is at an average about 10° hotter than the surrounding atmosphere. At this time the grain, which had become dry on the surface, becomes again so moist that it will wet the hand, and exhales at the same time an agreeable odour, not unlike that of apples. At the time of this moistening, which is called *sweating*, the roots of the grains begin to appear, at first like a small white prominence at the bottom of each seed, which soon divides itself into three rootlets, and increases in length with very great rapidity, unless checked by turning the malt. About a day after the sprouting of the roots, the rudiments of the future stem, called *acrospire*, may be seen to lengthen. It rises from the same extremity of the seed with the root, and advancing within the husk, at last issues from the opposite end; but the process of malting is stopped before it has made such progress.

As the acrospire shoots along the grain, the appearance of the kernel, or mealy part of the corn, undergoes a considerable change. The glutinous and mucilaginous matter is taken up and removed, the colour becomes white, and the texture so loose that it crumbles to powder between the fingers. The object of malting is to produce this change: when it is accomplished, which takes place when the acrospire has come near to the end of the seed, the process is stopped by drying the malt upon the kiln. The temperature at first does not exceed 90°; but it is raised very slowly up to 140° or higher, according to circumstances. The malt is then cleared, to separate the rootlets, which are considered injurious.

The subsequent processes of brewing and distillation of spirits are described in the articles *BREWING* and *DISTILLATION*.

In brewing ale, porter, and table-beer, three different kinds of malt are employed, which are known as pale or amber, brown, and black or roasted malt—sometimes called patent malt. The pale or amber malt yields the saccharine or fermentable

extract; the brown malt is not fermentable, but is used to impart flavour; and the roasted malt is employed, instead of burnt sugar, merely to give colouring matter to porter. In the brown and roasted malts the sugar appears to be entirely converted into gum and colouring and extractive matters; and hence they are incapable of undergoing fermentation. The brown malt is subjected to a higher temperature in drying than the pale malt, and by a still further exposure to heat in revolving cylinders or roasters it is converted into black or patent malt.

It is generally believed that the excise duty has had the effect, both of limiting the quantity of malt made, and also of checking any improvements in the making. The malt duty was first levied in England in 1697, in Scotland in 1713, and in Ireland in 1783. In the hundred years from 1716 to 1816 there was scarcely any increase in the quantity of malt made in England, the amount never varying far from 24 million bushels in a year. This stationary condition, at a time when the population was steadily increasing, was partly attributed to an increasing taste for tea and coffee, but was chiefly owing to the effect of the duty and restriction. The duty rose gradually from 6*d.* per bushel in 1702 to 4*s.* 6*d.* in 1804: it is now 2*s.* 7*d.* and 5 per cent., or a fraction under 2*s.* 9*d.* per bushel. Since 1830 the quantity paying duty has varied from 30 to 50 million bushels annually. The price has varied from 2*s.* 6*d.* to 10*s.* 6*d.* per bushel, during a century and a half, the average price being 4*s.* 6*d.* The excise regulations were so very stringent in past years that maltsters scarcely knew in what manner to conduct their business. An Act passed to regulate the trade in 1827 contained no fewer than eighty-three clauses, many of which were difficult of interpretation, and more than 100 penalties were enforced under it in less than three years. This was replaced by a better statute in 1830, and since that time several other Acts have been passed to facilitate the operations of the maltster, without endangering the revenue.

The following were the quantities of malt retained for home consumption in the United Kingdom in the years 1858 to 1865, inclusive:—

Years.	Bushels.	Years.	Bushels.
1858 ...	45,105,773	1862 ...	43,688,608
1859 ...	47,746,289	1863 ...	49,072,815
1860 ...	41,754,050	1864 ...	51,796,978
1861 ...	46,650,100	1865 ...	48,946,497

The excise revenue derived from malt during the preceding period will be found in the article *INLAND REVENUE*.

To meet the objection of agriculturists, who urged that the duty prevented them from using malt for the feeding of cattle, an Act was passed in 1864 by which it was allowed to be used for that purpose free of duty, provided it was mixed with a certain proportion of linseed meal, so as to render it unfit for brewing. The Act is, however, to all intents a dead letter, only twenty-eight persons ever having availed themselves of its provisions, and there are at present less than half that number. The Inland Revenue Commissioners in their last report, assert

that the failure of the measure is not to be attributed to the excise restrictions.

In 1865 another Act was passed with the view of removing an objection urged by maltsters, to the effect that the assessment of the duty at so much per bushel, was often unfair in consequence of the difference in the quality of the barley. It is, therefore, now open to the maltster to have the duty charged by weight if he desires it—the standard being fixed at 53 lbs. per bushel.

But nothing less than the total repeal of the duty would seem to satisfy the agriculturists, who maintain that it most seriously interferes with the cultivation of barley, and that the impost is altogether opposed to the principles of free trade. For some years past they have carried on a vigorous, but as yet (1866), unsuccessful agitation to effect their object.

MALTA. The Maltese islands, in the Mediterranean, lie between 35° 49' and 36° N. lat., and 14° 10' and 14° 36' E. long. Malta is 58 miles from the nearest point of Sicily, and 179 from Cape Demas, the nearest point of Africa. Its greatest length is 17½ miles; its greatest breadth is 8¼ miles. The population in 1861 was 131,647 Maltese, 1274 British, and 1134 foreigners; total, 134,055. The mean temperature of the year is 67°, in summer 78°, in winter 57° Fabr. The government is administered by a governor, who is assisted by a council of eighteen members, ten official and eight elected. The annual revenue is about 150,000*l.* and the expenditure often somewhat in excess of that amount. The total military expenditure, defrayed by the English government, for the defence of Malta is about 330,000*l.* per annum, of which only 6000*l.* is provided by the island authorities. The total exports from the country are valued at 3,000,000*l.* per annum, and the imports at 2,250,000*l.* About two-fifths of the shipping employed belong to Italy.

The imports from Malta into the United Kingdom have been gradually decreasing during the last few years. In 1860 they were valued at 195,390*l.*; in 1864 at only 128,013*l.* The chief articles were cotton, silk, and olive oil. The exports from this country to Malta consist, principally, of cotton manufactures, coals, gunpowder, linens, and woollens. The value of the whole exports in 1864 was 870,798*l.*, of which 753,113*l.* consisted of the produce and manufactures of the United Kingdom, and 117,685*l.* of foreign and colonial merchandise. Malta contains two principal ports on the south-east side of the island, which are separated by a tongue of land a mile and a half long, on which are built the castle of St. Elmo and a lighthouse, commanding the entrance to both ports. This tongue of land is 200 feet above the level of the sea, but declines towards the point, and is almost flat at the part where it joins the mainland. On this advantageous position is built the modern city of *Valetta*, which is the seat of the government, and the citadel of the island. It is so strongly fortified as to render the island almost impregnable. The whole works have embrasures and accommodation for upwards of 1000 guns.

The great harbour, which is to the eastward of *Valetta*, is about 3400 yards in length, with an entrance 450 yards wide, defended by a strong fort opposite the castle of St. Elmo, called *Ricasoli*, which crosses its fire, but is commanded by that

castle. The harbour varies in width from 700 to 450 yards, and is surrounded by all the requisite buildings for a naval arsenal: it is one of the finest harbours and naval stations in the Mediterranean. The harbour to the westward, which is called *Marsamuscetto* (a word signifying, in Arabic, 'a place of shelter'), has at its entrance, opposite to and besides the castle of St. Elmo, a small but powerful fort called *Fort Tigné*. It is principally appropriated to vessels arriving from the Levant, and has a large quarantine establishment. Besides these two harbours, there are several bays which ships sometimes enter in stress of weather.

The whole of the southern coast of the island is by nature inaccessible. The rocks rise perpendicularly from the sea to the height of several hundred feet. The island slopes from the southern to the northern side.

The small islands of *Gozo*, *Comino*, and *Filfa* belong to the group of the Maltese islands. *Gozo* is 10 miles long by 5½ wide. In the centre of the island is a ruinous castle, at the foot of which is a populous town called the *Rabbato*. The other two islands are much smaller.

The scene on entering the port of Malta is one of the most striking and beautiful that can be conceived. This magnificent harbour is surrounded with bastions, over which appear handsome buildings and the towers of numerous churches, all built of stone, and presenting the cleanest and most brilliant appearance. On one side stands the city of *Valetta*, towering above the harbour; on the other the three cities of *Vittoriosa*, *Cospicua*, and *Senglea* (commonly called the *Borgo*, *Burmola*, and *Isola*), which in fact form one continued town, covering the two spits of land which project from the eastern side of the harbour like pointing fingers, and forming the inlets or coves already mentioned. *Valetta* and these three cities compose the capital of Malta. *Valetta* is inhabited by official and wealthy persons, and the three opposite cities by manufacturers and traders. The eastern part of the island is separated from the western by a ridge of land which crosses to the westward of *Valetta*, and forms a natural fortification. The island is thus divided into two parts, of which the eastern contains the ancient capital and twenty-two casals or villages. *Città Vecchia*, or the old city, as it is commonly called, but the proper name of which is *Città Notabile*, is situated on a rising ground in the interior of the island, about 6 miles from *Valetta*, and was, before the foundation of the latter city, the capital of the island. It is still the seat of the bishopric, and contains the cathedral, a handsome modern edifice, built on the site of the ancient church. The city is walled, but is of no importance as a fortification. It contains many good and even magnificent buildings, but, with the exception of two large convents, the population is very trifling. A populous suburb, called the *Rabbato*, is inhabited by the dependents of many convents and ecclesiastical establishments in the neighbourhood, and by a large agricultural population. There are extensive catacombs cut in the calcareous rock. The parish churches of the casals are large and magnificent: they are built of the stone of the island, and, being isolated, and well situated in the centre of the habitations, display

their architecture to advantage. Malta is chiefly supplied with water by rain, carefully preserved in tanks; but there is a magnificent viaduct, $8\frac{1}{2}$ miles long, which brings water to Valetta from a spring.

The surface of Malta and Gozo is estimated at 114 square miles, or 72,960 acres, of which about two-thirds are cultivated, and the remaining third is bare rock. There is much good native earth in the valleys, which has been converted into productive fields; but a great portion of the land has been brought to its present state of culture by the industrious native, who with great labour and expense cuts away the hard surface of the rock, and frequently finds a quantity of earth lying inert in the crevices and interstices beneath. The produce of Malta is cotton (which is its staple), wheat, barley, pulse, potatoes, barilla, cummin seed, and sullar, or the French honey-suckle, which is used for fodder. As there is no meadow-land, much barley is cut when green for draught animals; and the straw (which is very fine) is a good substitute for hay. There are no wild animals in the island, and, from the scarcity of pasture, very few cattle are bred. Meat is principally imported from Barbary. Horses are also imported, but some mules are reared, and the asses of Malta and Gozo are much prized, as are also the goats.

The roads in Malta and Gozo, generally speaking, are good, and communicate with all parts of each island. The inland modes of transport are by single-horse carts, and horses, mules, or asses of burden.

These islands enjoy an excellent climate. Its worst feature is the peculiar sirocco wind which prevails for a few weeks in autumn. Malta is eminently fitted for the residence of English invalids from the beginning of October to the end of May.

The natives of Malta are a dark-skinned athletic race, and on that account, and from their Arabic dialect, have often been considered of African origin; but we look in vain for the Arab features. They are hardy and robust. The great bulk of the people who are employed in field-labour are stone-cutters. The Maltese are also excellent seamen, and are esteemed such in all the ports of the Mediterranean.

The Italian language was introduced into these islands during the existence of the Sicilian government, and has ever since been in use, chiefly among the upper, and partly also among the middle classes of the inhabitants of the towns, in addition to their native tongue. The mother-tongue of the people, the Maltese, is used in the country parts and at Gozo, and also among the poorer classes in the towns. A knowledge of the English language is spreading in Malta. There are a university and a high school for the children of the upper classes, and many primary schools.

The religion of the people is the Roman Catholic. The clergy and chapels are numerous. The Protestant clergy and places of worship (consequent on the occupation of the island by the English) are much fewer in number. A church was built on the island by Queen Adelaide about 1840.

Malta is a crown colony, and the local government is conducted by a governor, who, in legislative matters, is assisted by a council of six persons nominated by the Crown. The courts of justice are numerous, and the procedure has been condemned as intricate and costly.

History.—The earliest notice of the Maltese islands is in Diodorus of Sicily (v. 12), in which he says that Malta was a Phenician colony. It is supposed to have been afterwards occupied by the Greeks. The Carthaginians obtained possession of it in B.C. 402; and the Romans in B.C. 242. The Arabs seized it in 870; but in 1120 Count Roger, the Norman conqueror of Sicily, took possession of Malta, and expelled the Arabs. Malta was thus attached to the island of Sicily, and it became subject to the different dynasties which successively governed that island.

In 1516 Sicily, with the Maltese islands, passed to the Emperor Charles V., as heir to the crown of Arragon. On the 4th of March, 1530, Charles granted to the grand-master and religious fraternity of St. John, who had recently been expelled from Rhodes by the Turks, the ownership of all the castles, fortresses, and isles of Malta and Gozo, with complete jurisdiction. The sovereignty of Malta was by this grant in effect surrendered to the Knights, though the form of tenure from the crown of Sicily was maintained by the reservation of the annual payment of a falcon to the king of Sicily or his viceroy. The Knights built formidable defences, and speedily improved the condition of the island. On the 9th of June, 1798, the French expedition to Egypt under Bonaparte, consisting of eighteen ships of the line, eighteen frigates, and about 400 transports, having 40,000 men on board, arrived off the island. The pusillanimity of the grand-master, Ferdinand Hompetch, and the treachery of some French knights of the Order, led to the surrender of Malta to this force, although it was amply fitted for defence. The French government soon became so oppressive that the Maltese revolted, and they besieged the fortified cities from September, 1798, till September, 1800, whilst a blockade was kept up by sea by the Sicilian, Portuguese, and English. Captain Alexander John Ball, who commanded the squadron afterwards appointed by Lord Nelson to besiege Valetta, was in the beginning of 1799 elected by the Maltese as their chief, and the president of their congress. At length General Vaubois made proposals to surrender the place into the hands of the English troops. This act was signed and concluded on the 5th of September, 1800.

At the Peace of Amiens in 1802, it was settled between Great Britain and the French republic that the island should be restored to the Knights of St. John, and be an independent state as formerly, but with some modifications. Other political events prevented the fulfilment of this plan; and England remained in military possession of Malta till 1814. This was a period of great prosperity to the island, with the exception of a serious visitation of the plague in 1813. On the 30th of May, 1814, a definitive treaty of peace, concluded at Paris between France and the allied powers, fixed the lot of Malta, by a formal recognition of its subjection to the crown of Great Britain. But as the cessation of the war opened the ports of Europe, Malta lost much of her recently acquired prosperity. As a military and naval station, it has ever since been kept up with great care; and as a dependency or colony of England, many improvements in the internal government have been made since 1840. The head-quarters of

the Mediterranean fleet, and a dépôt on the route to India, its political importance is very great, and fortifications of an impregnable character have therefore been erected, with arsenals, storehouses, and other appliances.

MALTA, KNIGHTS OF, a celebrated military and religious order, known also by the names of Knights of St. John of Jerusalem, Knights Hospitallers, and Knights of Rhodes. The Order originated in a hospice which was founded at Jerusalem, about the middle of the eleventh century, for receiving the pilgrims from Europe who visited the holy sepulchre. When the crusaders under Godefroy de Bouillon took Jerusalem in 1099, several of them determined to join the institution, and to devote the rest of their lives to the service of the poor pilgrims. Godefroy de Bouillon made a donation of his own lordship of Montboire in Brabant to the hospice of St. John, and several other princes followed his example. The dress assumed by the new Hospitallers was black, with a white cross, having eight points or arms on the left breast. Pope Paschal II. sanctioned the new institution, the members of which bound themselves by solemn vows of chastity, individual poverty, and obedience, to which was afterwards added that of being always ready 'to fight against Mussulmans and all others who forsake the true religion.' For nearly two centuries the Hospitallers, together with the Templars, were the firmest support of the Christians in the East; and when Acre, the last bulwark of Christendom, was taken by the Mussulmans in 1291, the remains of the Order withdrew to Cyprus. In the year 1310 they took possession of the island of Rhodes, and strongly fortified its capital, from which they carried on by sea a deadly warfare against the Mussulmans. In 1522 Sultan Solymán the Great attacked Rhodes for the second time, and after an obstinate defence, captured it, and expelled the knights, who found refuge in Italy. In 1530 Charles V. gave to the Order the islands of Malta and Gozo. After the surrender of Malta to the French, in 1798, the Order as a sovereign body became extinct.

MALTHUS, REV. THOMAS ROBERT, was born in 1766. He was entered at Jesus College, Cambridge, in 1784, proceeded B.A., 1788, and M.A., 1797; took orders, and undertook the cure of a small parish in Surrey. In 1798 he published 'An Essay on the Principle of Population, as it affects the future improvement of Society, with Remarks on the Speculations of Mr. Godwin, M. Condorcet, and other Writers;' but finding that his facts and illustrations were imperfect, in 1799 he went abroad, and journeyed through Sweden, Norway, Finland, part of Prussia, France, and Switzerland, collecting materials for the second edition of his work, which he published in 1803. This work, and his 'Inquiry into the Nature and Progress of Rent,' are the most important of his works. He published many pamphlets of temporary interest, and died in 1834.

MALTON. [YORKSHIRE.]

MALURUS, the name of a genus of birds abundant in New South Wales. They belong to the *dentirostral*, or toothed-billed group of the order *Passeres*. Their characteristics are—bill short, with pretty wide gape; ridge keeled; tip curved, compressed; bristles at the angle of the gape; nostrils

placed in large furrows, surrounded by a membrane; tarsi long and slender; wings short, with ten primary feathers, the first short, the fourth, fifth, and sixth subequal and longest of all; tail tapering and narrow. The Blue Wren (*M. cyaneus*) of the colonists is the type of the genus. It is a beautiful bird, and noted as a singer.

MALUS, ETIENNE LOUIS, was born at Paris, June 23, 1775. On the formation of the École Polytechnique, Malus was admitted as a student, and on quitting the institution he was employed as a professor of mathematics in the military school at Metz; but having an inclination for a more active life, he entered the corps of engineers with the rank of captain, and in 1797 he was sent to join the army of the Sambre and Meuse. At the termination of the campaign, Malus went to Paris, and in the following year embarked with the expedition to Egypt under Bonaparte. He was engaged there in various actions, and superintended the fortifying of Damietta.

In 1801 he returned to France, married soon afterwards, and in 1810 was made lieutenant-colonel. During the rest of his life, all the time he could spare from his professional avocations was spent in the cultivation of the sciences, particularly in optical investigations; and his first published work was entitled 'Traité d'Optique.'

In 1808 the Institute of France having offered a premium for the best mémoire on the subject of double refraction in crystals, Malus entered zealously into this field of research; and while prosecuting his experiments, accidentally made the discovery, that when a pencil of light is reflected from unquicksilvered glass, at an angle of incidence equal to $54^{\circ} 35'$, or from the surface of water at an angle of incidence equal to $52^{\circ} 45'$, the reflected light possesses the same properties as are exhibited by one of the pencils produced by double refraction in a crystal. He observed, also, that when the pencil reflected from a transparent medium, at a certain angle of incidence, is made to fall on another such medium at an equal incidence, if the plane of the second reflection is coincident with the plane of the first, the light is reflected as usual; but if the planes are at right angles to one another, no reflection takes place at the second surface, the pencils of light being wholly refracted.

To the effect produced on light so reflected, he gave the name of polarization; and these phenomena may be said to have laid the foundation of a new branch of physical optics. Malus was immediately elected a member of the French Institute; and in 1811 the Royal Society of London awarded him the Rumford medal. He died in Paris, February 23, 1812, in the thirty-seventh year of his age.

MALVA, a genus of plants belonging to the natural order *Malvaceæ*. *M. moschata*, the Musk Mallow, is native in many parts of Europe, and is found in Britain in grassy borders of fields and by waysides. *M. sylvestris*, Common Mallow, grows on waste places and road sides in Britain, and is native in most parts of Europe. The whole plant, but especially the root, yields when boiled a plentiful tasteless mucilage, which is used in some cases of internal irritation. Decoctions of the leaves are employed in dysentery, and in general for removing

supposed acrimonious humours; but their chief utility is in clysters, fomentations, and poultices. This species is the Malva of Pliny. *M. rotundifolia*, Dwarf Mallow, is common in waste places in most parts of Europe, and is a native of Britain. *M. borealis* is found in Britain, near Hythe in Kent. There are many other species of Mallow. Those mentioned are the only natives of Britain, and the others are of little importance, excepting as ornamental plants.

MALVACEÆ are a large natural order of exogenous plants. A large proportion of the order consists of herbaceous or annual plants, inhabiting all the milder parts of the world, but much the most plentiful in hot countries, where alone a comparatively small number of species become trees. In many cases they are remarkable for the large size and beautiful colours of their flowers, which are, however, fugitive. Among the very numerous species several are of essential service to man. As emollients they are well known in medical practice, the Marsh Mallow (*Althea officinalis*) being one of the most useful among this kind of remedial substances, and a large proportion of the whole order being capable of supplying its place. The hairy covering of the seeds of the various species of *Gossypium* forms the raw cotton so important to our manufacturers. The seeds of *Hibiscus abelmoschus* are warm and musky, and are employed in perfumery as a substitute for musk; those of *Hibiscus esculentus* are used in hot countries as a mucilaginous ingredient in soups. A few species are acid, especially *Hibiscus sabdariffa*. The tenacious fibres procured from the inner bark of many kinds of malvaceous plants are formed into cordage. *Hibiscus elatus* and *H. tiliaceus*, and several kinds of *Sida*, are principally used for this purpose.

MALVERN. [WORCESTERSHIRE.]

MAMELUKES, or MEMLOOKS, the name of a military body which for a long time ruled Egypt. They were first instituted in the early part of the thirteenth century by Malek Salach, grandson of Safadeen, which Safadeen was the brother of the famous Salah Edeen, the Koord, the founder of the Eyoob dynasty of the sultans of Egypt, which succeeded the Fatimides. In 1517 Sultan Selim I. subdued Egypt, and put to death Toman Bey, the last of the Circassian dynasty. A pasha, who resided at Cairo, was appointed by the Porte; but the beys of the Memlooks, twenty-four in number, were the governors of as many districts, and continued almost independent of the Porte till Bonaparte's invasion, when the battle of the Pyramids, in July 1798, destroyed their power. After the English and the Turks had reconquered Egypt in 1801, the capitan pasha treacherously murdered several of the beys whom he had invited to a conference. At last, in 1811 Mehemet Ali, pasha of Egypt, by a similar contrivance, destroyed nearly all the remainder in the citadel of Cairo, and they are now extinct as a body. The Memlooks were recruited entirely from Caucasian slaves.

MAMERS. [SARTHE.]

MAMERTINE PRISONS, places of confinement at Rome, where state prisoners were incarcerated. They were built by Ancus Martius; and from what remains of them, more horrible dens could not be imagined. There were two of them, one above the

other; and the only entrance was by means of a small aperture at the top of the upper prison, down which the prisoner was let. In the same way there was another small opening to the lower subterranean chamber, where humidity and eternal darkness prevailed, without any chance of escape. Jugurtha was among the number of state prisoners who occupied these dreary abodes. They were probably so called from the *Mamertini*, a mercenary band of rebellious soldiers, who were defeated and almost annihilated by Hiero of Syracuse.

MAMILLA, a genus of Mollusca, of the family *Naticida*, in which the shell is heavy and oval, and the spire small and pointed.

MAMMALIA (by some writers anglicized into the term *Mammals*) is a term employed by naturalists to designate all those animals which give suck to their young.

In the Mammalia, the nervous system is concentrated in a true brain (*cerebrum* and *cerebellum*), and a spinal cord; the heart consists of two auricles and two ventricles; the blood is red and warm; the respiration is atmospheric; the lungs are free in a true chest; the jaws are furnished, as a rule, with true teeth; the limbs are usually four, sometimes two; habits arboreal, terrestrial, or more or less aquatic, and the limbs accordingly modified.

Within the class of the Mammalia the porpoises, whales, lamantins, and dugongs are included, animals essentially aquatic as far as *habitat* is concerned, but no farther. [NATURAL HISTORY.]

MAMMALOLOGY, a science having for its object the study and classification of the MAMMALIA. [ANATOMY, COMPARATIVE; ANIMAL.]

MAMMARY GLAND is an organ of considerable interest from its occurring only in that important class of animals to which it gives its name [MAMMALIA], and whose greatest peculiarity is that, while young, their food is the milk secreted by the mammary glands of their mother.

The number of mammary glands varies in different animals. They are composed of ramified ducts which open on the surface of a nipple, or teat, by a very minute orifice. In some animals, as ruminants, there is but one orifice at the extremity of each nipple; in others, and in man, there are several. Each orifice leads into a fine canal, which, however, soon dilates, and ramifies with irregular and tortuous branches in the substance of the breast or udder. Each branch has either a simple closed extremity or terminates in a minute cellule, and numerous capillary blood-vessels ramify on their walls and secrete the milk into them. When the mouth of the young animal, by the action of sucking, produces a partial vacuum over the nipple, the weight of the surrounding medium presses lightly and equally upon the surface of the breast or udder, and propels the milk from the ducts in minute and gentle streams.

At the commencement of pregnancy, the mammary gland, which up to the period of puberty had been but little developed, enlarges; its increase of size keeps pace with the progress of gestation, and before its termination a thin serous milky fluid begins to be secreted. Directly after parturition, the quantity of milk increases, and it becomes more thick and rich, combining in itself all the best principles for the nourishment of the young animal. It continues to

flow for a length of time, proportioned to the age at which the young animal can seek its own food, and then, gradually subsiding, the gland decreases to the same size which it had before pregnancy.

In males of all species only a rudiment of this organ is found; yet there are not wanting instances in which milk has been secreted from the breasts of men and other male animals. (Blumenbach.)

MAMMEA, a genus of the natural family of *Cuttiferae*, so called from the American name (*Mamey*) of *Mammea Americana*, or the American Mammee-tree, which is the only species of this genus, and forms a handsome tree with a spreading and elegant head, resembling that of a magnolia. The flowers are odoriferous. The fruit is large, and has a double rind, of which the outer is thick and leathery; the inner is thin and bitter, and contains the pulp closely adhering to it, which is of a yellow apricot colour. This pulp has a pleasant but peculiar taste, with an aromatic smell. It may be eaten raw, or cut in slices to eat with wine or sugar; or cooked, which deprives it of its gummy portion. It is also preserved in wine sweetened with sugar, or in brandy.

MAMMOTH (Russ. *mamant*, 'an animal of the earth'), the name of an extinct colossal species of elephant, nearly allied to the *Elephas Indicus* of Cuvier, but distinct from the Mastodon. The bones of this huge mammifer have been discovered in various parts of the world, and sometimes in a complete state. In the British Museum is to be seen an entire skeleton, with all the bones skilfully articulated; and in the Museum of St. Petersburg is exhibited a perfect skeleton, the carcass of which was found preserved in ice in the north of Russia towards the end of the last century. In the Museum of Philadelphia is shown a colossal specimen which was found in 1801, at Newburgh, on the Hudson River, in the State of New York, about twelve feet below the surface of a morass. In 1817 the remains of a mammoth were discovered near the town of Goshen, Orange County, within sixty miles of New York. The length of the skeleton was computed at 20 feet; but following its curvature it measured, from the point of the tusks to the end of the tail, 31 feet; the length from the chin to the rump, 15 feet; and the height over the shoulders, 11 feet. The entire skeleton weighed about 1000 lbs. The distinguished traveller and naturalist, Peter Simon Pallas, who was employed by Catharine of Russia to explore different parts of her empire, states that from the river Don to Tchutskoiness, there is scarcely a river that does not exhibit the remains of the mammoth, and that they are frequently imbedded in alluvial soil containing marine remains. Entire carcasses of the animal are seldom found; but isolated bones have frequently been discovered in different parts of the world, especially in Russia, Sweden, Siberia, Iceland, Poland, Germany, Hungary, Holland, and the north of the American continent, in Ireland and Scotland, and occasionally in the alluvial soils of England. Tusks, teeth, and bones of prodigious size have been found in the valleys of the Thames and the Medway; at Trenton, near Stafford; at Gloucester; in the county of Northampton; in Holderness, Salisbury Plain, Essex, and Norwich. They never occur in the regular strata, but in the superimposing drift. Blumenbach, writing in 1803, states that within his knowledge above two

hundred of these elephantine fossils had been found in Germany. It is, however, in the colder latitudes of Asiatic Russia that the mammoth, or fossil elephant, most extensively abounds; and there the ivory tusks are sometimes found in so perfect a state, as to be converted into articles of commerce, and used for ornamental purposes.

MAMMOTH CAVE, THE, is the largest known cavern in the world. It is situated in Edmonston County, Kentucky, and consists of a series of caverns, which have already been explored to a distance of ten miles. It formerly contained remains of fossil elephants, and has probably been the bed of a subterranean river. In fact, it still contains a stream in which two kinds of fish have been discovered—one without eyes, and the other with eyes, but blind. The equability of its temperature at one time induced many persons suffering from consumption to take up their abode in one of its caves; and a hotel was actually built, but it has long been untenanted.

MAMUN. [ABBASIDES.]

MAN constitutes the sole specific example of the only genus, *Homo*, contained in Cuvier's order *Bimana*.

The anatomy and physiology of man are treated of under their appropriate heads in this work. The present article is limited to the consideration of man as an object of natural history.

In man the attitude is erect. The skull is nearly balanced upon the vertebral column, which, though not absolutely straight, yet has its curves so arranged, that when the body is in the erect posture a vertical line drawn from its summit would fall exactly on the centre of its base. The naturally erect position of man requires an expansion of the os sacrum and haunch bones, for the lodgment of powerful muscles; and the strength and size of the lower limbs are such as not only to support with ease the weight of the body, but also to insure firm, easy, and graceful progression; the foot is broad; the leg bears vertically upon it; the heel is tumid beneath; the toes are short, the first far exceeding the rest in size, placed on the same line as the others, and not opposable to them. Man is truly bipedous and plantigrade.

The lower limbs of man being the exclusive organs of locomotion, at least on the ground, his anterior extremities are free. The arms are well developed and muscular; the humerus rotates freely in the shallow articulating cavity of the scapula; the shoulders are kept wide apart by means of well-developed clavicles; the fore-arm is capable of pronation and supination; and the hand is at once an organ of touch and prehension; the thumb is truly opposable to the fingers, which are of unequal length, for the sake of insuring easier manipulation and greater precision. No other animal has a true hand.

In man the chest is large and expanded; it is flattened in front, and has greater dimensions transversely than in depth; the sternum is short and broad; the ribs are, on each side, 7 true and 5 false, total 12. Mammæ 2, pectoral. The teeth of equal length and approximating together, without intervals:—

Incisors, $\frac{4}{4}$; Canines, short, $\frac{1-1}{1-1}$; Bicuspid Molars,

$\frac{2-2}{2-2}$; True Molars, bluntly quadricuspid, $\frac{3-3}{3-3} = 32$.

Food—fruits, grain, roots and animal flesh, cooked; as a general rule, the diet of man is prepared by cooking for the stomach. In the colder regions oleaginous animal food is preferred; rice and farinaceous food in the hotter climates; and various are the degrees between these two extremes, according to latitude and national predilections.

Growth, slow; infancy, long; maturity acquired at a comparatively late period.

Skin, smooth. Natural offensive or defensive weapons denied by nature. Everywhere man uses artificial weapons: the club, the spear, the bow, the knife, and the hatchet are the weapons of savages.

The nervous system is highly developed; the brain is large, convoluted, complex, with the cerebral hemispheres greatly preponderating. The mass of the brain is voluminous in proportion to the size of the nerves communicating with it. In consequence of the volume of the brain, the amplitude of the cranial portion greatly preponderates over the facial. Man has no projecting snout; the face is nearly on a plane with the rising forehead, and therefore below and not anterior to the brain; this position is peculiarly characteristic of man, for the crania of the chimpanzee and orang, which approach nearest to that of man, are altogether posterior to and not above the face. This form, at the same time that it remarkably distinguishes the human from the brute features, is exactly adapted to the erect attitude. In that posture the plane of the orbits is nearly horizontal; the cavities of the nose are in the best direction for inhaling odours, proceeding from before or from below them; the jaws do not project in front of the forehead and chin. But, suppose the posture changed, as painful an effort would be required to examine an object in front of the body as is now necessary to keep the eyes fixed on the zenith, and the heavens would be almost hidden from our view; the nose would be unable to perceive any other odours than those which proceeded from the earth or from the body itself; and the teeth and lips would be almost useless, for they would scarcely touch an object on the ground before the forehead and chin were in contact with it; while the view of that which they attempted to seize would be obscured by the nose and cheeks.

Man is the only animal endowed with the gift of language, as distinguished from mere sounds instinctively uttered, and expressive of feelings or desires.

Man is a true cosmopolite; he inhabits the dreary regions of the polar circle, the temperate latitudes, and the glowing countries of the tropics. He subsists with equal facility under various degrees of atmospheric pressure; the valleys and also the elevated table-lands of South America, some of which are 10,000 feet high, are alike inhabited by man—the barometer standing in the one at 30, and in the other at only 20 inches. Condamine and Bouguer with their attendants lived for three weeks at a height of 14,600 French feet above the level of the sea, where the barometer stood at only $15\frac{3}{4}$ inches, the atmospheric pressure being therefore only a little more than half of that to which they had been accustomed.

Considerable differences occur in the average stature of different races. The Bushmen, for example, of Southern Africa are mere pigmies, the Caffres of the same country are tall and athletic; the Esquimaux are stunted; the Patagonians are often seven feet in height. In all countries individuals are to be found some far below the average standard, some far exceeding it; but these are examples of accidental departure from it. In temperate climates the average stature of the male varies from five feet six inches to six feet.

The great race of man is divided into a vast number of families or varieties, distinguished from each other by physiognomy and slight structural details, by colour, by the characters of the hair, by language, by habits, manners, and customs, and by degrees of civilization. A singular morbid variety of man occurs in all countries, but perhaps most frequently in hot climates. They are termed *albinoes*, and are distinguished by the total absence of the colouring matter of the cuticle, hair, and eyes—hence their skin is of a milk-white or pinkish hue, the hair silky, white, or at most yellowish; the iris rosy, and the pupil red. Albinoes occur among our domestic quadrupeds: white rabbits and white mice are examples. [ETHNOLOGY.]

MAN, ISLE OF, is situated between $54^{\circ} 4'$ and $54^{\circ} 27'$ N. lat., and $4^{\circ} 17'$ and $4^{\circ} 48'$ W. long.; 34 miles from St. Bees' Head in Cumberland; 16 from Burrow Head in Scotland; and 28 from Strangford in Ireland. Its length N.E. to S.S.W. is about 30 miles; its breadth varies from about 8 to 11 miles, but is much narrower at its extremities; and its circumference is about 75 miles. The area is about 220 square miles, or 180,000 acres. The population in 1861 was 52,469, being an increase of 82 only since 1851. At the last census there were 8946 inhabited houses in the island, 477 uninhabited, and 93 building. The Calf of Man is a small island situated to the south-west of the island, nearly a mile from it, and from 3 to 5 miles in circumference. The Kitterlins, another small rocky island, is situated between the Isle and Calf of Man.

The island is intersected by a ridge of hills, which runs from north-east to south-west nearly through its whole length, and chiefly occupies the central parts. The hills compose three chains, separated from each other by high table-lands, and crossed by three very narrow openings. Snaefell, the highest point of them all, is 2004 feet above the level of the sea, and North Barrule rises to 1804 feet. The mountains, commons, and waste lands are supposed to cover 50,000 acres, leaving above 90,000 acres for cultivation. England, Scotland, Ireland, and Wales are visible from the summits of the mountains on a clear day. The Neb, Colby, and the Black and Gray Waters, which flow from the mountains, enter the sea at Peel, Laxey, Douglas, and Ramsey. The coast is in many places very precipitous.

Rocks of mica-slate and clay-slate compose all the mountains. A considerable quantity of roofing slate and building stone is exported from the island. Lead, zinc, iron, and copper are found in the mountainous districts. Granite and other boulders are scattered about the island.

The soil in the south part of the island is a light clay formed by the decomposition of the clay-slate.

The mountainous district is adapted only for pasture, and judicious culture alone can render the hilly parts productive. The northern part is more fertile. The climate is temperate. The agriculture of the country, in consequence of the attention paid to the herring fishery, was formerly left very much to the women, who were accustomed to perform all the hard work of a farm, and frequently without their aid the corn itself would have been unthrashed; but great improvements have been introduced in recent years. The largest part of the island is in the hands of small yeomen, who farm their own estates, which vary from 10 to 200 acres.

The early history of the Isle of Man is obscure. It was governed by a succession of Norwegian kings, until Magnus, finding himself unable to preserve the Western Isles, sold them to Alexander III., king of Scotland, in 1264. The Isle of Man soon afterwards passed into the hands of the English; and in 1307 Edward II. bestowed this island first upon the earl of Cornwall, and then on Henry Beaumont. It passed through many hands until it came to the Stanleys, earls of Derby, who retained the title of Lords of Man. James, earl of Derby, embraced the cause of Charles I. in the civil war, was taken prisoner, and executed at Bolton in 1651. His wife, who figures conspicuously in Sir Walter Scott's novel of 'Peveril of the Peak,' was as obstinate a royalist as her husband. She threw herself into Castle Rushin, and maintained a vigorous resistance, until Christian, who commanded the insular troops, surrendered to the Parliamentary forces under Birch and Dukinfield, stipulating that the islanders should enjoy their rights and liberties. For this act his memory has been burdened with much unjust obloquy. The earls of Derby retained the lordship until 1736, when it passed to the dukes of Athole, who eventually disposed of their rights and patrimony to the crown for a sum of 416,000*l*.

The natives are a Celtic race, and speak a language known as the Manx, which, however, is rapidly becoming obsolete. They retain a plentiful store of those fantastic legends which overawed the reason of a credulous age, and excite the curiosity of our own. Some of the Manx ballads possess an historical importance.

No part of the kingdom possesses more valuable Danish remains. The various tumuli, barrows, weapons, coins, and Runic characters afford clear evidence of the connection which the Northmen had with this island. Rushin Abbey, St. Bridget's Abbey, and the tumulus of Tynwald are among the most interesting relics of antiquity.

The principal towns in the island are Castletown, Douglas, Peel, and Ramsey.

Castletown is situated on the south-west of the island; it is a neat town, with regular streets. It contains two or three chapels, and a well-conducted college. The remains of Castle Rushin are in this town. The population in 1861 was 2692. The courts of chancery and common law are held in Castletown, and it is the residence of the governor. The House of Keys meet here.

Douglas is situated on the south-east coast of the island, on a bay which extends three miles in the form of a crescent, and is sheltered from all winds except the south-east. The old streets are generally

very irregular, but some modern streets are regularly built. Castle Mona, built by the duke of Athole, and a number of good mansions, give a pleasant appearance to this town. Paper, linen, and woollen manufactures are carried on. The population in 1861 was 12,511. There is a pier 520 feet long.

Peel, formerly called *Holm Peel*, *Pile Town*, or *Sodor*, is on the west coast of the island. The castle, which is built on a small rocky island, incloses an irregular space of more than two acres, and is separated from the town by a narrow channel, scarcely a foot deep at low water. Peel has only one church. The population is 2848.

Ramsey is situated on a spacious bay, where there is safe anchorage, on the north-eastern coast of the island. It is built in a straggling and irregular manner. In this town the courts of law for the north part of the island are held. Population, 2890.

The herring fishery is one of the chief occupations of the people. Steam communication is maintained with the three kingdoms.

The established religion is that of the Church of England, but all denominations of Christians have the free exercise of their religion. The episcopal see is supposed to have been fixed at Sodor in the ninth century, but the site of this place is not now known. The bishop of Sodor and Man, whose authority is wholly confined to this island, is a suffragan of the archbishop of York, and has a seat in the House of Lords, but without a vote. He has an archdeacon and his assistant, two vicars-general, and an episcopal registrar; and he holds also an ecclesiastical court, a convocation, and a consistorial court.

All the laws of the island are contained in one small volume. There are no barristers, and the services of the attorneys, who act both as attorneys and barristers, are in many cases rendered unnecessary by the clients pleading their own causes. Law is cheap, and litigation common.

The House of Keys, which has both a legislative and judicial character, consists of twenty-four of the principal commoners of the island. They must have landed property, and have attained the age of twenty-one. They are now a self-elected body, but were formerly chosen by the people. The two deemsters have equal jurisdiction, and are judges in civil and criminal cases. There are a court of chancery, a court of exchequer, and six common-law courts. In these latter, all disputes about land, and all personal actions for the recovery of damages, are tried before a jury. The deemsters administer the oath in the Manx language, deliver the charge, and receive the verdict. There is an appeal from the judgment of a court of common law, first to the House of Keys, afterwards to the governor, and finally to the privy council. A reform in the peculiar constitution and legislation of the island seems urgently called for, and is, at present, in contemplation.

Schools, both in the English and the Manx tongues, have been established in various parts of the island.

The public revenue derived from the Isle of Man has for many years been almost 20,000*l*. per annum less than the expenditure; and as the customs duties were unusually light as compared with other parts of Great Britain, in 1866 an Act was passed to raise them so far as to obtain a revenue sufficient for the expenses of the island.

The total number of vessels which entered the three ports in the Isle of Man in 1865 was 1560 (125,154 tons), and the clearances 835 (82,692 tons). The customs revenue received in the same year was 34,178*l.*, the amount being distributed amongst the different ports as follows:—Castletown, 3688*l.*; Douglas, 25,347*l.*; and Ramsey, 5143*l.*

(Waldron's *Description of the Isle of Man*; Townley's *Journal in the Isle of Man*; Feltham's *Tour through the Isle of Man*; Wood's *Account of the Isle of Man*; *Parliamentary Papers*; Dendy's *Islets of Britain, &c.*)

MANAKINS, the name of a group of small birds remarkable for the rich tints of their plumage (*Pipra* of authors).

MANATIDÆ. A family of animals belonging to the class *Mammalia*, order *Cetacea*, sub-order *Sirenia*. The genus *Manatus*, lamantin or sea cow, is characterized by two small upper acute incisor teeth when young. These disappear in adults, in which also the canine teeth are wanting. The

dental formula of the molars is $\begin{smallmatrix} 8-8 \\ 8-8 \end{smallmatrix}$, with crown

square, divided by a transverse groove. The Manatees are vegetable feeders. Three genera belong to the family—*Manatus*, *Halicore*, and *Rhytina*. Of the three species of Manatees, one is met with on the African coast (*M. senegalensis*), and two on the American coast (*M. latirostris* and *M. australis*). Their flesh is said to be good, and is eagerly sought after. The full-grown forms vary from six to fifteen feet in length. They are noted, like most of this order, for their great attachment to their young.

The *Halicore*, or Dugong, occurs on the shores of the Indian Ocean, and on the east coast of Africa. The upper jaw of the Dugong is bent forward, falls down in front of the lower jaw, and is terminated by two large incisor teeth. Like the Manatee, the Dugong is a vegetable feeder and gregarious. The *Rhytina* was represented by the single species *R. Stelleri*, or Northern Dugong, which has become extinct—the last having been killed, it is said, in 1768.

MANCHA, LA. [CASTILLA-LA-NUEVA.]

MANCHE, LA, a department in France, consisting of the peninsula of Cotentin and the district of Avranchin, parts of the former province of Normandy, is bounded S. by the departments of Ille-et-Vilaine and Mayenne, E. by those of Orne and Calvados, N.E., N., and W., by the English Channel, which is called in French La-Manche, whence the department takes its name. Its greatest length from N. to S. is about 90 miles; its average width is about 27 miles. The area is 2292 square miles, and the population in 1861 was 591,421.

Rivers, &c.—The department is traversed from S. to N. by hills of no great elevation, which branch off from the Armoric chain, and terminate northwards in Cape La-Hague. These hills slope down gradually towards the coast on the eastern and western sides of Cotentin, in some places presenting bold cliffs against the sea, in others subsiding into sands and beaches of vast extent, which are always covered at full tide. Along the coast there are several harbours and roadsteads, the most important of which are—Cherbourg, La-Hogue, Granville, Regneville, Carteret, &c. Among the numerous islands that stand in near the coast, besides the Channel Islands, are—Mont-

St.-Michel, the CHAUSSEY group, Pelée, N.E. of Cherbourg; and Tatihou and St. Marcouf, on the east coast of Cotentin. Most of these islands are fortified and garrisoned; many of them, traditions say, were once joined to the mainland. From the nature of the surface the rivers must be all of short course: the principal are the Vire [CALVADOS]; the Taute, Merderet, Douve, and Selune, all navigable. Capes La Hague and La Hogue, and Point Barfleur, are on the coast. The climate is mild but moist, and too cold for the cultivation of the vine.

Products, &c.—The department yields more of bread-stuffs than suffices for the consumption. Wheat, barley, rye, buck-wheat, black oats (cakes made of which form the chief food of the labouring class), and potatoes are the chief crops. Apple and pear trees are extensively cultivated for making cider and perry, the favourite beverages of the country. Of cider, 44,000,000 gallons are made annually; some of it, especially that made near Avranches, is of excellent quality. Hemp and flax are grown in considerable quantity on the eastern slopes of Cotentin. Fruits of various kinds are sedulously cultivated in the arrondissement of Avranches. Horses of the true Norman breed are numerous, and yield the breeder good prices; they are much sought after as cavalry horses, and are said to be the best in France. The pastures are good and extensive, affording food for a great number of horned cattle of large size and excellent fattening qualities. A considerable number of sheep are fed on the sandy plains (locally called *mielles*) which extend between the sea and the cultivated land; they are small, yield inferior wool, and have sweet flesh. Game, water-fowl, and fish of all kinds are abundant.

The department is rich in minerals. Iron, lead, and coal mines are worked; granite and building stone are quarried; marble, slate, potter's clay, and limestone are found. Mineral springs are numerous; there are a few salt marshes along the coast.

Manufactures, &c.—Manufacturing industry is actively exerted in the making of iron, the working of zinc and copper, the fabrication of plate glass, serge, calico, drugget, cutlery, woollen stuffs, lace, tape, haircloth, linens, porcelain, oil, hardware, cotton yarn, paper, leather, soda made from kelp, basket-work, &c. Shipbuilding is actively carried on at Cherbourg and other towns on the coast. The articles enumerated and the products of the soil support an active commerce and coasting trade.

Divisions, Chief Towns, &c.—The department contains 1,467,308 acres, and is divided into six arrondissements, which, with their subdivisions and population, are as follows:—

Arronds.	Cantons.	Communes.	Pop. in 1861.
St.-Lô, . .	9	117	94,855
Coutances, .	10	138	123,032
Valognes, .	7	118	86,044
Cherbourg, .	5	73	98,606
Avranches, .	9	124	116,488
Mortain, . .	8	74	72,396
Total, . .	48	644	591,421

In the arrondissement of St.-Lô, the chief town is St.-Lô. [Lô, St.] *Carentan*, a town of 3110

inhabitants, is situated near the coast among unhealthy marshes on the left bank of the Taute. It was formerly defended by a strong castle, a great part of which remains; this castle was taken by Edward III. in 1346. *Percy*, S.W. of St.-Lô, has a population of 3003. *Torigny*, S. of St.-Lô, a small well-built town of 2082 inhabitants, is famous for its ancient castle, which before the Revolution of 1789 was considered the finest building of the kind in Normandy.

In the arrondissement of Coutances, the chief town, *Coutances*, the capital of the old district of Cotentin, is situated at the confluence of the Soule and the Bulsard, 8 miles from the English Channel, and 41 from Cherbourg. It is in general ill built, with narrow crooked streets, but the situation is very picturesque. The town is said to have existed in Roman times, and to have taken its name from Constantius Chlorus, who fortified it and built the aqueduct now called *Les Piliers*, from the Roman arches of it still remaining. The principal buildings are the cathedral, which is universally admired, the churches of St.-Nicholas and St.-Pierre, the prison, and the theatre. Coutances has a prefecture and public library; it gives title to a bishop, and has communal and theological colleges, and 8062 inhabitants. The industrial products are cutlery, parchment, druggist, muslin, worsted, lace, &c.; the chief trade is in corn, butter, poultry, eggs, cattle, horses, hempen and flaxen thread, wool, feathers, &c. *Cerisy-la-Salle*, 7 miles from Coutances, has a population of 2017; there are several druidical monuments near it. *Gavray*, famous for its long resistance to Duguesclin, stands 12 miles S. by E. from Coutances, and has 1821 inhabitants. *Périers*, N. of Coutances, has a population of 2794.

The arrondissement of Valognes is named from its chief town, *Valognes*, which stands in a pretty valley 11 miles S. by E. from Cherbourg, and has a tribunal of first instance, a college, and 5812 inhabitants, who manufacture hats, lace, and gloves. The principal building is that in which the college and public library are established, and which was formerly a theological seminary. *Barfleur*, an important seaport in the time of the Norman kings of England, and from which it is said that William the Conqueror set out for the conquest of England, stands on the eastern shore of the peninsula of Cotentin; it is now a mere fishing village with 1304 inhabitants, and has a harbour capable of admitting only small craft; about a mile to the N. is a lighthouse, 271 feet above the sea, on Cape Barfleur. Prince William, only son of Henry I., with a retinue of young nobles, sailed from Barfleur in the *White Ship* (La Blanche Nef), which was stranded on a rock soon after leaving the harbour, and only a butcher of Rouen regained the shore. *Briquebec*, situated in a forest of the same name W. of Valognes, has a handsome church, an ancient ruined castle, and 3905 inhabitants. There are several iron mines and mineral springs near this town. North-east of Valognes on the eastern coast of Cotentin is the fortress of *La-Hogue*, which is built on the isthmus of a peninsula terminating in Cape La-Hogue, and defends the roadstead of La-Hogue. Off the cape on the 29th of May, 1692, the French fleet, under Admiral Tourville, was completely defeated by the

combined fleets of England and Holland, under Admiral Russell. *Montebourg*, S.E. of Valognes, has 2214 inhabitants, who manufacture lace, cutlery, and leather. *Sainte-Mère-Eglise*, S. of Montebourg, on the road to Carentan, has a population of 1575. *St.-Sauveur-le-Vicomte*, a well-built town prettily situated on an eminence above the Douve, has 2722 inhabitants.

In the arrondissement of Cherbourg the chief town is CHERBOURG. *St.-Pierre-Eglise*, a small town E. of Cherbourg, has 2265 inhabitants, who manufacture linen and leather. *Les-Pieux*, a small place built on a hill near the west coast of Cotentin, is remarkable for the extensive view from it, in which are included the islands of Guernsey and Jersey, and twenty churches on the peninsula. Population, 1526.

Of the arrondissement of Avranches the chief town is AVRANCHES. *Brécéy*, E. of Avranches, has 2440 inhabitants. *Granville*, a seaport and walled town N.W. of Avranches, having the island of Jersey in sight, has a tribunal of commerce, a naval school, and 17,180 inhabitants. The town stands on a rocky promontory projecting into the English Channel, 30 miles S.W. of St.-Lô. The principal public buildings are the parish church, custom-house, granite mole, inclosing a harbour, citadel, hospital, and public baths. The inhabitants of Granville are enterprising seamen, and are largely engaged in the coasting trade and in the cod, herring, whale, and oyster fisheries. They export corn, flour, butter, cider, poultry, cattle, granite blocks, &c., and import wine, brandy, colonial produce, drugs, salt, hemp, soap, oak and deal planks, iron, &c. Ship-building is carried on. Granville is the seat of a tribunal of commerce, has a school of navigation, and is the residence of a commissary of marine. It was destroyed by the English in 1695, and besieged by the Vendéans in 1793. On the isolated and fortified rock of *Mont-St.-Michel*, stands the famous abbey dedicated to St. Michael the Archangel. The abbey buildings, after the first French Revolution, were made a prison for nobles and priests; it afterwards became a central prison for several departments, and was restored in 1864. The abbey church, which springs from the centre of the other buildings, and crowns the summit of the rock, is greatly admired for the beauty of its Gothic architecture. *St.-James*, S. of Avranches, has a population of 3270, who trade in corn, cattle, flax, and hemp. This place was fortified by William the Conqueror. *Villedieu*, N.E. of Avranches, has 3789 inhabitants, who manufacture hardware and plated goods, lace, and leather.

The arrondissement of Mortain is named from its chief town, *Mortain*, which is situated in the south-east of the department, and has linen manufactures, and 2490 inhabitants. The church of Mortain, founded in 1082, is a remarkable structure; the castle that formerly stood on the hill above the town is a heap of ruins. *Barenton*, S.E. of Mortain, has a population of 2818. *St.-Hilaire-du-Harcourt*, near the confines of Normandie, Bretagne, and Maine, has large markets for the sale of the cattle, corn, and other produce of these provinces; population, 4080. *Sourdeval-la-Barre*, N. of Mortain, has several paper mills, manufactures of cutlery and hardware, and a population of 4056. *Le-Teilleul*, on the borders

of Mayenne, 9 miles S. from Mortain, has 2478 inhabitants.

The department forms the see of the bishop of Coutances; is included in the jurisdiction of the Cour Impériale and University Academy of Caen; and belongs to the sixteenth Military Division, of which Rouen is head-quarters. It returns four deputies to the Corps Legislatif. (*Dictionnaire de la France; Annuaire pour l'An 1866.*)

MANCHESTER, the largest manufacturing city in the world, is situated in the south-east of Lancashire on the river Irwell, which separates it from the borough of Salford. It is 168 miles N.W. by N. from London by the old coach roads, but 188 miles by the London and North-Western Railway. The parish of Manchester is of great extent, and includes numerous townships. Both the city and all the adjacent townships, as well as the borough of Salford, have increased with great rapidity during the present century, and now form the wealthiest and most populous manufacturing community in the British dominions. In 1801 the parish of Manchester contained 112,300 inhabitants; in 1851 the number had advanced to 452,258; and in 1861, the population had still further increased, and amounted to 529,245. The population of the city proper, within the parliamentary limits, in 1861, was 357,979, as against 316,213 in 1851; and of the municipality in 1861, 338,722, as against 303,382 in 1851. According to a return laid before Parliament, the population of the parliamentary city in 1866 amounted to 380,887. Manchester was made a borough by the Reform Act of 1832; a charter of incorporation was granted to it in 1838, since which several Acts for its improvement have been passed; and in 1853 it was made a city. The number of voters in the parliamentary register in 1866 was 21,542. For municipal purposes it is divided into fifteen wards, and is governed by a mayor, who is returning officer, sixteen aldermen, and forty-eight councillors.

The De Gresleys were the original Barons of Manchester; and it was from Thomas de Gresley or de Grelle, one of the barons, that Manchester obtained its governing charter in the year 1304. Many years previously King Henry II. had granted to the De Gresleys the right of holding markets and fairs at Manchester. From the time of Thomas de Grelle's charter to that of the Municipal Reform Bill of our own times, Manchester was governed by a borough reeve elected by the inhabitants, not by a mayor and corporation; and it was not until the Parliamentary Reform Bill of 1832 that this great, wealthy, and populous city received the right of returning members to Parliament.

Manchester is remarkably rich in foundations for the teaching of religion and sound learning. So early as the year 1422, Thomas de la Warr, the last baron of Manchester of that name, having succeeded to the honours and the inheritance of the De Gresleys, founded at Manchester a College, consisting of a warden and eight fellows (of whom two were parish priests), and of two canons, four deacons, two clerks, and six choristers. The cost of erecting the college was 2000*l.*, equal to from 30,000*l.* to 50,000*l.* of the money of present times. The foundation of the college was soon followed by the erection of the

Collegiate Church, or Christ's Church, now the Cathedral. The questionable honour of a right of sanctuary was afterwards conferred on Manchester; but this was soon found to be an intolerable nuisance, and was abolished at the petition of the inhabitants by a special Act of Parliament. The preamble of the Act abolishing the right of sanctuary at Manchester shows how much progress the place had made even in the reign of Henry VIII. The preamble states that the town of Manchester is well inhabited, and distinguished for its trade both in linens and in woollens; that the inhabitants have obtained rich and wealthy livings, and employ many artificers and poor people; and that by 'their strict and true dealings' they have given rise to the resort of many strangers from Ireland and elsewhere with linen yarns, wool, and other necessary wares, for making of cloth to be sold there. The preamble then proceeds to state that in the course of the manufacture of linen the flax and yarn have to lie out in the fields night and day for half a year, to be whitened or bleached, before they can be made into cloth; and that the woollen cloth made in the town and neighbourhood must also hang on the tenters to be dried before it can be dressed. It further states that Manchester, besides being the principal place for manufacturing linens and woollens, is also frequented by the manufacturers of the neighbouring towns and villages to bring goods to be finished and sold. 'Many strangers,' says the same preamble, 'inhabiting other townships and places have used customarily to resort to the said town with a great number of cottons to be altered and sold by the inhabitants, whereby many poor people have been well set to work, as well with dressing and frizzing of the said cottons, as with putting to sale the same.' 'All these persons,' says the preamble of the Act, 'are endangered by the resort of light and evil-disposed persons to the town.' For these and other reasons, it was proposed and enacted that the right of sanctuary should be taken away from the Collegiate Church of Manchester, and be transferred to Chester, where there was no such occupying of merchandise. Such was Manchester in the reign of Henry VIII. and of Elizabeth. It was already an industrious and flourishing manufacturing town, where the woollen and linen trades were carried on with spirit and success; a place much frequented by strangers for the purposes of trade, and the trading capital of all the adjoining districts, as it is to this day. The first Manchester manufacturer of great note was Byron, one of the three famous clothiers of England. About eighty years after his time arose Humphry Chetham, a most successful manufacturer, who nobly employed his great wealth in founding a college and library at Manchester. In the year 1638 Manchester contended with York for the honour of becoming the seat of a university which it was then proposed to found in the north of England. In a memorial numerously signed by the nobility, gentry, clergy, and freeholders, and other inhabitants of the northern parts of England, it is stated that Manchester 'is about the centre of the northern parts; a town of great antiquity; formerly both a city and a sanctuary, and now of great fame and ability by the happy traffic of its inhabitants; for its situation, provision of food, fuel, and buildings, as happy as any town in

the northern parts of the kingdom.' About the same time, Lewis Roberts, in his 'Tressory of Traffic,' says:—'The town of Manchester, in Lancashire, must be herein remembered, and worthily, for their encouragement, commended; who buy the yarn of the Irish in great quantity, and weaving it, return it again into Ireland to sell. Neither doth their industry rest there, for they buy cotton wool in London that comes first from Cyprus and Smyrna; and at home work the same, and perfect it into fustians, vermillions, dimities, and other such stuffs, and then return to London, where the same is vended and sold, and not seldom sent into foreign parts, who have means at far easier terms to provide themselves of the same materials.' Forty years later, Andrew Yarranton, an able writer on trade, in urging the establishment of the tape and thread manufacture in Warwickshire, says 'that if they once fix well in that manufacture there, they will become the great masters of it, as Manchester is of all things it trades in.'

In the great Civil War, Manchester adopted the side of the Parliament very early, and with great determination, and twice repulsed the royalist forces under James, earl of Derby, the lord-lieutenant of the county of Lancaster, who had laid siege to the place. It afterwards, however, became excessively dissatisfied with the rule of Cromwell and the army, and was only kept in subjection by a powerful garrison. The partizans of the house of Stuart in later times became very powerful at Manchester, especially amongst the clergy and the numerous Roman Catholics in and around the city; and this continued to be the case to the rebellion of 1745, when the Pretender obtained some adherents at Manchester.

Until about the year 1730 Manchester did not possess the advantage of water carriage with any other part of the county of Lancaster. The river Irwell is not naturally navigable either to the sea or above the city; but in the year 1731 an Act was obtained for the purpose of rendering it so, from Manchester to the point where it joins the Mersey, and of rendering the Mersey also navigable to the tidewater of the estuary at Warrington, and thus to the port of Liverpool and the sea. This was the first great improvement in the means of communication between Manchester and distant parts. A much greater one was effected between the years 1758 and 1777, when Francis, duke of Bridgewater, constructed his celebrated canals. The first of these extended from the duke's coal mines at Worsley, about 7 miles distant, to Manchester, crossing the Irwell at Barton by an aqueduct which was then considered the greatest work of the kind that existed in England. The second and much more important canal, constructed by the genius of Brindley supported by the wealth of the duke of Bridgewater, was one joining that from Worsley, at a short distance from Altringham, and extending to the estuary of the Mersey at Runcorn, a distance of about 25 miles. By means of this canal the merchants and traders of Manchester obtained a cheap and easy communication with the port of Liverpool and the sea, available at all tides. Subsequently the Manchester and Warrington Canal was greatly improved, extended to Runcorn, and, as the Mersey and Irwell Navigation, became one of the most useful

lines of internal communication in the kingdom. These two canals now belong to the Bridgewater Trust, and notwithstanding the introduction of railways, still afford the means of carrying on the greater portion of the trade between Liverpool and Manchester. In the year 1830 Manchester obtained the advantage of the railway system, and in that respect took the lead of all the manufacturing towns in the kingdom. This additional means of communication has extended with such great rapidity, that it is now the central point of a perfect network of lines.

In addition to the great facilities for trade just described, the modern progress of the manufactures of Manchester owes much of its rapidity to the invention of the steam engine, and the introduction of steam power into the cotton and other trades. Two great beds of coal of extraordinary richness almost encircle the city, and no doubt extend under it, though at a considerable depth. These have been worked with great energy and success, especially on the Pendleton side, where mines have been sunk to the depth of from 1500 to 1800 feet, which yield large supplies of coal suited for manufacturing purposes. Manchester is therefore as well suited for carrying on manufactures that depend on steam as it formerly was for those then depending on water power. Hence the progress of modern invention, instead of arresting its prosperity, has given it a wonderful impulse, the limits of which it is impossible to anticipate. The principal manufacture of Manchester is that of cotton, which has now existed there for nearly 250 years—the Levant cotton having been worked into fustians and velvets as early as the commencement of the seventeenth century. Calicoes were first made in 1772, and muslins in 1781. At present every description of cotton goods is manufactured; and nine-tenths of the raw material, of which nearly 1,000,000,000 lbs. were imported into this country in 1865, chiefly through Liverpool, are consumed in Manchester, or within twenty miles of it.

In addition to the cotton manufacture that of silk is also very extensively carried on at Manchester. This trade was introduced in 1819–20. The manufacture of machinery of all kinds has also become a great source of employment in the town and neighbourhood. There are at present (1866) about 100 cotton, 20 silk, and 20 smallware mills; 40 dye works, 50 iron foundries, and 80 large machinists' shops. There are employed in the cotton mills about 60,000 persons, who earn about 30,000l. per week in wages. There are, at least, 9000 skilled mechanics constantly engaged in the production of steam-engines, spinning mules, looms, and other machinery, chiefly for the production of the various textile fabrics, whose wages average about 28s. each per week, and who need some 2000 labourers to assist them.

The factories of Manchester are simply huge piles of brick, studded with multitudinous windows, yet remarkable, generally, for cleanliness, ventilation, regulated temperature and orderly economy.

The city of Manchester, originally built, like nearly all the cities and towns of England, with narrow crooked streets, has been almost entirely rebuilt and reconstructed during the last fifty years, and now

possesses many of the widest and best streets in the kingdom. Numerous warehouses, many of them quite palatial structures of extraordinary size, well calculated for carrying on business on a most extensive scale, have been constructed in the best business streets. During the same period the introduction of railways and omnibuses has in a great measure changed the habits of the more prosperous part of the inhabitants of Manchester, as well as of other towns, and instead of residing in squares and streets within the city as in former times, they now live in elegant villas in the neighbouring country. Almost innumerable residences of this description have been erected during the last twenty years in the most beautiful parts of the environs of the city.

Amongst the most celebrated buildings in the city are the Cathedral and the Exchange. The first-named is a very handsome Perpendicular building, originally built in 1422, and has become a cathedral only since Manchester was made the see of a bishop. It consists of a nave and aisles, and is rendered conspicuous by its lofty tower, 120 feet in height. The interior presents a striking *coup d'œil*, the roof being finely carved, moulded, and gilded, and the choir containing some admirable carved work. The Exchange, though a tolerably large and handsome building, has become quite unequal to accommodate the trade of the city, and is about to be superseded by a much larger and handsomer building, to be constructed under the powers of an Act of Parliament passed in the session of 1866.

Other public edifices worthy of notice are the Town Hall, erected on the model of the temple of Erectheus, at Athens; the Royal Institution, an edifice of the Ionic order; the Free Trade Hall, built in the Lombardo-Venetian style, to commemorate the success of the free-trade movement, large enough to hold 7000 persons; the Theatre Royal; the splendid New Assize Courts, in decorated Gothic, the best building of the kind in the kingdom; the Chetham College Blue Coat School, founded 1651; Bishop Oldham's Grammar-school, founded 1520, endowed with twelve scholarships; Owen's College in Quay Street; with ten professorships attached; Lancashire Independent College, at Withington; Wesleyan Theological Institution, at Didsbury; Royal Infirmary and Dispensary, founded 1753, with statues of Wellington, Sir R. Peel, and Dr. Dalton; School for Deaf and Dumb, and Henshaw's Blind Asylum, at Stretford; School for Infant Deaf and Dumb, at Old Trafford; Industrial School, at Swinton, in the Tudor style; and the New City Gaol. There are in the boroughs of Salford and Manchester altogether about seventy churches belonging to the establishment; ten Roman Catholic, and upwards of one hundred Dissenting chapels, some of which, such as the Catholic Cathedral and the Cavendish Independent Chapel, are very beautiful specimens of architecture. There are also two Jewish synagogues, two German and a Greek church. The more noticeable churches are—St. Ann's and St. Paul's, handsome Grecian structures; St. John's, in the later English style; St. Matthew's, designed by the late Sir Charles Barry; and in Salford, Trinity Church—a good specimen of Perpendicular—and St. Simon's, an Early English edifice with a tower and spire 153 feet high.

Among the educational establishments in Man-

chester, perhaps the most remarkable is the celebrated Free School for 350 boys, which was established in 1854 in order to prove that the children of every sect could be advantageously taught together. It has since been sustained by voluntary subscriptions for the benefit of children whose parents are utterly unable to afford them any education, and is generally considered to have proved thoroughly successful in its aim.

Manchester was the first borough to take advantage of the Free Libraries Act, which allows a local assessment of a penny in the pound for libraries and museums. It now possesses four free public libraries, containing nearly 100,000 volumes, of which over 2000 are changed daily. In the town-hall is the corporation library, an exceedingly valuable collection of books, parliamentary papers, &c. The Mechanics' Institution and the Athenæum are large handsome buildings, each having an excellent library.

There are several private banks and also branches of the Bank of England, and National Provincial Bank of England. Two daily and several weekly papers are published. This city is amply supplied with water from extensive reservoirs constructed in the valley of the river Etherow, and along its course for about 5 miles, and conveyed thence in large pipes a distance of about 17 miles. These works are perhaps the most extensive of the kind in Europe. Altogether about 1,500,000*l.* have been invested in them. They as well as the gas-works and the market and manorial rights, which have cost 700,000*l.*, belong to the corporation, who devote the immense profits accruing from them to city improvements.

In the year 1846 some spirited inhabitants determined to provide several public parks for the accommodation of the people. A very large subscription was entered into for this purpose, and three parks, named the Queen's, the Peel, from the late Sir Robert Peel, who was one of the warmest and most liberal supporters of the plan, and the Phillip's Park, were constructed in the townships of Salford, Bradford, and Harpurhey. Victoria Park, to the south of Manchester, has handsome villas around it. Botanical and zoological gardens have also been laid out in the vicinity of the city, and there are several extensive cemeteries in which much taste has been displayed.

The diocese comprises the archdeaconries of Manchester and Lancaster. It was so constituted in 1848, but the title of a city was not conferred till 1853, prior to which the Cathedral was a Collegiate Church. The bishop's income is 4200*l.*; and his seat is at Mauldeth Hall, near Manchester. He has the patronage of thirty-six livings (most of them alternate with the Crown). The dean's income is 2000*l.* The dean and chapter have the patronage of eighteen livings.

Manchester was the first inland place in England that obtained the privilege of warehousing in bond articles liable to customs duties. The amount of public revenue derived from this source in 1865, was 128,458*l.*

The city of Manchester is a place of great antiquity: having existed from the time of the Roman occupation of Britain, when it was called Mancunium, evidently from the name which it bore as a settlement of the Brigantes, *Mancenion*. It was a borough in the time of the Anglo-Saxon kings. The conversion

of its inhabitants is said to have been accomplished by St. Paulinus about 627. It was occupied by the Danes in the ninth century, but they were expelled in 920 by Edward, king of Mercia. It began to be a manufacturing town in the reigns of Edward I. and Edward II., and was the most active inland trading place in the north of England in the reign of Henry VIII. Manchester cotton is spoken of as early as 1352, but the fabric so designated was really a coarse woollen cloth. At that time, and considerably later, the woollen manufacture was the principal branch of industry carried on. For this it was admirably suited, owing to the abundant supplies of water and of water-power furnished by the three rivers, the Irwell, the Irk, and the Medlock, which unite at or flow through the city, and which bring together at that point a greater amount of water-power than is to be found at any other place in Lancashire. Soon after the woollen manufacture had been established, that of linen was introduced, the chief supplies of yarn being obtained from Ireland, by way of Liverpool. Somewhat later the cotton manufacture was commenced, which gradually took the lead of all the rest.

MANCHESTER, a city of New Hampshire, United States of America, is pleasantly situated on the east bank of the river Merrimac, at the falls of Amoskeag, 18 miles S. of Concord, 59 miles N.W. of Boston. The town is laid out in broad elm-shaded streets, with five spacious public squares. A considerable trade is carried on in manufacturing cotton, prints, starch, paper, and locomotives. There are fourteen churches and seven banks. Population in 1866, 24,000. The Falls, or Rapids, which descend 50 feet in a mile, are economized by numerous factories.

MANCHINEEL TREE. [HIPPOMANE.]

MANCHOORIA, an extensive but comparatively unknown district of China, which comprises all the easternmost portion of the great Asiatic central tableland, from lat. $41^{\circ} 30'$ to 56° N., to long. $116^{\circ} 30'$ to $141^{\circ} 15'$ E. The Yablounoi mountains, which separate it from the Russian government of Yakutsk, form its northern boundary; on the E. it is bounded by the Sea of Okhotsk, the Sea of Japan, and the Gulf of Tartary; on the S. by Corea and the Gulf of Pe-che-lu; and on the W. by Mongolia and the Russian government of Irkutsk. Its area is estimated at 700,000 square miles, and its coast-line extends about 1200 statute miles. Though forming on the whole a tableland of great elevation, its surface is relieved by several important mountain chains, of which the Yablounoi, as already described, bounds it on the north, and the Khirgan mountains in the west traverse it from north to south. These mountains are densely covered with vast forests of pine, which afford asylum to numerous kinds of wild beasts, while in the warmer localities flourish several varieties of the rose and the azalea, besides buckthorns and honeysuckles. The climate in the south is by no means severe, and the soil is generally fertile; but in the north a Siberian rigour prevails, and the inhabitants are compelled to maintain themselves by the chase.

Manchooria is divided into the three provinces of Shing-king, south; Kirin, east of the river Songari; and Tsi-tsi-har in the west. The chief town is Moukden, lat. $41^{\circ} 53' 30''$ N., long. $123^{\circ} 7'$ E. The principal river is the Amoor or Sagalin, which flows into the Gulf of Sagalin, in long. 140° E.,

and receives the tributary waters of the Songari, the Oussuri, the Thiukiri, and the Silimpti. There are three considerable lakes—the Hurur, 200 miles in circuit; the Kiuka, 50 miles long and 25 miles broad; and the Pir.

The Manchos are a Tungusian race. They invaded China in the seventeenth century, and placed their leader's son on the throne of the Celestial Empire, which is still possessed by the Manchoo dynasty. Population, about 4,000,000.

MANCIPIUM, in Roman law, signifies the right of property and of dominion which only Roman citizens could enjoy over their children, slaves, lands, and animals tamed for the service of man. The same word is used to designate the nature, character, and form of the sale by which such property could be transferred. It could take place only between Roman citizens, required the presence of five witnesses and a balance holder (*libripens*), and the use of certain prescribed formulæ. The property which formed the subjects of mancipium was *res mancipi*, and consisted of such things as would naturally form the wealth of an early agricultural people. All other things were *res non mancipi* and property in these passed by mere *traditio* or delivery. The distinction between *res mancipi* and *non mancipi* was abolished by Justinian.

MANDAMUS (Lat. 'we enjoin'), is a writ by which the Court of Queen's Bench, in the name of the reigning sovereign, commands the party to whom it is addressed to do some act in the performance of which the prosecutor, or person who applies for or sues out the writ, has a legal interest, that is, not merely such an interest as would be recognized in a court of equity or in a court of ecclesiastical jurisdiction, but an interest cognizable in a court of common law; the right must also be one for the enforcing of which the prosecutor has no other specific legal remedy. Thus, a copyholder can transfer or alien his customary tenement or estate in no other manner than by surrendering it into the hands of the lord of the manor to the use of the purchaser or surrenderee. The courts of common law formerly took no notice of the right of the surrenderee to call upon the lord for a grant or admittance, and the Court of Queen's Bench therefore left the party to seek his remedy in a court of equity, and would not interfere by granting a mandamus. But the obligation on the part of the lord to admit the surrenderee is not merely an equitable liability, because this mode of transferring property of this nature is founded upon ancient custom, and rights dependent upon custom are matters of common law cognizance. Of late years the Court of Queen's Bench appears to have taken this view of the subject, and has awarded writs of mandamus in all cases where the lord has refused to admit the party to whose use a surrender of the copyhold has been made.

The term 'mandamus' (we enjoin) is found in a great variety of writs, and those usually distinguished by this name by the old law writers are totally different from the modern writ of mandamus, which appears to be nothing more than the ancient 'writ of restitution' enlarged to embrace a great variety of objects, that writ being adapted merely to the purpose of restoring a party to an office from which he has been unjustly removed.

The writ of mandamus is now granted not only to restore a man to an office from which he has been wrongfully removed, but also to admit to an office to which he has been duly elected or appointed.

In order to obtain a mandamus, the applicant lays before the court the affidavit of himself or of others, presenting the facts upon which his right and interest in the thing to be done, and his claim or title to the remedy, are founded. Upon this application, the court can grant a rule calling upon the party against whom the writ is prayed to show cause why such writ should not be awarded. At the appointed time the party so called upon either does not appear, in which case the rule is made absolute, and the mandamus is awarded as prayed, or he appears and resists the rule, either by insisting upon the insufficiency of the facts disclosed by the affidavits upon which the rule was obtained, or by producing other affidavits which give a different aspect to the transaction. If the resistance be effectual, the rule is discharged; if not, the mandamus is awarded.

The writ in the first instance issues in an alternative form, requiring the party to do the act, or to show why he has not done it. The party may make a return to the writ by saying that he has not done the act for such and such reasons. Where the reasons returned are insufficient in law, the court quashes the return, and awards a peremptory mandamus requiring the party absolutely, and without allowing him any alternative, to do the act. Where the answer is apparently sufficient, the mandamus is at an end; and if the statements are untrue, the remedy is by action on the case for a false return, though in order to avoid expense and delay the party is allowed, in some cases, by the Statute 9 Anne, c. 20, and now in all cases, by 1 Will. IV. c. 21, to engraft an action upon the mandamus itself by traversing the return, that is, by putting in a plea contradicting the allegations contained in such return.

By the Common Law Procedure Act, 1854, it is enacted that in any action except replevin and ejectment, the plaintiff may endorse on his writ that he intends to claim a writ of mandamus, and thereupon he may in his declaration claim one, together with any other demand for which the action is brought. It has been held, however, that a party cannot be compelled under this Act to perform a contract entered into by him, but he can compel a company to register him as a shareholder. This Act does not do away with the prerogative writ of the Court of Queen's Bench before alluded to.

MANDARIN, a Portuguese term (from Port. *mandar*, Lat. *mandare*, 'to command') for a member of the Chinese official order of nobility. Mandarins are either civil or military: of the former there are nine classes, of the latter five. They are inferior in rank to the higher class of nobility, whose dignity more nearly resembles in character the British peerage, but form the ministry and magistracy of the country. The Chinese term corresponding to mandarin is *kwan*, which literally means, 'a public character.'

MANDATE, in Roman law, was a consensual contract in which one either by agreement or by tacit assent, undertook to perform some act gratuitously for another. When the service was remunerated the contract was one of *locatio conductio*; when no authority had been given to undertake the manage-

ment of the other's affairs, the act was only one of quasi-contract, and fell under the head of *negotiorum gestio*. A mandatory was responsible for even *levissima culpa*, and was only exonerated when the injury had arisen by *casus fortuitus*. Mandate was terminated either by revocation or by the death of either the mandant or mandatory.

In England mandate is a department of the law of Bailment. In Scotland mandate if accepted by the mandatory is still recognized as a binding contract, and, as in the Roman law, may be constituted either by writing or tacitly. But it has now been almost superseded by agency or factory, which is the employment of another for hire to manage any business as factor for the employer.

In judicial proceedings, when either the pursuer or defender is resident out of Scotland, his opponent is entitled to insist that a mandatory should be sisted in his place, who will be liable for the expenses of the suit if the result is unfavourable to his principal.

MANDELIC ACID (Germ. *Mandel*, 'an almond') is a white crystalline acid produced by the action of hydrochloric acid on oil of bitter almonds. Its formula is $C_{10}H_7O_5 + H_2O$, and it contains the elements of prussic acid and hydruet of benzoyle.

MANDEVILLE, SIR JOHN DE, was born at St. Albans about the year 1300. In 1327 he went to Palestine, where he joined the army of the infidels. He afterwards served in Egypt under the sultan, and in southern China under the khan of Cathay. He resided for three years at Peking, and appears to have travelled over a large part of Asia. After an absence of about thirty-three years, he returned to England, and wrote a narrative of his travels, which he dedicated to Edward III. From the extraordinary character of some of its incidents its author has obtained a proverbial reputation for mendacity. He wrote it first in Latin, then in French, and finally in English. He died November 17, 1371, at Liège, where he was buried. A MS. of his travels, contemporary with the author, is preserved in the Cottonian Library. The first edition printed in England is that of Wynkyn de Worde, at Westminster, 1499. An edition, with introduction and notes by J. O. Halliwell, was published in 1639.

MANDEVILLE, BERNARD DE, was born at Dort, in Holland, about 1670. He took the degree of Doctor of Medicine in Holland, and afterwards practised his profession in London. He does not appear to have had much success as a physician. His first work, 'The Virgin Unmasked, or Female Dialogues betwixt an elderly maiden Lady and her Niece,' was published in 1709. In 1714 he published a short poem, called 'The Grumbling Hive, or Knaves turned Honest,' to which he afterwards added long explanatory notes, recast it in prose, and then published the whole under the new title of 'The Fable of the Bees.' This work, which, however erroneous may be its views of morals and of society, bears all the marks of an honest and sincere inquiry into an important subject, exposed its author to much obloquy; as did also some other works which he wrote. He died January 21, 1733, aged sixty-three.

MANDIBLE (Lat. *Mandibula*, 'a jaw') is applied in Zoology to the lower jaw of mammals, to the upper or anterior pair of jaws of insects, and to both jaws of birds.

MANDIBULATA, the name given by several systematists to a group of insects, the structure of whose mouth is characterized by well-marked jaws or mandibles, and thus distinct from the *Haustellata*, or those with suckers. In the scheme of Stephens, the former includes the beetles, dragon flies, wasps, bees, &c., and the latter, the butterflies, moths, fleas, &c.; these words, however, are now seldom used in Entomology.

MANDINGOES. [SENEGAMBIA.]

MANDIOC, the American name of the Cassava plant, which furnishes the inhabitants of tropical America with a farinaceous food. There are two varieties: one called the sweet, the other the bitter. From the starch of the latter tapioca is prepared by elutriation and granulating on hot plates. This shrub, also known as *Jamipha manihot* (the *Manihot utilisima* of botanists) grows to a height of six feet. It belongs to the natural order of the Euphorbiaceæ, and in its raw state is poisonous.

MANDOLINE, a musical instrument of the lute kind, but smaller, having four strings, which are tuned in the same manner as those of the violin. The mandoline is still met with occasionally in Italy, but has fallen into disuse in most other parts of Europe.

MANDRAGORA, MANDRAKE. [ATROPA.]

MANDRILL. [BABOON.]

MANES, the name given by the Latins to souls separated from the body. The etymology of the word is uncertain; it is generally derived by ancient grammarians from an old word, *manus*, signifying 'good,' probably in the same sense as the Furies were called Eumenides by the Greeks. They were usually identified with the Lares, and so received the name Dii Manes. Public rites in their honour took place in the month of February.

The stones in the Roman burial-places, and their funeral urns, were generally inscribed with the letter D.M.S., that is, *Dis Manibus Sacrum* ('sacred to the Manes Gods'). There are many specimens of such funeral inscriptions in the Townley Gallery, British Museum.

MANETHO, an Egyptian writer, a native of Dióspolis, who is said to have lived in the time of Ptolemæus Philadelphus at Mende or Heliópolis, and to have been a man of great learning. He was a priest, and interpreter or recorder of religious usages, and of the religious and probably also historical writings. It is supposed that there was more than one person of the name of Manetho.

The only work of Manetho which has come down to us complete is a poem, in six books, in hexameter verse, on the influence of the stars (*ἁποτίλισματικὴ*), which was first published by Gronovius, Leyden, 1698, and has also been edited by Axtius and Rigler, Cologne, 1832. There are considerable fragments of a work of Manetho on the history of the ancient kings of Egypt, which was probably written by the Manetho who lived under Ptolemæus Philadelphus. It comprised the period from the earliest times to the death of the last Persian Darius. These are preserved in the treatise of Josephus against Apion. Manetho derived his history of the kings of Egypt, whom he divides into thirty classes, called dynasties, from the sacred records in the temple at Heliópolis.

MANFRED, natural son of the Emperor Frederic VOL. VIII.

II., was appointed by his father at his death, in 1250, regent of the kingdom of the Two Sicilies, until the arrival of his brother Conrad, the legitimate son and heir of Frederic. Upon the death of Conrad, and the reported death of Conradin, his son, Manfred was invited to assume the crown, which he retained by general consent, even after it was discovered that Conradin was still alive. But Manfred had to contend against the see of Rome, by which he was excommunicated. Urban IV. treated Manfred as a usurper, and bestowed the crown upon Charles, count of Anjou, brother of Louis IX. of France. Charles marched an army into the dominions of Manfred, who was killed under the walls of Benevento, 26th February, 1266. Manfred was a warm and enlightened patron of letters, was himself a poet, and is praised by the Neapolitan chroniclers for many great and noble qualities.

MANFREDONIA. [CAPITANATA.]

MANGALORE. [CANARA.]

MANGANESE, a metal first discovered by Scheele and Gahn, about 1774. Its natural compounds are very numerous, and the metal is easily separated from them. Manganese has a grayish colour, and resembles white cast iron in appearance; it is hard, brittle, and has a fasciculated crystalline structure; its specific gravity is 8.013; it is inodorous and tasteless, but when breathed upon emits a smell of hydrogen gas. By exposure to the air, manganese readily tarnishes by oxidizement, and even in a very short time attracts sufficient oxygen to lose its metallic lustre, and falls to a reddish brown powder; hence the necessity for preserving it immersed in naphtha. Even at common temperatures it slowly decomposes water; and at a red heat the decomposition is rapidly effected, and in both cases hydrogen gas is evolved, and oxide of manganese formed.

The ores of manganese are chiefly oxides. The principal among them are—*Hausmannite*, *Braunite*, *Manganite*, *Varvicite*, *Pyrolucite*, *Black Wad*, or *Hydrated Binoxide of Manganese*, *Pailomelane*, *Kobellite*, or *Manganese Blende*, *Arsenüret of Manganese*, *Cupreous Manganese*, *Kohlerite*, or *Carbonate of Manganese*, *Silicate of Manganese*, *Knebelite*, or *Silicate of Manganese and Iron*, *Ullmannite*, or *Phosphate of Manganese and Iron*. Many of these are crystalline; the rest massive.

Oxygen and Manganese combine in five proportions. The protoxide ($O^1 M^1$) is of a light green colour. It undergoes no change by exposure to the air. It is insoluble in water. When heated to 600° , it acquires oxygen, and is converted into red oxide; and sometimes, by exposure to a strong heat, it undergoes combustion as well as oxidation. It combines readily with acids, and dissolves in them, even when dilute and cold, without effervescence; and the solutions are colourless. It is this oxide which is the base of all the common salts of manganese. The red oxide ($O^4 M^3$) suffers no change by exposure to the air, is insoluble in water, and has a reddish colour. The nitric, sulphuric, and hydrochloric acids all decompose it, the two first separating it into protoxide and binoxide; and they dissolve the first and leave the second insoluble. The sesquioxide ($O^3 M^2$) is brown, except when obtained from the nitrate, and then it is nearly black. It is insoluble in water, suffers no change by exposure to the air,

is decomposed by dilute nitric and sulphuric acids, being separated by them into protoxide, which they dissolve, and peroxide, which remains insoluble. The *peroxide* ($O^2 M^1$) is black, or brownish black, unalterable in the air, insoluble in water, decomposed by heat into red oxide and oxygen gas, insoluble in alkalies, unacted upon by nitric acid or dilute sulphuric. Its equivalent is 44. There is a fifth oxide ($O^7 M^4$) forming the mineral *varvicite*.

There are two acids of manganese which are entirely artificial compounds, namely, the manganic acid and per-, or, more properly, the hyper-manganic acid. *Manganic acid* ($O^3 M^1$) has not hitherto been obtained in a separate state; but manganate of potash is easily prepared. It is of a green colour, and has long been known by the name of *mineral chameleon*, on account of the change of colour which the solution undergoes during the process. *Permanganic acid* ($O^7 M^2$) has a fine red colour, and is rapidly decomposed by organic matter, as paper or linen. It bleaches coloured matter; the aqueous solution begins to decompose when heated to 86° , and is totally decomposed at 212° ; oxygen is given out, and binoxide of manganese is precipitated. Its salts are more permanent than the acid, and when heated they yield oxygen gas, deflagrate when thrown on burning charcoal, and detonate violently with phosphorus.

Chlorine and Manganese form two compounds. The *protochloride* ($Chl.^1 M^1$) is a pink-coloured lamellated mass, which attracts moisture readily from the air, and is very soluble in water, forming a solution which is nearly or quite colourless. The *perchloride* ($Chl.^7 M^2$) is a greenish-coloured vapour, which, by cooling to 4° , condenses into a greenish brown-coloured fluid. *Sulphur and Manganese* may be combined by heating a mixture of sulphur and the binoxide, from which results a *sulphuret* ($S^1 M^1$).

According to Berzelius, manganese combines with several other metals, as gold, silver, copper, tin, and iron; with the last-mentioned, combination takes place readily, and the iron is rendered harder, whiter, and more brittle by it; and it is stated that iron which contains manganese is best adapted for making steel. A small quantity of iron causes manganese to obey the magnet, and renders it less oxidable.

The salts of manganese are compounds of very little importance.

Oxide of manganese tinges glass an amethystine colour.

The oxides of manganese, and especially the binoxide, as containing most oxygen, are largely employed in the preparation of chlorine, for the manufacture of bleaching powder, or chloride of lime. The latter is employed in glass-making to correct the yellow colour which oxide of iron is apt to impart to the glass, and in making the black enamel of pottery. Sulphate of manganese is also used to give a brown colour in calico-printing.

Action of Manganese on the Body.—The extensive employment of black oxide of manganese in the preparation of bleaching powder produces in some of the workmen a form of paralysis which should be early noticed, inasmuch as, after it is thoroughly established, it seems altogether incurable, and the only chance of escape is the complete abandoning of the occupation. It is limited to paralysis of the

lower extremities, affecting the motor nerves only, for the sensibility is unimpaired.

Binoxide of manganese has been used internally in pills, and also as a gargle; externally as an ointment in some obstinate cutaneous affections. It does not appear entitled to much attention. Hydrochlorate, and still more sulphate of manganese, deserve attention as chologogue cathartics, or promoters of the secretion of bile. The latter salt has a cooling and bitter taste, resembling that of Glauber salt. It is useful in gout.

MANGANITE, a mineral of a grayish-black colour, which occurs crystallized or massive, with a metallic lustre. It is the hydrated sesquioxide of manganese; and its constituents are manganese, 62.93; oxygen, 20.97; and water, 10.10. Specific gravity, 4.328.

MANGE (Fr. *démanger*, 'to itch'), an eruptive disease to which many domestic animals, and particularly dogs, are subject. It usually occurs as the result of dirt and confinement, bad or deficient food, or some other circumstances producing a generally unhealthy condition.

MANGIFERA, a genus of trees of the natural family of *Terebinthaceæ*, tribe *Anacardiæ*. Three or four species of this genus are enumerated: as *M. fetida* of Loureiro, a native of Cochinchina and the Moluccas; *M. laziflora*, indigenous in Mauritius; and *M. sylvatica*, of Roxburgh, a native of the hilly districts bordering on Silhet, where it grows to a great size. However, the Mango Tree, *Mangifera Indica*, is alone of any consequence, and this as forming one of the most grateful fruits of the tropical parts of Asia. The trees grow to a great size, with an erect trunk and dark-coloured cracked bark. The wood is of a whitish or a dull gray colour, porous, yet pretty durable if kept dry.

MANGLE. [CALENDERING.]

MANGO. [MANGIFERA.]

MANGOLD WURZEL, or **MANGEL WURZEL**, the root of the *Beta vulgaris macroshiza*, is cultivated for the food of cattle, and for its saccharine juice. [BEET.]

MANGOSTEEN, the fruit of the *Garcinia mangostana*, which flourishes in Java and the Molucca Islands, is of the size of an orange, and of a luscious flavour. [GARCINIA.]

MANGROVE. [RHIZOPHORA.]

MANHEIM, or **MANNHEIM**, the capital of the circle of Unter-Rhein, in the grand duchy of Baden, is situated in $49^\circ 29'$ N. lat., $8^\circ 28'$ E. long., in a very fertile plain, at the junction of the Neckar with the Rhine, and had, in 1861, 27,172 inhabitants. Over both rivers there are bridges of boats. Mannheim is built with great regularity; it consists of several squares and of broad straight streets that cross each other at right angles. The town has quite a modern air, having been almost entirely reconstructed since the close of the last century, when the French were obliged to surrender it to the Austrians after a bombardment which laid the greater part of it in ruins. The principal street leads from the Neckar Gate to the palace of the grand duke, built in 1720, which is a very magnificent edifice, and one of the finest of the kind in Germany. The right wing contains a gallery of pictures, a cabinet of natural history, a collection of plaster casts of the

most celebrated antiques, and a library of 60,000 volumes. Manheim has also several Lutheran and Roman Catholic churches, an observatory, and a botanic garden. The fortifications having been entirely demolished by the French, and the site subsequently converted into gardens, the inhabitants enjoy the benefit of beautiful promenades, besides the fine park of the palace, which is nearly 200 acres in extent. There are manufactories of tobacco, shawls, linen, and playing cards, besides bleaching-grounds and tanneries. There is an active trade by the rivers and railways; the latter connecting it with the chief towns of Germany.

MANICHÆANS, an heretical Christian sect, who derived their name from Mani, as he is called by the Persians and Arabians, or Manes or Manichæus, according to the Greek and Roman writers. This sect arose about the end of the third, or the beginning of the fourth century of the Christian era. The Manichæans believed, like the Magi, in two eternal principles, from which all things proceed; namely, light and darkness, which are respectively subject to the dominion of two beings, one the god of good, and the other the god of evil; and also that those souls which obeyed the laws delivered by Christ, as explained by himself the Comforter, and which struggled against the lusts of a corrupt nature, would, on their death, be delivered from their sinful bodies, and ascend to the regions of light; but that those souls which neglected to struggle against their corrupt natures would pass after death into the bodies of animals or other beings, until they had expiated their guilt. The doctrines of the sect were contained in four works, said to have been written by Mani himself, which were entitled respectively 'Mysteries,' 'Chapters,' 'Gospel,' and 'Treasury;' but we know little or nothing of their contents.

The Manichæans never appear to have been very numerous, but were spread over almost all parts of the Christian world. Much valuable information concerning this sect may be found in the writings of Augustine, who was for nine years a zealous supporter of their doctrines.

The Paulicians are generally considered to be a branch of the sect, and are supposed to have first appeared in the seventh century in Armenia. They continued to exist till a very late period in ecclesiastical history. In the eleventh and twelfth centuries the doctrines of the Paulicians were introduced into Italy and France, with considerable success.

MANIFESTO. The name given to documents issued by kings or governments on very special occasions, such as the declaration of war; in which case it generally sets forth the reasons which have induced a government to decide on such a course.

MANIFOLD WRITER. [COPYING MACHINE.]

MANILIUS, MARCUS or CAIUS, a Latin poet, who wrote a work on astronomy, called 'Astronomicon,' in five books. It is the opinion of Bentley that he was born in Asia, and lived in the time of Augustus Cæsar.

The 'Astronomicon' does not appear to be complete. The five books which are extant treat principally of the fixed stars; but the poet promises in many parts of his work to give an account of the planets. The 'Astronomicon' contains several passages which are not unworthy to be compared

with some of the best writings of the Augustan age; but the subject gave the author little opportunity for the exercise of his poetical powers. The best editions are by Bentley, London, 1739, and Stoeber, 1767. It has been translated into English verse by Creech, London, 1700.

MANILLA. [PHILIPPINES.]

MANIOC or MANDIOC. [CASSAVA.]

MANIPULATION, in Chemistry, embraces every part of the subject which is of a mechanical nature, such as the operations of weighing, measuring, the application of heat and electricity, the various modes of effecting solution, precipitation, distillation, and sublimation, and, in fact, every step in chemical research includes manipulation. The whole subject is treated in Faraday's 'Chemical Manipulation.'

MAN'LII, the name of one of the most illustrious patrician *gentes* of ancient Rome. Those most worthy of notice are:—

1. *Marcus Manlius Capitolinus*, who was consul B.C. 392 (Liv. v. 31), and was the means of preserving the capitol when it was nearly captured by the Gauls (Liv. v. 47), from which he obtained his surname. He afterwards became a warm supporter of the popular party against his own order, in consequence of which he was accused of aiming at the kingly power. The circumstances attending his trial and death are involved in much obscurity. It would appear that he was accused before the centuries and was acquitted; and that afterwards, seeing that the patrician party were determined on his destruction, he seized upon the capitol, and prepared to defend it by arms. In consequence Camillus, his personal enemy, was appointed dictator, and the *curiæ* (i.e., the patrician assembly) condemned him to death. (Niebuhr, 'Roman History,' vol. ii., p. 610, 611, Engl. transl.; Liv. vi. 11, 14, 20.) Manlius was thrown from the Tarpeian rock, B.C. 384.

2. *Titus Manlius Capitolinus Torquatus*, son of L. Manlius, surnamed Imperiosus, who was dictator B.C. 361. In the following year Manlius distinguished himself by slaying in single combat a Gaul of gigantic size on the banks of the Anio. In consequence of his taking a chain (*torques*) from the dead body of his enemy, he received the surname of Torquatus, by which he is best known.

Manlius filled the office of dictator twice, and he was consul at least three times. In his third consulship he defeated the Latins. In the same campaign he put his own son to death for having engaged in single combat with one of the enemy, contrary to his orders.

3. *Titus Manlius Torquatus* was consul B.C. 235, and obtained a triumph on account of his victories in Sardinia. In his second consulship, B.C. 224, he conquered the Gauls. The temple of Janus was closed during his first consulship, one of the few occasions in Roman history.

4. *Cneius Manlius Vulso* was consul B.C. 189, and appointed to the command of the war against the Gauls in Galatia, whom he entirely subdued. An account of this war is given by Livy (xxxviii. 12–17), and Polybius (xxii. 16–22).

MANNA, the concrete juice of the *Ornus Europæa* and *Ornus rotundifolia*, two species of ash which are natives of the south of Europe, growing abundantly in Sicily, Calabria, Apulia, &c. The juice

exudes spontaneously in warm dry weather, and concretes upon the bark of the tree; the finest manna is, however, procured by making longitudinal incisions of about three inches long. The manna flows at first in the form of a thick juice, which gradually concretes. The finest kind is called Calabrian or flake manna; it is in pieces of a pale yellowish white colour, is light, rather dry, and brittle, and it bears frequently the impression of the branch on which it concretes. It has a slight peculiar odour, and a sweetish taste, mixed with a slight degree of bitterness, and altogether leaves a disagreeable impression. Although it has a composition not unlike sugar, it is not fermentable.

Manna is employed as a gentle laxative, for children or persons of weak habits. It is, however, seldom exhibited alone, but as an adjunct to more active medicines, as senna, rhubarb, &c.

Besides the genuine manna above described, sweetish secretions are exuded by some other plants, chiefly tropical, which are usually considered to be kinds of manna. Manna belongs to the same series of vegetable bodies as sugar, and like that compound is widely distributed in the vegetable kingdom. The quantity of manna imported into the United Kingdom in 1864 was 25,144 lbs.; value, 29377.

MANNA CROUP, or MANNA GROATS, a preparation made in Russia from the hard wheats of Odessa and Taganrog. It is much used for puddings, and is precisely similar to the Italian macolina. [MACARONI.]

MANNYNG, ROBERT, is more usually called Robert de Brunne. He owes this name to his having been a Gilbertine canon in the monastery of Brunne or Bourne in Lincolnshire. He lived in the reigns of Edward I. and his successor, and was the writer of one of the earliest of the Metrical Chronicles whose language can be called English. His work, however, is merely a translation from the French. It is in two parts: the first translated from the 'Brut d'Angleterre' and 'Roman de Rou' of Wace and Gaimar, begins with Æneas and ends with Cadwallader; the second, from Cadwallader to Edward I., is translated from the Chronicle of Peter Langtoft. The entire work was completed about 1388.

MANOMETER (from two Greek words signifying 'thin' or 'rare,' and 'a measure') is the name given to instruments which measure the rarity of the atmosphere, or other gases. The most convenient manometer, and consequently that in most general use, consists of a siphon barometer, the basin of which is inclosed air-tight in a globular or other conveniently shaped vessel, furnished with a number of cocks, by means of which, and the pneumatic pump, the contained gas may be removed, and other gases successively substituted in its place. If equal parts by weight of different gases be thus successively introduced, they will not be affected by any change which may take place in the surrounding atmosphere except in so far as such change may affect their temperature; so that, providing the temperature remain constant, the relative tensions of these gases will be accurately measured by the weight of the mercurial column suspended in the longer arm of the barometer above the level of the mercury in the basin, care being taken to allow for any variation in the capacity of the receiver, arising from alteration in the level of

the mercury in the basin, and likewise for the small tension always indicated by the barometer immediately previous to the introduction of a fresh gas, arising from the impossibility of forming a perfect vacuum.

MANOR (*Manerium*). At the time of the Norman Conquest *manerius* or *manerium* (from *manere*, 'to dwell') denoted a large mansion or dwelling. The modern English manor derives its origin from subinfeudation, as it existed before the modifications of the system of tenures introduced in 1225 by Magna Charta, and the still more important alterations made in 1290 by the statute 'Quia Emptores,' and in 1324 by the statute 'De Prærogativâ Regis,' by which statutes the granting land in fee simple, to be held by the grantee as a tenant or vassal to the grantor, was stopped.

Where a subinfeudation made by A to B extended to the whole of A's land, nothing remained in A but a seigniorship with the ordinary feudal incidents of tenure, and such rents or other services as were reserved. This interest in A was a seigniorship in gross; that is, a seigniorship held by itself, unattached to any land, an incorporeal seigniorship, termed by the French feudists '*un fief en l'air*.' But in the case of subinfeudation of part of the land, the ordinary mode of proceeding was this:—A, a large proprietor, having a mansion and land at Dale, created a subtenure in a portion of his land by granting such portion to B and his heirs, to hold of A and his heirs, as of A's *manerium* (mansion) of Dale, which words created an implied condition that B should perform the service of attending, with the other tenants of A holding by virtue of similar subinfeudations, at A's halmote of Dale, that is, at A's court-meeting in the hall of A's mansion at Dale (afterwards called A's court-baron of his manor of Dale), for the purpose of deciding judicially all disputes among A's free tenants holding of him by the same tenure as B, in respect of their lands so holden, and also all actions brought by persons claiming such lands.

Upon this subinfeudation being effected, A would continue to be the owner of the mansion of Dale, and of that part of the land of Dale of which he had made no subinfeudation in *demesne* (in *dominio suo*), as his own immediate property; and he would have the seigniorship of lands of which B and others had been subinfeoffed, as a seigniorship appendant or legally annexed to the mansion of Dale, and to the *demesnes* of Dale, of which the mansion formed part.

This conjoint or complex estate, taking its denomination from the mansion (*manerium*), which was considered as its head, by degrees acquired the name of *Manerium* or *Manor*.

A Manor then *originally* consisted of lands in *demesne*, upon which the lord had a mansion, and to which lands and mansion, and more especially to the mansion, there was appendant a seigniorship over freeholders qualified in respect of quantity of estate (i.e., by a tenancy for life at the least, if not a tenancy in fee-simple), and sufficient in point of number to constitute a court-baron. These freeholders were called *vasavors*, and their lands '*tenemental lands*,' i.e., lands granted out in tenure, to distinguish them from the lord's *demesnes*. These *tenemental* lands, anciently known by the denomination of *vasavories*, though held of the manor and within

the seigniori (or, as it was usually termed, within the fee) of the lord, were not considered as part of the manor; but the services issuing from such tenemental lands were part of the manor and essential to its existence.

Afterwards it was sufficient if the site of a mansion, at which the services had been reserved, formed part of the demesnes; and at last, this vestige of the origin of the name of the estate was dispensed with, and if the lord retained any portion of the land, so that there would be some demesnes to which the seigniori over the freehold tenants of the manor, and the services rendered by them, might continue to be appendant, the compound estate called a manor was not dissolved, whether it could be shown that a mansion had ever stood on the part of the demesnes or lands retained or not, and even if the lord had aliened and severed from his demesnes the spot on which the mansion had once stood.

A Manor is commonly said to consist of demesnes and services, which have been called the 'material causes;' but other things may also be members and parcel of a manor.

Manors in Ancient Demesne are those manors which, though now mostly in the hands of subjects, formed part of the royal domain at the time of the Conquest, and are designated in Domesday as 'terra regis.'

MANOR-HAMILTON. [LEITRIM.]

MANOSQUE. [ALPES, BASSES.]

MANRESA. [CATALUÑA.]

MANS, LE, the capital formerly of the province of Maine, now of the department of Sarthe in France, stands on the right bank of the Sarthe, here crossed by three bridges, in 48° 0' N. lat., 0° 11' E. long., at a distance of 132 miles S.W. from Paris, and has 37,209 inhabitants. The cathedral of St.-Julien, famous for its choir and painted windows, and dating from the thirteenth century, contains the tomb of Berengaria, Cœur-de-Lion's queen. The church De-la-Couture, which dates from the twelfth century, and that of Notre-Dame-du-Pré, from the eleventh century, are very remarkable buildings. Le-Mans is partly inclosed by Roman walls. It has a town-hall, prefecture, theatre, two hospitals, museum, communal college, and a public library of 45,000 volumes. It gives title to a bishop. The manufactures consist of coarse woollens, lace, honey, wax candles, linen, soap, hosiery, blankets, woollen yarn, paper, and leather. There are also marble works and bleach mills. The town is noted for its poultry, of which it sends a large supply to the metropolis.

Le-Mans was the birth-place of Henry II., the first of the Plantagenet kings of England. The last struggle between the French republicans and the Vendean forces took place here in 1793. (*Dictionnaire de la France*.)

MANSARD, FRANÇOIS, was born at Paris in 1598. At the age of twenty-two he distinguished himself as an architect by his restoration of the Hôtel Toulouse; and a short time afterwards he was commissioned to execute the portal of the church of the Feuillans, in the Rue St. Honoré. From this time he was much employed. The Château des Maisons is considered his *chef-d'œuvre* among his mansions, and of his churches the most noted is that of the Val de Grace at Paris, but none of his works

are in a pure style of architecture. He died in 1666. He is said to have been the inventor of the curb roof, called after him a *Mansard*, which consists of two planes on each side, a steeper one below and a flatter one above, and admits of an attic being lodged in it.

MANSARD, JULES HARDOUIN, a nephew of the preceding, was born in 1645. He was brought up by François to his own profession, in which he afterwards became very celebrated. He was the architect of Versailles, which Sir C. Wren has described as 'mere heaps of littleness.' After Versailles, the work which has chiefly contributed to his reputation is the dome of the church of the Invalides at Paris. He died in 1708. His somewhat partial biographer, Quatremère de Quincy, admits that he had 'une certaine médiocrité de goût.'

MANSE, in Scottish law, originally meant a determinate quantity of ground, the extent of which is not known, fit either for pasture or tillage, set apart for the use of the clergyman of every rural parish. The term is now applied to the dwelling house, including stable, byre, barn, and other offices to which he is entitled by law; the portion of land with which he is also provided being called his glebe. Ministers of parishes within the bounds of royal burghs are not entitled to manses; but where the parish is partly rural and partly burgh royal, the heritors are bound to provide him with a manse. The burden of erecting and supporting the manse lies upon the heritors who are the proprietors of lands within the parish. By the Act 1663, c. 21, the expense of building the manse is limited to a maximum of 1000*l.* Scots (83*l.* 6*s.* 8*d.* sterling), but this statute is no longer in observance. On the completion of the building the heritors may apply to the presbytery of the parish, who upon visitation will pronounce the manse a free manse, the effect of which is to oblige the minister to keep the manse in tenantable condition during his incumbency. When a manse stands in need of additions and repairs, or when a new manse is required, the minister may petition the presbytery to have the same examined; and after consideration of plan and estimates, the presbytery will grant decree against the heritors for the sum necessary for the required alterations.

Over and above their proper stipend clergymen of rural parishes are entitled to four acres of arable land in name of glebe, and to grass for a horse and two cows as grass glebe.

MANSFIELD. [NOTTINGHAMSHIRE.]

MANSFIELD, WILLIAM MURRAY, EARL OF, was born in the ancient palace of Scone, on the 2nd of March, 1705. He was the fourth son of Andrew Viscount Stormont. At the age of three he was removed to London, and in 1719 he was admitted a king's scholar at Westminster school. On the 18th of June, 1723, he was entered at Christ Church, Oxford, where, as before at Westminster, he distinguished himself by his classical attainments, Having taken his degree of M.A. he left the university in 1730, and after travelling some time abroad he was called to the bar in Michaelmas Term, 1731. It appears that he got into some practice soon after being called to the bar. In 1743 he was appointed solicitor-general, and obtained a seat in the House of Commons, where his eloquence and legal knowledge soon acquired considerable influence. Murray

and Pitt (Lord Chatham) were opposed to each other as the best speakers of their respective parties.

In 1754 Mr. Murray was made attorney-general, and in 1756 received the appointment of chief-justice of the King's Bench, and was immediately created a peer, by the title of Baron Mansfield, of Mansfield in the county of Nottingham. On his elevation to the seat of chief-justice, Lord Mansfield, contrary to the general usage, became a member of the Cabinet.

In the riots of 1780 Lord Mansfield's house in Bloomsbury Square was attacked and set fire to by the populace. His library of books and MSS., his private papers, pictures, furniture, and other valuables were all consumed. Though the Treasury, in pursuance of a vote of the House of Commons, applied for the particulars and the amount of his loss, with a view to compensation, his lordship declined returning any account of it, lest, he said in his letter to the Treasury, 'it might seem a claim or expectation of being indemnified.'

After having presided for upwards of thirty years in the Court of King's Bench, he retired in 1788. He died on the 20th of March, 1793, in the eighty-ninth year of his age. The last words he was heard to utter were: 'Let me sleep, let me sleep.' He left no issue. The earldom of Mansfield, which was granted to him in 1776, descended to his nephew, Viscount Stormont. A monument by Flaxman was erected to his memory in Westminster Abbey.

Lord Mansfield's acute and powerful intellect enabled him to take a clear and comprehensive view of every case. The depth of his legal learning has been questioned; probably not without reason. He showed the greatest ability in improving by his judicial decisions various branches of commercial law. In matters of religion he was tolerable both in Parliament and on the bench. He was undoubtedly a man of great abilities and enlarged views, and for this very reason less adapted than some judges to expound those technicalities which mark the deviation of English law from the standard of general jurisprudence.

MANSLAUGHTER. [MURDER.]

MANTEGNA, ANDREA, was born at Padua in 1431. His parents were in humble life. He was a pupil of Francesco Squarcione. His chief residence and his school were at Mantua, where he settled under the patronage of the Marquis Lodovico Gonzaga, but worked occasionally at other places, especially Rome. 'The Triumph of Julius Cæsar' was purchased by King Charles I. from the Gonzaga family among other pictures. This, his greatest and most esteemed work, consisting of nine tempera pictures, each 9 feet high and 9 feet wide, is now at Hampton Court. Unhappily it was coarsely painted over by Laguerre, in the time of William III. Mantegna died at Mantua on the 13th of September, 1506.

MANTES. [SEINE-ET-OISE.]

MANTIDÆ, a family of orthopterous insects, the principal genera of which are, *Heteronytarsus*, *Eremiophila*, and *Mantis*.

The Mantidæ are found in all warm countries, are exceedingly numerous, and remarkable for the grotesque forms which they usually assume. Their resemblance to a portion of a plant is often so great, that it is only by their motions they can be discovered. The names *religiosa*, *precaria*, *sancta*, &c., have been

applied to certain species on account of a peculiarity in their habits—that of erecting the thorax at an angle with the body, and placing together the large fore-legs, like the hands of a person when at prayer; in this position they will sometimes remain perfectly motionless for several hours. Their food consists of flies and other insects, which they are exceedingly dexterous in catching by means of their fore-legs; the prey is held by the fore-leg by bending back the tibia against the femur; the opposing surfaces of these two portions of the legs being covered with spines, enables them to retain their prey in this manner, and to convey it to the mouth.

The eggs, deposited by the female *Mantis* upon plants, are covered by a glutinous substance, which soon hardens into a kind of case, where they are arranged in a symmetrical manner. The form of the case varies according to the species. The young, when hatched, resemble the parents, except in size and in being destitute of wings.

MANTINEIA was situated in the east part of Arcadia, in an elevated plain of considerable extent, which was bounded on the north by the plain of Orchómenus, and on the south by that of Tégea. The Mantineans had a democratical form of government, and were closely connected with Argos.

In B.C. 385 the Spartans took Mantinea and destroyed the city. After the battle of Leuctra, the Mantineans rebuilt their city; and it was in the vicinity of their town that the battle was fought, B.C. 362, between the Spartans and Thebans, in which Epaminondas fell. Mantinea, in later times, joined the Achæan league. Pausanias, who visited this city in the second century, describes it as a large and flourishing place, and has devoted a considerable part of his eighth book to a description of its works of art.

The ruins of Mantinea, now called *Paleopoli*, are still considerable. The walls are nearly entire.

MANTLET, a temporary fortification to protect gunners from the bullets of the enemy. It is made so that it may be hoisted while aim is being taken, and then lowered so as to cover the whole opening in the embrasure, casemate, or port-hole, except a small aperture for the muzzle of the gun. They are generally made of solid planks of wood or iron plates; but during the late Crimean war the Russians constructed some very skilful ones of plaited rope. Mantlets have become more used than ever of late years, in consequence of the precision and length of range of the modern rifles.

MANTUA (or MANTOVA), a city of great historic importance in northern Italy, twenty-two miles S.S.W. of Verona, stands on an island about five miles in circumference, in the middle of a lagoon formed by the Mincio, and is joined to the mainland by causeways, the shortest of which is about 1000 feet in length. The town is regularly and very strongly fortified. It is well built, with wide streets and squares, and contains many handsome structures. The principal buildings are—the cathedral, one of the finest in Italy; the church of Sant-Andrea; the churches of San-Maurizio and San-Sebastiano; the house of Giulio Romano, whose works as a painter and an architect form the greatest glory of the city; the church of Santa-Barbara, rich in paintings; the public library of 80,000 volumes, and the museum,

in which is a valuable sculpture gallery; the ducal palace, an old vast irregular structure, partly rebuilt and decorated by Giulio Romano, which contains some good paintings; the *Palazzo Vecchio*, in which Napoleon I. held his court; several convents, a Jew's synagogue, civil hospital, two orphan and one Jew's asylums; arsenal, cavalry barracks, theatre, sculpture gallery, and the gates and bridges of Mantua, especially the gate dei Mulini, by Giulio Romano. A palace outside of the town, called Palazzo del Tè, was originally intended for stables for the dukes Gonzaga, but under the direction of Giulio Romano it grew into a vast palace. There is a good fresco there. The town of Mantua contained in 1862, 29,884 inhabitants, 2500 of whom are Jews, whose commercial intercourse and social privileges are more extensive in this city than in any other in Italy.

Mantua has a lyceum, gymnasium, academy of fine arts, several scientific and literary institutions, botanic garden, and numerous collections in science and art. From its situation, the place is extremely unhealthy. The manufactures comprise silk, linen, and woollen fabrics, paper, cordage, leather, and parchment. Virgil was born at Andes, (now Pietole,) 3 miles S.E. of this city.

After the conquest of Italy by Charlemagne in the eighth century, Mantua became the capital of a republic. It then came into the possession of the dukes of Gonzaga, to whom it belonged till it fell to Austria in 1708. It was taken by Napoleon I. in 1797, and was the capital of the French department of the Mincio till 1814. The greater part of the province of Mantua was given over to Italy in 1859; and the city itself will, as one result of the recent war, now form a part of the Italian kingdom (August, 1866).

MANTUA'NO, the common name of a family of artists of Mantua, of the sixteenth century. The proper name appears to have been *Ghisi*, but few particulars regarding the lives of its members are known. *Giovanni Battista*, called *Giovanni Mantuano*, and also Bertano, was painter, sculptor, engraver, and architect. He wrote a commentary on Vitruvius, which is dated 1558. *Giorgio Ghisi*, called *Giorgio Mantuano*, was born at Mantua about 1520. He was a painter and an engraver, and was still living in 1578. Bartsch describes 129 prints by *Adamo Ghisi*, called also *Mantuano*; and 46 by *Diana Ghisi*, called *Mantuana*. Those of the former are dated from 1566 to 1576, and those of Diana from 1575 to 1588.

MANUAL ALPHABET. [DACTYLOLOGY.]

MANUEL, NICOLAUS, was born at Berne in 1484. He is the Emanuel Tedesco who studied under Titian at Venice about 1511, and he became celebrated for a series of forty-six pictures (probably in distemper) of the Dance of Death, *Totentanz*, painted in fresco between 1514 and 1522, in the cloister of the Dominican convent at Berne, destroyed long since, but of which the compositions have been preserved in prints and copies. He also produced various popular poems and songs in the Swiss dialect, full of humour and satire. His 'Fastnachtspiele,' or Dramatic Moralities and Mysteries, which he began to compose about 1522, are marked by the same qualities. He died in 1530. An elaborate memoir of him was published in 1837 by Dr. Grüneisen.

MANUEL, FRANCISCO, was born at Lisbon

in 1734. His first study was music, but he afterwards devoted himself entirely to literature, and more especially to poetry. His odes to D'Albuquerque and Washington are deservedly admired. His liberal opinions brought upon him the hostility of the Inquisition, but he saved himself by flying to Paris in 1788; in which city he resided till February 25, 1819, when he died.

MANUMISSION. [LIBERTINUS.]

MANURA, or MENU'RA, Dr. Shaw's and Dr. Latham's name for a single genus of birds, whose place in the system has occasioned some differences of opinion among ornithologists.

Two species only are known, viz., *Manura superba*, *M. lyra*, or *lyrata*, Shaw, Latham; *M. paradisea*, Vieill.; *M. Novæ Hollandiæ*; and *Manura Alberti*, discovered in 1850, and named by Mr. Gould in honour of the late prince consort. The *Manura*, or Lyre-bird of Australia, is, it must be confessed, a remarkable species; and we cannot wonder that some have placed it in the Insectorial order, near the Thrushes and Orioles (Temminck, Cuvier), while others have regarded it as a rasorial or gallinaceous bird (Vieillot, Vigors, Swainson, and others).

Lyre-bird (*Manura superba*).

The *Manura* is decidedly not rasorial. It is a song-bird, in some respects, notwithstanding its size, allied to the wrens; in other respects to the thrushes, or Brèves (*Pitta*). Mr. Gould makes the *Menurinae* a sub-family of the *Sylviadæ*, and we believe him to be correct in his opinion.

Speaking of the genus *Manura*, Mr. Gould says, 'It might have been expected that the various explorations which have of late years been made into the previously unknown regions of Australia would have led to the discovery of some additional species of this genus, or of some new form more nearly allied to it, than those with which it is associated; but nothing of the kind has occurred. This remarkable bird is not only confined to Australia,

but exclusively to the south-eastern part of the country. I regret to say that I have not been able to gain any further information respecting its nitrification, although I have urged many persons in Australia to pay particular attention to the subject.

MANURES. Under this name we include every substance used to amend the soil, or to restore to it some particular principle or ingredient which has been exhausted in the course of cultivation. According to their respective modes of action manures may be divided into mechanical, chemical, and physiological, though many rank at once under all these heads. A mechanical manure, or 'amender,' serves merely to improve the texture of the soil, so as to render it more compact, or if needful, more permeable to moisture, air, and the root-fibres of the plants. Thus sand or coal ashes added to a stiff clay, and clay or marl mixed with a soil of loose sand or of peat, are instances of mechanical manures. Their value when judiciously applied is extremely great, since no matter what may be the chemical constitution of the soil, it cannot be fruitful if so light as to allow moisture to escape too rapidly, and permit the roots of the plants to be loosened by the wind; or if, on the other hand, it allows water to stagnate in its texture. When a soil is in fine mechanical condition it will not bake together after being wet, and when dried will rapidly gain weight by condensing watery vapour and gases in its pores.

Chemical manures supply to the soil some necessary ingredient or ingredients, either naturally wanting or which may have been removed by the crops cultivated. Upon the use of this class of manures great light has been thrown by two principles established by Liebig, Boussingault, and other modern inquirers:—firstly, that the food of plants, like that of animals, is *specific*, one kind preferring what another rejects; and secondly, that all the substances removed annually from a field by the crops should be restored to it by the manures applied. In illustration of the specific character of the food of plants we may mention the fondness of the onion, lily, tulip, &c., for compounds of soda; lime, which is indispensable to the rose, the carnation, clover, &c., is poison to rhododendrons, azaleas, heaths, &c.

In compensating a field for the losses caused by any particular crops, the attention of the agriculturist is mainly turned to those substances in which soils are ordinarily poorest, *i.e.*, to phosphoric acid, to combined nitrogen (salts of ammonia, or of nitric acid, or organic nitrogenous matter capable of conversion into the former), and in a less degree to soluble silica, and the salts of potash. Not that these substances are more essential to vegetable life than carbonic acid, water, salts of soda, lime, magnesia, iron, &c., but being less plentiful they are most readily exhausted.

Physiological manures—a class as yet little understood—neither amend the texture of the soil nor supply any ingredient which would otherwise be wanting, but yet exercise a distinct beneficial influence upon vegetation. Thus turnips experimentally treated with oil have grown to an enormous size. Yet oils contain merely carbon, hydrogen, and oxygen—substances of which plants have an unlimited supply. We can only, therefore, conclude that manures of this class enable vegetables to assimilate nutriment

to a greater extent than is possible without their help.

Amongst manures the first place belongs to **GUANO**. The mixtures known as superphosphates, and prepared chiefly from **BOXES**, coprolites, &c., are also of great importance. Their value depends mainly upon the soluble biphosphate of lime, along with neutral phosphate in a fine state of division. Excellent manures are also prepared from blood, refuse fish, glue-maker's waste, hair, horn-shavings, and leather scraps, rendered soluble by means of sulphuric or hydrochloric acid. The crude sulphate of ammonia and the nitrate of soda are valuable sources of nitrogen, as are also, in a lower degree, oil-cake and soot.

The dung and urine of domestic animals, though of far less value than most of the above, must always play an important part in agriculture. Unfortunately they are often collected and stored in such a negligent manner that their best constituents are wasted. Their soluble parts are allowed to be washed away, whilst the ammonia escapes in vapours. Dung heaps should always be screened as much as possible from the sun and wind, as also from rain, and should be placed where their drainage may be secured for use. If sprinkled from time to time with sulphuric acid diluted with 100 times its weight of water, much waste will be prevented. So large a proportion of farm-yard manure consists of water and other comparatively useless matter, that 100 tons are only equal in efficiency to from seven to eight tons of good guano. Night-soil is a more powerful manure, when not mixed with cinders and similar rubbish. As a top-dressing for pastures it is objectionable, as it gives to the grass a flavour offensive to cattle. As prepared and dried in France under the name of *poudrette*, it has about ten times the value of ordinary farm-yard manure. The sewage of towns contains a vast quantity of fertilizing matter, such as urine, soap-suds, and many other kinds of refuse, domestic and manufacturing. The whole, however, is so largely diluted with water that its agricultural application is a yet unsolved problem, except where lands lie below the town in a situation adapted for irrigation. Charcoal, whether of bones, wood, or peat, is a valuable addition to manures, on account of its property of absorbing and retaining in its pores gases and vapours. Unburned peat possesses a similar property, and where accessible, is a valuable manure for sandy and calcareous soils, to which it imparts an increased power of retaining moisture. Ashes are often useful. Those of wood, peat, and weeds, yield a considerable amount of the salts of potash. Sea-weeds form a useful manure for many crops, especially flax and hemp. One load of sea-weed is considered equivalent to about four of farm-yard manure. Lime acts in various modes. It yields direct nourishment to vegetation; it promotes the decomposition of organic matter; it liberates silica from some of its combinations; and decomposes and renders insoluble any salts of iron. Wherever the drainage of the land deposits, on exposure to the air, a yellowish-brown ochreous scum, a very liberal application of lime is requisite. It should never be used along with or shortly after guano, blood manures, soot, or ammoniacal salts. Lime is rendered more valuable if slaked with brine

instead of water. Common salt and sulphate of soda in moderate doses are beneficial to rape, colza, cabbages, turnips, and also to the potato. The amount should not exceed $1\frac{1}{2}$ cwt. per acre. Granite roasted in a reverberatory furnace with lime is a valuable dressing for vineyards and tobacco grounds, on account of the potash which it yields. Sulphate of iron, commonly called copperas, ordinarily renders lands barren, but under peculiar circumstances it has had, in small quantities, a salutary effect upon vegetation.

Manures, like the food and medicines given to animals, require to be administered with judgment. Those intended to ameliorate the texture of the soil and effect any kind of decomposition in its ingredients should be added a considerable time before the ground is planted, in order that they may have full scope to perform their function. Rich nitrogenous manures, especially if volatile, should be given only when moisture is plentiful, and when a vigorous vegetation can at once appropriate the nourishment placed at its disposal. To dress the land with guano, sulphate of ammonia, or soot, in dry windy weather is utter folly. The richer manures when administered to growing crops are best given in a state of solution. They are thus presented at once in an available form to the fibrils of the roots, and are secured against lying useless upon the soil. In no other method can grass lands be so efficiently top-dressed. It must, however, be admitted that the use of liquid manures is better adapted to a dry climate than to Britain, where in ordinary seasons the amount of rain bears an excessive proportion to the temperature.

The prepossession of agriculturists in favour of manures which benefit the land for several successive seasons, is, commercially speaking, a mistake. The sooner the farmer gets back a return for his outlay upon manure the better. Instead of spending a large sum upon some manure the returns from which will be spread over a period of three or four years, it is surely better for him to spend annually a smaller sum, and receive his total return thereupon in the same season.

It is a matter of national reproach that even in the present day an immense quantity of the elements of fertility are allowed to go to waste, and even to become nuisances. The Chinese, whom we despise, are so careful of everything capable of acting as manure that they even collect the cuttings of their hair and beards. It may startle the unreflecting to find that the hair-cuttings and nail-parings of our population, which are generally burned, are equal in annual agricultural value to more than 200,000 tons of farm-yard manure.

MANURING, in Horticulture, requires to be viewed in a different light from the same process as applied to agricultural purposes. The species which the farmer cultivates are few in number, whilst the gardener has to deal with many hundreds from the most different climates. Many of the kinds he plants, besides, are perennial, so that he cannot take advantage of the principle of rotation. Hence, from the greater complication of the subject, the application of chemistry to gardening is incomparably more difficult, and brilliant results are obtained apparently in defiance of theory. Thus though the division of plants into classes in accordance with the specific

character of the nourishment they require must hold good in the garden as well as in the field, yet we find composts recommended for different flowers by florists of skill and eminence, in which these distinctions are totally ignored. In fact, the mechanical texture, rather than the chemical composition of the soil, is the main object of the gardener. Porosity, the power of condensing air and watery vapour, together with the inability to retain stagnant water and to bake into a stiff mass, are the properties at which he aims. This he effects in a majority of cases by a liberal use of *loam*. This substance is not the mixture of sand and clay which the farmer understands by the same name. It consists of sods from an old pasture, piled up in heaps, and allowed to remain until the more active phase of putrefaction is over. Of course it contains a large amount of matter in a merorganic, or semi-organized state. Other ingredients used along with, or instead of loam, are the mould resulting from the decay of leaves, heath mould, peat, and cocoa fibre. It can scarcely, however, be doubted that if the florist were, in addition to his care for the texture of the soil, to attend to its chemical composition, he would achieve results still more splendid. This to some extent is already done. We have heard of cultivators of roses who find great advantage from supplying their favourites with lime. The success of the Dutch as cultivators of bulbs arises in part, doubtless, from the fact that their soils are impregnated with salts of soda, resulting from the reaction of sea-water upon the matter brought down by the rivers.

Guano, soot, soap-suds, the sulphate and nitrate of ammonia, soda-ash, and other chemicals, are not unfrequently used in the garden with satisfactory results. Occasionally, however, failures of an unexpected nature occur. Thus the superphosphate of lime, so beneficial to the turnips as a field crop, is found totally useless if applied to early turnips in the garden. Stone-fruits and conifers are injuriously affected by animal manures, or in fact by any kind except decayed leaves. Lime in every form is most pernicious to heaths, rhododendrons, azaleas, &c. The orchidaceous plants, which derive a great part of their support from the atmosphere, seem totally indifferent to all manures that have yet been tried.

Horse-dung mixed with straw is still a favourite manure for many crops, but it is generally used in a very advanced state of decay. For plants which require the maintenance of moisture about their roots, such as the pansy, cow-dung is preferred. From its very fine state of subdivision, like all organic matter when similarly comminuted, it has great powers of retaining and absorbing moisture. The excrements of swine are not recommended as manure. They impart an offensive flavour to fruits and to certain of the choicer vegetables, and in some manner not thoroughly understood, they favour the multiplication of noxious insects. Common salt, ammoniacal salts, and lime, have the opposite effect. Guano and blood manures cannot be safely used except in a walled garden, as the smell attracts dogs, which do great damage by scratching in search of supposed carrion.

It is commonly supposed that the object of the gardener should be, by skilful manuring, to furnish every plant with a soil resembling that in which it naturally grows. This principle, as shown by Dean

Herbert, is in some cases fallacious. Certain species may grow in a poor soil, not from preference, but from necessity, having been driven from more genial localities by rampant and vigorous rivals.

MANUSCRIPTS (Lat. *manu scriptus*, 'hand-written'), literally, writings of any kind and on any material, but generally restricted, in a literary sense, to the books written on vellum before the introduction of the art of printing. Of Latin MSS. those prior to the age of Charlemagne (800) are considered ancient. *Illuminated Manuscripts* are those which are decorated with colours, ornaments, and emblematical figures; a practice introduced at a very early period, but chiefly employed in the missals, breviaries, and other books of devotion of the early Christian church. Among the last examples of illuminated manuscripts executed in this country was Cardinal Wolsey's Lectionary, at Christ Church, Oxford.

MANUZIO, THEOBALDO (Aldus Manutius), born in 1447 at Bassiano in the Papal State, studied at Rome and at Ferrara. He became intimate with Pico, count of Mirandola, and with Alberto Pio, lord of Carpi, with whose assistance he established a printing press at Venice. Manutius surpassed all other printers of his time in the correctness of his books. Being a man of learning as well as a printer, and having an extraordinary zeal for his profession, he procured the most correct MSS., and established an academy in his house, with the view of obtaining assistance in the superintendence of his publications. Bembo and Navagero were among the members of that society. The first publications of Manutius appeared about 1490; the first with a date in 1494. He invented a new sort of type, which was light and resembled writing, called by the Italians 'corsivi,' and known to other nations by the name of 'Italic.' In this type he printed the Latin classics. He was the author of a Latin and Greek Grammar, a Greek and Latin Dictionary (the first of its kind), and several other works. His son Paolo, a man of learning, an author, and a critic, succeeded him in the direction of his printing establishment.

MANZANARES. [CASTILLA-LA-NUEVA.]

MANZANILLA. [MEXICO.]

MAORIS, or MAORIES, the aboriginal inhabitants of New Zealand. The name is derived from a native word signifying 'native' or 'indigenous,' and was first used by themselves. They belong to the Malay race, and have a tradition that their progenitors migrated from the island of Hawaiki, supposed to be the modern Hawaii, in the fourteenth century of our era. But as this island is 4000 miles distant from New Zealand, and the canoes which they used must have been of a rude description, some persons have thought that the tradition alludes to Savaii, one of the Navigators' Islands, a much nearer group. Although the native tradition makes no mention of any previous inhabitants in New Zealand, it is generally believed that the original natives were a darker race, similar to the Papuas of New Guinea, and that in process of time the two races intermingled.

The Maoris are altogether different from the aborigines of the Australian continent, being a fine, well-formed, tall, and muscular people, with a complexion which varies in shade from an olive, or copper-coloured hue, to a dark brown. Their countenances,

especially those of the higher orders, are often very pleasing, and nearly always striking, animated, and intelligent; their hair glossy, black, and curling; and their general cast of features not materially different from the European standard. Few of them have beards or whiskers, as a very old custom exists amongst them of plucking out the hair on their face with shells. The women are of less stature, and altogether inferior to the men. They marry early—some have become mothers at eleven years of age—and perform a large amount of field labour, and thus become bent and old at forty, and weird and witch-like at sixty.

The New Zealanders possess many qualities superior to those of savage nations in general. They have considerable forethought and vigour of mind, and are hospitable, frank, generous, and keenly sensitive upon points of honour. They have, however, the vices as well as the better qualities of the savage; their passions are easily roused, and in the pursuit of revenge their bearing is marked by ferocity and cruelty. When first visited by Europeans, and even until within a comparatively recent period, they were addicted to cannibalism, drinking the blood of their enemies, and feasting with avidity on their remains, baked in ovens scooped in the earth. The last known act of the kind took place in 1843, and the Maoris are now for the most part converted to Christianity. They readily adopt such of the habits and pursuits of the European settlers as appear conducive to their own immediate advantage. In some districts they have considerable tracts of land under cultivation, and bring their produce to the market as regularly as the peasants of other lands. They also make good sailors and fishermen, but, as a rule, will not work very hard; and many still preserve the habits of barbarous life, and continue to reside in wretched hovels, glo clothed in blankets full of vermin, help themselves to food with their fingers, and in short, retain many of the most repulsive features of a savage race. They are divided into tribes, each under its own head or chief, and its members are bound together by a sort of clannish attachment. Their native paha, or villages, are extensive collections of huts, often strongly fortified with palisades.

Formerly the practice of tattooing the body was almost universal, but it has been abandoned since their conversion to Christianity. It was a very painful operation, performed with a hammer and saw-like chisel. The patterns represented ornamental scrolls and figures, to denote the rank of the individual wearing them. The punctures were stained with indelible vegetable dyes, and made the face present a most hideous appearance, although it was supposed to make the Maori youth more prepossessing in the eyes of his mistress.

Infanticide was also formerly prevalent, but is now entirely abolished. The natives are, however, rapidly decreasing in numbers, and are almost entirely confined to the northern island. Altogether they now comprise only about 50,000, their recent contests with the colonists having had the effect of materially decreasing their numbers. In their former wars they used spears and clubs, but of late have become very expert in the use of fire-arms.

Their language belongs to the Malay family, and

seven different dialects are spoken. It is rich and sonorous, and well adapted for poetical expression, especially of the lyrical kind. They have many proverbs, legends, and traditions, and a collection of them was made by Sir George Grey, recently governor of New Zealand.

MAP (in Latin, *mappa*, 'a cloth;' in French, *mappemonde*, 'a map of the world.')

A map is the representation of the surface of a sphere, or a portion of a sphere on a plane. The name however is commonly applied to those plane drawings which represent the form, extent, position, and other particulars of the various countries of the earth.

Maps, being plane representations of the surface of a sphere, may be obviously applied to various purposes; hence we not only have terrestrial maps to represent the surface of the earth, but celestial or astronomical maps to represent the sphere of the heavens; and these general distinctions have again their subdivisions.

There are two kinds of terrestrial maps—geographic or land maps, and hydrographic or sea maps: the latter are usually called CHARTS.

The methods adopted in the construction of maps are as various as the taste and judgment of geographers themselves, but they may all be referred to two principles, viz. *Projection* and *Development*.

By *Projection* is meant the representation of the surface of a sphere on a plane, according to the laws of perspective. By *Development* is to be understood the unfolding or spreading out of the spherical surface on a plane. This, however, first supposes the sphere to be converted into a cone or a cylinder; these being the forms, portions of which most resemble portions of a sphere, and which, at the same time, are susceptible of the required development.

There are three methods of spheric projection in general use, the *Gnomonic* or *Central*, the *Orthographic*, and the *Stereographic*, distinguished from each other by the different positions of the projecting point in which the eye is supposed to be placed.

Projection.

The *Gnomonic* or *Central Projection* supposes the eye to be placed in the centre of the sphere, and that the various objects to be delineated are transferred from a sphere to a plane, which is a tangent to its surface. The entire hemisphere can never be represented by this projection, since the circumference which terminates it is on a level with the eye, and is therefore parallel to the plane of projection. This method is chiefly used in dialling, but may be advantageously applied to maps of a limited extent, more especially if they are maps of the polar regions of the globe. In this case the meridians will be straight lines radiating from the centre, and the parallels of latitude concentric circles, whose distances from the centre will respectively be equal to the cotangents of their latitudes.

In the other cases of this projection, where the perspective plane is parallel to the horizon, or to any meridian, the construction is rendered troublesome on account of the parallels of latitude becoming curves of difficult delineation: these cases therefore are seldom brought into use.

Orthographic Projection.—In this projection the

eye is supposed to be at an infinite distance, so that the visual rays leave the sphere in parallel lines. The perspective plane on which a hemisphere is supposed to be delineated is the plane of that diameter which is perpendicular to the visual rays—hence

every point of the hemisphere is transferred to this plane by perpendiculars let fall upon it. It will be immediately seen from the figure, that the representation will decrease in accuracy with the increase of distance from the centre; the parts near the circumference being much foreshortened and distorted.

In a *Polar Map* of this projection, the meridians, as in the *Gnomonic* maps, will be radii, and the parallels concentric circles; these circles, however, will have their distance from the centre equal to the cosines, and not to the cotangents of their respective latitudes.

In an *Equatorial Map*, or one in which the equatorial regions of the globe are made to occupy the centre of the map, the plane of projection coincides with the plane of one of the meridians. In this case the latitude circles will be projected in straight lines parallel to the equator, which is also a straight line, and will vary in distance from it according to the sines of their respective latitudes. The meridians will be portions of ellipses intersecting the equator in points similar in position to the intersecting points of the parallels on the polar diameter, and having

their transverse axes coincident with this diameter and equal to it.

Stereographic Projection.—In this projection the eye is supposed to be placed at the surface of the sphere, and to view the concave of the opposite hemisphere through the plane of that circle, in the pole of which the eye is placed.

If E be the eye, and A, G, C, the hemisphere to be represented, A, B, C, D, will be the plane of projection; and the position on this plane of any point of the spherical surface will be indicated by a line drawn from that point through the plane to the eye. Thus the points K, L, M, N, on the sphere, will be transferred to the plane at k, l, m, n.

The advantages offered by this method of projection have brought it more into use than the methods before mentioned. It is especially calculated for maps of the world, as usually made in two hemispheres, from the circumstance of the representation being less distorted, and also on account of the meridians and parallels intersecting each other at right angles, as they do on the globe. Its construction also is less difficult than others, since all the great circles of the sphere are either circles or straight lines in the projection. The meridian of 20° W. is the one usually selected by English geographers for the plane of projection in these maps of the world, because this meridian passes very nearly between the eastern and western continents, which therefore occupy their respective hemispheres.

Projection by Development.

The developments to be mentioned are two—the *Conical* and *Cylindrical*.

Conical Projection.—In this projection the sphere is supposed to be circumscribed by a cone, which touches the sphere at the circle intended to represent the middle parallel of the map. If the points on the sphere be now projected on the cone, by lines drawn from the centre, it is clear that in a zone extending but a short distance on each side the middle parallel, as the zone $a' a' b' b'$, the points on the cone would very nearly coincide in position with the corresponding ones on the sphere. All the delineations having been thus made, the cone is then conceived to be unrolled or developed on a plane surface.

Should the map be made to extend much above or

below the middle parallel, the distant parts will be very much distorted. To remedy the defects of this projection, various modifications have been suggested,

among which those of Flamsteed are generally held in the highest estimation.

Cylindrical Projection.—From what has been said of the cone, it will be easily understood that a cylinder may be applied to the sphere in a similar manner, and that a zone of a very limited extent in latitude may, without very material error, be developed on a cylinder. The peculiarity of this method is, that the meridians, as well as the latitude circles, are projected in parallel straight lines; a condition of the map which makes it very applicable to nautical purposes, and on which is partly founded the very ingenious method called *Mercator's Projection*, now universally adopted in our charts, and to which, in conclusion, we will briefly allude.

Mercator's Projection.—The line on which a ship sails, when directing her course obliquely to the meridian, is on the globe a spiral, since it cuts all the meridians through which it passes at equal angles. This circumstance, combined with others, rendered a map constructed on the principles of the spherical projections very inadequate to the wants of the navigator. Mercator considered, very justly, that mariners do not employ maps to know the true figures of countries, so much as to determine the course they shall steer, and the bearing and distance of those points or places which lie near their track; and this projection is the result of his efforts to secure to the seamen these desirable ends. The merit of this most useful method is thought by many to be more justly due to Wright; for although Mercator published his first chart in 1556, he omitted to declare the principles on which he proceeded, and his degrees of latitude did not preserve a just proportion in their increase towards the poles. Wright in 1599 corrected these errors, and explained the principles of his improved construction, in which the degrees of latitude on the chart were made to

increase towards the poles, in the same ratio as they decrease on the globe; so that the course a ship steers by the mariner's compass becomes on the chart a straight line; the various regions of the map, however distorted, preserve their true relative bearing, and the distances between them can be accurately measured. (Consult Jamieson, *On Maps*; Malte Brun, *Géographie Universelle*; and De Morgan, *Explanation of the Gnomonic Projection of the Sphere*.)

MAPLE. [ACER.]

MAPLE SUGAR. Sugar obtained by evaporation from the juice of the sugar maple (*Acer Saccharinum*).

MARABOU (*Leptoptilos Marabou*), a species of bird belonging to the order *Grallatores*, or Waders, and family *Ardeidae*, or Herons. It is a native of Senegal, and is chiefly noted for its beautiful light plumes, known as *Marabou feathers*. Its popular name is the Adjutant.

MARACAYBO. [VENEZUELA.]

MARANHAM, SAN LUIZ DO, or MARANHAO, a town and port on the northern coast of Brazil, stands on the north-western coast of the island of Maranhão, in 2° 30' 40" S. lat., and 48° 50' W. long., and has 36,000 inhabitants. The city is the fourth in rank and importance, and the best-built in the Brazilian empire. It is remarkably clean, hospitable, and prosperous. An episcopal palace, college, governor's residence, theatre, hospital, and numerous convents, form the principal public buildings. There are also a lyceum, and schools of navigation and commerce. The city has a remarkable rainfall, amounting to an annual average of 280 inches. The harbour is defended by two forts, and is of easy access for small vessels. The imports consist of wine, brandy, oil, flour, fruits, silk, cotton and linen goods, hardware and metals, spices, drugs, &c. The exports are cotton, rice, tanned and raw hides, sarsaparilla, &c. The annual value of the imports and exports is each about 300,000*l*.

MARANON. [AMAZON.]

MARANS. [CHARENTE INFÉRIEURE.]

MARANTA'CEÆ, a natural order of endogenous plants, distinguished by a single stamen, whose anther has only one lobe; named after B. Maranti, a Venetian botanist and physician. With the exception of the genus *Calathea*, and of *Canna*, which is commonly cultivated under the name of Indian Shot, because of its beautiful flowers, the species included in this order are of small size, and by no means attractive, but the fleshy tubers of some of them abound in starchy matter, which renders them nutritious. All the species are found wild in tropical countries only. About 160 are known to be in existence.

Maranta arundinacea is generally referred to as the plant from which the arrow-root of commerce is obtained, but it is also procured in large quantities from a variety of closely allied plants. Thus the Surinam and Bermuda arrow-root is the produce of the *M. arundinacea*, while the Jamaica arrow-root is obtained from the *M. indica*, which plant, along with several curcumas, yields also the East Indian arrow-root. The West Indian arrow-root has mostly a pure white colour, the East Indian a yellow tinge.

The tubers, root-stocks, or offsets, are grated or bruised, and repeatedly washed with water, which is

passed through a fine hair-sieve so long as it runs off with a milky appearance. It is allowed to subside, the supernatant water drained off, and the powder dried. Arrow-root consists essentially of starch, and potato-starch is frequently used to adulterate it, or as a substitute for it. The grains of the different kinds of arrow-root starch may be distinguished from those of the potato by their form under the microscope.

Arrow-root dissolved in water, milk, or any other appropriate vehicle, constitutes, from its easy digestibility, a most excellent article of diet for delicate persons and young children. It may be given plain, or with wine or spices, according to circumstances. Potato starch may be prepared at a very cheap rate, but is not so easy of digestion as arrow-root.

MARASMUS (emaciation, from Gr. *maraino*, 'I waste away') is a term often used by the older medical writers to designate those cases in which no particular cause for the atrophy of the body was discovered.

MARATEA. [BASILICATA.]

MARATHON, a small plain in the north-east part of Attica, about five miles in length and two in breadth, which is chiefly memorable for the victory which the Athenians under Miltiades gained over the Persians here, B.C. 490. The Athenians who fell in the battle were buried in the plain; and also, but apart from the Athenians, the Plateæans, Boeotians, and slaves. A large tumulus of earth still rises from the centre of the plain; and near the sea there are two others, much lower than the former. The modern Vrana stands on the site of the ancient village of Marathon.

MARATTI, CARLO, was born at Camurano, in the March of Ancona, in the year 1625. He was a highly esteemed painter of the Roman school. He painted for Louis XIV. his celebrated picture of 'Daphne.' Fuseli considers 'Bathsheba viewed by David,' his greatest work. He died at Rome in 1713.

MARAZION. [CORNWALL.]

MARBLE (Lat. *marmor*). A strict definition of this term is perhaps impracticable, unless, with Da Costa, we limit it to the calcareous rocks, 'of very lively colours, and of a constitution so fine that they will readily take a good polish.' A limestone which will admit of being worked equally in all directions, and is capable of taking a good polish, deserves the title of marble; when it is granular and of a white colour, it may be useful in statuary.

The following are brief notices of some of the best known and most useful marbles:—

Division I. Marbles of One Plain Colour.

Section 1. Black marbles. Most of these contain bitumen, and are fetid when bruised. Examples. The Namur marble, the marble of Ashford in Derbyshire, Dent in Yorkshire, near Crickhowell, Tenby, Kilkenny, &c.; the marble anciently called Marmor Luculleum, and now Nero Antico.

Section 2. White marbles. Examples. The marble of Paros; the Carrara marble, of finer grain, much used in modern sculpture; the Skye marble, that of Inverary, Assynt, Blair-Athol, &c.

Section 3. Ash and gray marbles. Example. A beautiful marble, of compact oolitic texture, at Orleton, near the Cleve Hills in Shropshire.

Section 4. Brown and red marbles. Examples. The Rosso Antico; a marble on the estate of the duke of Devonshire, near Buxton. The mottled brown marble of Betham Fell, near Milnthorpe, is of good quality. Mandelato, light-red, veined, and clouded.

Section 5. Yellow marbles. Examples. The Giallo Antico; Siena marble. That used in ancient Rome is said to have been from Numidia.

Section 6. Blue marbles. Example near St. Pons in Languedoc.

Section 7. Green marbles. Examples. The Marmor Lacedæmonicum of Pliny; it is dug near Verona. Irish green marble.

Division II. Marbles of Two Colours.

Section 1. Black marbles variegated with other colours. Examples. Near Ashburton and Torbay, in Devonshire; Bianco e Nero Antico, the African Breccia of the ancients; Giallo e Nero Antico.

Section 2. White marbles variegated with other colours. Example. Marble imported from Italy. Marbles of this general character occur at Plymouth, at Killarney, in Sweden, &c.

Section 3. Ash and gray marbles variegated with other colours. These are very numerous, and occur in various parts of Europe.

Section 4. Brown and red marbles variegated with other colours.

Section 5. Yellow marbles variegated with other colours.

Section 6. Green marbles variegated with other colours. Examples. Egyptian marbles—the Marmor Tiberium and Augustum of Pliny; some Verde Antico, as that dug near Susa in Piedmont; the beautiful marble of Anglesey (called Mona marble).

Division III. Marbles variegated with Many Colours.

Examples. Some of the Plymouth marble; the beautiful Brocatello or Brocade marble of Italy and Spain.

Marbles containing Shells, Corals, and other extraneous Bodies.

In this division of marbles the British Islands are rich. Some of the Plymouth, Ashburton, and other Devonian limestones are extremely beautiful, from the abundance of fine corals exquisitely preserved in them; the Crinoidal marbles of Flintshire, Derbyshire, and Garsdale in Yorkshire, are elegant examples of the carboniferous limestone; the shell marbles of Buckingham, Whichwood Forest, Stamford, Yeovil, may be noticed, from the oolitic rocks. That of Petworth and Purbeck, from the Wealdon strata, has been extensively used by the architects of the middle ages.

MARBLEHEAD. [MASSACHUSETTS.]

MARBURG, the capital of the province of Upper Hesse, in the electorate of Hesse-Cassel, is most beautifully situated in 50° 50' N. lat., 8° 47' E. long., on the Lahn, and on the railway to Frankfort, 48 miles S.W. of Cassel. Population in 1861, 7689. The town, which is partly surrounded with a wall pierced by five gates, has a university, with a library of 100,000 volumes, an anatomical theatre, a chemical laboratory, a botanical garden, &c. The university was founded in 1527, and has had among

its students Patrick Hamilton and William Tyndale, translator of the English Bible; it has now forty professors, and an average of 300 students. The church of St. Elizabeth, in the Pointed Gothic style, deserves notice; and there are besides many hospitals. Manufactures of linens, stockings, and leather, are carried on, and there are also extensive potteries and tanneries.

MARCA D'ANCONA, an old denomination of a geographical division of the kingdom of Italy. It has been called La Marca, 'the March,' since the time of the Carolingian emperors and kings of Italy, from being governed by marchiones or marquises. *March* meant originally a frontier district, but the term was afterwards applied rather capriciously. Cæsar Borgia subdued the country, and it became from his time annexed to the papal territories. It was then generally called Marca d'Ancona, from its principal town; but the south-east part of it was also sometimes called Marco di Fermo, and the two together were often designated Le Marche or the Marches.

MARCELLINUS. [AMMIANUS MARCELLINUS.]

MARCELLINUS was bishop of Rome in the reign of the Emperor Diocletian. He died in 304.

MARCELLO, BENEDETTO, a patrician of Venice, son of Agostino Marcello, a senator, was born in 1686. He studied music under Gasparini and Lotti, and in 1716 a serenata from his pen on the birth of the first son of the Emperor Charles VI. was performed at Vienna. His great work, published in eight volumes, folio, in 1724 and 1726, was 'Estro Poetico-Armonico, Parafrasi sopra i 50 primi Salmi. Poesia di G. A. Giustiniani, Musica di B. Marcello, Patrizi Veneti.' It is of high excellence, and the music was adapted to our translation of the Psalms by Mr. Garth, organist of Durham. Marcello composed many other works, but few have survived. He died in 1789.

MARCELLUS, MARCUS CLAUDIUS, born of a Roman consular family, after passing through the offices of ædile and quæstor, was made consul, B.C. 222. At the beginning of the second Punic war, Marcellus was sent to Sicily as prætor to administer the Roman part of the island, and to keep the Syracusans firm to their alliance with Rome. After the battle of Cannæ he was recalled to Italy, to oppose Hannibal. He took the command of the relics of the Roman forces in Apulia, kept Hannibal in check, and defended Nola. In the year 214 B.C., being again consul, he took Casilinum by surprise. He was next sent to Sicily, where Syracuse had declared against Rome. After a siege of nearly three years, the town was taken in the year 212 B.C., when Archimedes, the great mathematician, lost his life on the occasion of this taking of Syracuse. In the year 210 B.C. he was again chosen consul, and had the direction of the war against Hannibal in Apulia, in this and in the following year. In B.C. 208 Marcellus was elected consul for the fifth time. He continued to carry on the war against Hannibal, when being encamped near Venusia, he fell into an ambuscade and was killed. Hannibal caused his body to be buried with honours. He was one of the most distinguished Roman commanders during the second Punic war, and had the honourable reputation of being a disinterested man.

MARCELLUS I. II. [POPE.]

MARCGRAVACEÆ, a natural order of Petaloid exogens, having an imbricated calyx, numerous hypogenous stamens, and a superior ovary with a discoid stigma and many polyspermous cells. They are all inhabitants of the tropical parts of America, and are usually scrambling shrubs, which are sometimes true parasites. The order is of no known use, and of but little interest, except in a systematical point of view; unless for the sake of its very curious bracts, which vary in form in different species, but which are more or less usually pitcher-shaped.

MARCH, the third month of the year according to modern computation, containing thirty-one days. The Roman year originally began with March; and in England, before the alteration of the style, the legal year commenced on March 25. The name of the month is said to be derived from that of Mars, the god of war.

MARCH, in Music, is, properly speaking, an air in double time, played by martial instruments, to mark the steps of the infantry, as well as to amuse and cheer troops of all kinds. It has, however, long since gained admission into sacred as well as into operatic musical compositions, as, for instance, the marches in Handel's oratorios; the religious marches in Gluck's 'Alceste,' and Mozart's 'Zauberflöte;' the two funeral marches of Beethoven, &c.

MARCH. [CAMBRIDGESHIRE.]

MARCHANTIACEÆ, a small natural order of Acrogens or cryptogamic plants, forming part of the old group called *Hepaticæ*. They are plants of a low organization, in most instances having no distinction of leaves and stem, but a thin, leafy, lobed thallus in their room, in which respect they resemble lichens; but are furnished with breathing pores and an approach to spiral vessels in the form of elaters, which latter circumstances elevate them to the level of *Lycopodiaceæ* and *Marsiliaceæ*.

Marchantiaceæ differ from *Jungermanniaceæ*, with which they were formerly combined under the old name of *Hepaticæ*, in not having a distinct stem, and in their fruit not being four-valved. *Marchantia* itself, a common plant under the north side of old walls and hedges, upon damp ground, forms deep green patches with a lobed lichenoid thallus, and has reproductive organs of two kinds arranged separately below mushroom-shaped heads.

MARCHE, LA, one of the old provinces into which France was divided before the Revolution, was bounded N. by Berri, E. by Auvergne, S. by Limousin, and W. by Poitou and Angoumois. It now forms the department of Creuse, and parts of Indre, &c.

MARCHES (Anglo-Saxon, *mearc*, 'a boundary'). *Mark* is a word common to almost all the languages of Teutonic origin, in sense scarcely varying from the word as at present used, a *mark*. But from denoting a mark in general, it came to denote in a specific and peculiar sense those important marks by which the boundaries of wide domains were indicated, and in this sense it is found in Anglo-Saxon writings. Hence the words *The Marches*, that is, the country lying near and about the *marks* which indicated the limits of two kingdoms, dukedoms, or other extensive jurisdictions.

The word is used in Germany, and upon it is founded one of their titles of honour, the *markgraf* (*margrave*), or lord of the marches; and our own

marquis is of the same origin. The Marches of Wales and of Scotland was a term in use in our history until the union of those countries with England.

MARCIANUS, born in Thrace, of obscure parents, towards the end of the fourth century, entered the army, rose gradually by his merit to high rank, and was made a senator by Theodosius II. When Theodosius died in 450, his sister Pulcheria, then fifty-two years old, offered her hand to Marcianus, who was near sixty, because she thought him capable of bearing the crown with dignity and advantage to the state. Marcianus married her, and was proclaimed emperor. His reign, which lasted little more than six years, was peaceful, and his administration was equitable and firm. He died in 457.

MARCIENNES. [NORD.]

MARCIONITES, a religious sect of the second and third centuries, so called from their teacher Marcion, who adopted the old Oriental belief of two independent, eternal, co-existing principles, one evil and the other good. He endeavoured to apply this doctrine to Christianity. The Marcionites spread far in the East, and especially in Persia. The chief opponent of Marcion was Tertullian, who wrote a book to refute his doctrines.

MARDIN, a town of Northern Mesopotamia, built on a steep hill forming part of the chain that divides the basin of the Upper Tigris, or country of Diarbekr, from the plains of Sinjar, which are watered by the affluents of the Euphrates. Mardin is a considerable though poor town; two-thirds of the inhabitants are Moslems, and the rest Christians, with some Jews. Mardin has eight mosques, several bazaars, and some public baths. The castle, on the summit of the hill above the town, is strong by its situation. The town of Mardin is nearly half-way between Diarbekr and Mozul, and on the road from Constantinople to Bagdad.

MAREMMA, the name given to the unwholesome lowlands which extend along the Mediterranean coast in Tuscany and the Papal States. The Tuscan Maremma begin N. of Lucca, and extend, with but few interruptions, from the approach of the highlands to the sea, as far as the mouth of the Pescia, which river divides Tuscany from the Papal States. They stretch inland generally from 10 to 12 miles. The Roman Maremma begin at the Pescia, and extend as far as Terracina on the Neapolitan frontier, a length of above 120 miles, with a very unequal breadth inland, owing to the approach of various offsets of the Apennines to the sea. The whole of this tract is low and unimproved, and whether the surface be marshy or dry, it is unwholesome, especially in summer. Of late years special attention has been directed to the drainage and amelioration of the Tuscan Maremma, and considerable success has attended their being largely planted, as trees are a corrective of their malarious effects.

MARENGO, or **MARENGO-SPINETTA**, a village in Piedmont, on the right bank of the Bormida, and in the immediate vicinity of Alessandria. Here was fought the great battle, June 14, 1800, between the French, under Napoleon, and the Austrians, under General Melas, ending in the total defeat of the latter, with immense loss. At one time the victory was in the hands of the Austrian commander, but, aged and fatigued, he neglected to pursue his advantage, and

gave Napoleon time to bring up his reserve, under Desaix, whose splendid and vigorous charge decided the fortune of the day. Desaix, shot through the head, fell at the first fire, but the French pushed on and literally drove the Austrians into the Bormida. A museum, and a monument to the memory of Napoleon, were erected on the battle-field in 1847, by M. Giovanni Delavo.

MARENNES. [CHARENTE INFÉRIEURE.]

MARENZIO, LUCA, a voluminous and excellent composer of madrigals, was born at Concaglia in Brescia about the middle of the sixteenth century, and died at Rome in 1599. Handel and Purcell, as Dr. Burney remarks, did not disdain to become his debtors.

MAREOTIS, Lake. [ALEXANDRIA; EGYPT.]

MARGARET OF ANJOU. [HENRY VI.]

MARGARIC ACID, a fatty acid, so called by Chevreul, who discovered it, from *margaron*, (*μαργαρον*), 'a pearl,' on account of its peculiar lustre. It is prepared from soap made with olive oil and potash. It crystallizes in pearly needles; it is insoluble in water. It has an acid reaction; and its salts, except those of the alkalis, are very sparingly soluble in water. Its saline compounds are termed *margarates*. According to Berzelius, it consists of O^3 , H^{33} , C^{35} . Melts at 140° .

Margarate of potash presents the varied forms of brilliant scales, a solution, and a jelly, according to its mode of preparation. The *Bimargarate of potash*, and the *Margarates of soda and of lead*, bear a good deal of resemblance to it.

MARGARIN, a peculiar fatty matter contained in vegetable oils, and also in animal fats, as mutton suet and hog's lard. This substance is very soluble in cold ether, which distinguishes it from stearin.

MARGARITIC ACID, a solid compound of oxygen, hydrogen, and carbon, which, together with *ricinic* and *elaiodic acid*, results from the formation of a soap of castor oil and hydrate of potash.

MARGARITONE D'AREZZO was born at Arezzo about 1215. He was a painter of the Byzantine school, and of great reputation in his day. Most of his works have now perished; but one of his masterpieces, namely, San Francisco, painted for a convent in Sargiano, still exists.

In sculpture, says Vasari, Margaritone was more successful than in painting. There is still by him, in the cathedral of Arezzo, a reclining marble statue of Gregory X. on a monument, which, according to Vasari, is his chef d'œuvre. As an architect, he superintended the building of the cathedral of Arezzo, where he died, aged seventy-seven, and was buried.

MARGARON, a solid white fatty matter which crystallizes in pearly scales, and is obtained by dissolving margaric acid with excess of lime.

MARGATE. [KENT.]

MARIA THEREZA, Archduchess of Austria, Queen of Hungary and Bohemia, and Empress of Germany, born in 1717, was the eldest daughter of Charles VI. of Austria, emperor of Germany. [CHARLES VI.] In 1724, Charles, by the Pragmatic Sanction, regulated the order of succession in the family of Austria, declaring that, in default of male issue, his eldest daughter should be heiress of all the Austrian dominions, and her children after her.

In 1736 Maria Theresa married Francis of Lorraine,

grand duke of Tuscany. Upon the death of Charles VI. in 1740, the king of Prussia, the elector of Bavaria, the elector of Saxony, and the kings of France, Spain, and Sardinia, agreed to dismember the Austrian monarchy, to parts of which each of those powers laid claim. Maria Theresa, in spite of the threatened encroachments of those powers, supported by the enthusiastic efforts of the Hungarians, to whom she appealed, made good her claim as empress. She drove the French and Bavarians out of her kingdom. Her political acts are worthy of record. She abolished the torture, commuted the services which the Bohemian peasants owed to their feudal superiors, put a stop to literary piracy, established a national system of education, and made several important reforms in the temporalities of the clergy. She will ever rank among illustrious women and the benefactors of mankind. She died at Vienna, November 29, 1780.

MARIANA, JUAN, was born at Talavera in 1536. At the age of seventeen he joined the Jesuits, and devoted much study to theological subjects; but is best known for his 'History of Spain,' which has been translated into English by Stevens. The profound erudition of Mariana is also displayed in his 'Tractatus Septem,' Cologne, 1609. At the age of eighty-three he published his 'Scholia' on the Old and New Testaments, availing himself of the best Hebrew commentaries, and some valuable and very early MSS. which dated from the age of the ancient Gothic dominion in Spain. He died at Toledo, February 6, 1623.

MARIE ANTOINETTE, born at Vienna, November 2, 1755, was the daughter of Francis of Lorraine, emperor of Germany, and of Maria Theresa of Austria. In May, 1770, she married Louis, the dauphin, grandson of Louis XV., who in 1774 became king of France, under the name of Louis XVI. When the Revolution began, Marie Antoinette was on the side of the more resolute aristocratic leaders, and would have opposed it vigorously. She was one of the advisers of the attempted flight of the king, which proved unsuccessful, and only served to excite the public animosity against her and her husband. During the various attacks made against the royal family, she showed great courage. Her demeanour under the most trying circumstances never lost its dignity. After the death of her husband, she seemed for a time forgotten in the prison of the Temple; but she was brought to trial before the revolutionary tribunal October 14, 1793, found guilty, and condemned to death. In the presence of her judges, the burst of indignant maternal feeling with which she appealed to any mothers present, when an infamous and absurd charge was brought against her, overawed even her accusers.

On October 16, 1793, she was removed in a common cart from the prison of the Conciergerie to the place of execution. On her way she was reviled and abused by the ferocious mob in the most unfeeling manner, but appeared heedless of their vociferations, and suffered death with firmness and composure. She was thirty-eight years of age, but owing to her sufferings she bore a much older appearance. She left one son, who died in prison (Louis XVII.), and a daughter, the late duchess of Angoulême.

MARIE-AUX-MINES. [RHIN, HAUTE.]

MARIE DE' ME'DICI, the daughter of Francis I., grand duke of Tuscany, and of the archduchess Joan of Austria, was born in Florence in 1573, and was married in 1600 to Henry IV. of France. Her unhappy temper led her to quarrel with her husband, and subsequently with her son. She was at last exiled for her political intrigues, and died at Cologne, in 1642, almost destitute.

MARIE-GALANTE, an island in the Caribbean Sea, about 15 miles south of Guadeloupe, of circular form and about 14 miles in diameter, was discovered by Columbus in 1493, and first settled by the French in 1647. The surface is of moderate elevation, and rises gradually towards the north; the western coast is low. The soil is productive, and yields abundantly the several West-Indian products. The population in 1861 was 12,000.

MARIENBURG. [DANZIG.]

MARIENWERDER, one of the governments into which the province of West Prussia is divided, is bounded N. by the government of Danzig, E. by that of Königsberg, S. by Poland and Posen, and W. by Brandenburg. Its area is 6759 square miles, and the population in 1862 was 712,831. The government is divided into thirteen circles.

Marienwerder, the capital, situated on the Liebe and the Little Nogat, 2 miles from the Vistula, over which there is a pontoon bridge 2700 feet in length, has 6607 inhabitants. It has a cathedral, with a steeple 170 feet in height; schools of art and agriculture, and an hospital for blind soldiers. It is the seat of the provincial courts and the government offices. There are manufactories of woollens, hats, soap, and leather. The breweries and distilleries are very considerable. The town is one of the most beautiful and prosperous in West Prussia. The other towns are—*Thorn*, the birthplace of Kepler and Copernicus, which is a fortified town on the Vistula, here crossed by a long bridge, and has 10,000 inhabitants. The extensive fortifications of this place have been greatly improved since 1815. *Culm*, or *Kulm*, also on the right bank of the Vistula, with a population of 6300, and some cloth factories. *Graudenz*, which also stands on the right bank of the Vistula, here crossed by a bridge of boats, and has, including the military, 10,100 inhabitants, who manufacture woollen cloths and tobacco, and trade in corn. The town is surrounded by a wall, and defended by a strong fortress which commands the course of the Vistula.

MARIGOLD. [CALENDULA.]

MARINE FORTIFICATIONS. In the article FORTIFICATION the different kinds of land fortifications have already been described. Those constructed to repel the attacks of vessels are somewhat different in principle, as there are generally no intervening obstacles to overcome, and the struggle is chiefly a question of strength. The principle generally adopted is to construct the fortress with as little exposed surface as possible, as it is so much the less likely to be struck from the vessel. The walls are generally perpendicular, and wherever it can be done, the structure is made bomb-proof. The most simple sea fortresses are mere parapets in the side of a hill, and if possible, concealed from the observation of vessels at sea. These fortifications are numerous all round the British coast, as are also the MARTELLO

TOWERS, which latter, however, are not now considered of much use. But the most important sea fortresses are the beach forts at Portsmouth, sweeping the very surface of the water, and especially the exceedingly strong isolated forts, with perpendicular faces and several tiers of guns, as at Spithead, Plymouth, and Cronstadt. The construction of iron-plated ships has rendered it necessary to mount sea fortresses with the very heaviest and most powerful guns, and even then those vessels can sometimes pass them with impunity.

MARINE INSURANCE. [SHIPS.]

MARINER'S COMPASS. [COMPASS, MARINER'S.]

MARINES, men embodied to serve as soldiers on board of ships of war in naval engagements; and on shore, in the event of a descent being made upon an enemy's coast. In the British service they also assist occasionally in performing some of the operations connected with the working of the ship; they cannot, however, be sent aloft at the command of a naval officer.

During the reign of William III. the soldiers placed on the establishment of the navy seem to have been retained as persons in training to become good seamen; and as soon as they became qualified they were discharged from the regiment, and entered on the ship's books as foremast men. In 1775, on the recommendation of Lord Anson, the existing regiments having been disbanded, 130 companies of marines were raised, consisting in all of above 5000 men, and placed under the immediate command of the Lords of the Admiralty. The corps of marines, as it was then called, was subsequently much increased; and during the war at the beginning of this century, its strength amounted to above 20,000 men, exclusive of two companies of marine artillery. At present there are four divisions of royal marine light infantry, and one division of royal marine artillery. The total strength is about 18,000 men. They are commanded by a deputy adjutant-general, who is assisted by an assistant adjutant-general. There are also five colonels-commandant of divisions, and five colonels second commandants. The entire government of the corps rests with the Admiralty. In rank the officers correspond with army officers of similar grades according to seniority. No commissions in the corps are obtained by purchase, and the officers of marines rise by seniority, as high only, however, as the rank of colonels-commandant. The marines are now clothed and armed in the same manner as the infantry of the line. In an engagement at sea, they annoy the enemy by a fire of musketry from the tops and deck; and they repel with the bayonet any attempt made to board the ship. Every man-of-war on being commissioned has her complement of marines drafted into her.

MARINO, SAN. [SAN MARINO.]

MARIONETTES are little figures of men and women, made of either wood or cardboard, and moved by means of cords or springs on the stage of what are called marionette theatres. The person who moves them is concealed from the audience, and alters his voice to suit the different figures, thereby producing a mimic dramatic entertainment. The amusement was known to the ancient Greeks and Romans, and in France and Italy is still practised.

MARIOTTE, EDMÉ. Little is known of his life. He was a Burgundian born, a priest by profession, and resided in the earlier part of his philosophical career at Dijon. He was afterwards prior of Saint Martin, near Beaune, and died May 12, 1684, having been one of the first members of the Academy of Sciences.

MARIOTTE'S LAW, so called from its discoverer, Edmé Mariotte, who died in 1684. It may be defined, in pneumatics, as a general property of elastic fluids viz., that the elastic force is inversely proportional to the space which the fluid occupies. This principle, however, had been previously set forth by our own countryman, Boyle, in 1668, but it does not appear that the work in which he enounced it was known to Mariotte, nor does Boyle express it with the same lucidity and certainty.

MARITIME LAW. [SHIPS.]

MARITZA. [BALKAN; THRACE.]

MARIUS, CAIUS, was born of humble parents at Arpinum, about B.C. 157. He served at the siege of Numantia, B.C. 134, under Scipio Africanus, together with Jugurtha, where he highly distinguished himself. In B.C. 119 he was elected tribune of the plebeians, in which office he showed himself a most determined enemy to the patrician order. He obtained the prætorship with difficulty, in consequence of the opposition of the patricians, who accused him of having used bribery. Marius married Julia, an aunt of Julius Cæsar.

In B.C. 109 he accompanied Metellus into Africa in the capacity of *legatus* (second in command); and by his prudence and courage in the war with Jugurtha he added greatly to his military reputation. His friends at Rome persuaded the people that the war with Jugurtha would never be concluded until the command was given to Marius. Metellus with some difficulty allowed his lieutenant leave of absence to go to Rome in order to stand for the consulship. Marius obtained that dignity (B.C. 107) and the direction of the Jugurthine war. In the following year (B.C. 106) he obtained possession of Jugurtha, who was treacherously given up by Bocchus to his quæstor Sulla. [JUGURTHA.] The news of the defeat of the Consul Manilius, and the Proconsul Cæpio, by the Teutones and Cimbri (B.C. 105), caused the greatest consternation at Rome; and Marius was elected consul during his absence in Africa.

He entered upon his second consulship B.C. 104, and was again chosen consul in the two following years (B.C. 103, 102). In his fourth consulship (B.C. 102), he defeated the Teutones and Ambrones, near Aquæ Sextiæ (*Aix*) in Gaul; and in the following year, B.C. 101, having been re-elected for the fifth time, joined his forces with those of Catullus, and entirely defeated the Cimbri in the plain of Vercellæ (Vercelli) situated to the north of the Po.

Marius was once more a candidate for the consulship for the following year; but the fear of the Gallic invasion was removed, and he was opposed by the patrician party. He nevertheless obtained the dignity, in great part owing to the exertions of Saturninus, the tribune. At the expiration of his consulship he left Rome; but in B.C. 90 the Marsian or Social war broke out, in which Marius and Sulla were engaged as legati to the two consuls.

But disgusted, it is said, with the increasing reputation of Sulla, Marius resigned his command before the conclusion of hostilities.

The Marsian struggle had scarcely been brought to an end, before a war broke out between these two great rivals. The conduct of the Mithridatic campaign had been assigned to Sulla, who was now consul (B.C. 88); but his opponent used every effort to wrest it from him. He was warmly supported by P. Sulpicius, the tribune, and a law was passed that the command should be taken from Sulla and given to Marius. Sulla was with the army at the time besieging Nola; but as soon as he heard of the law, he marched to Rome; and Marius and his adherents were obliged to quit the city. Marius escaped with the greatest difficulty to Africa; but in the following year (B.C. 87), when Sulla had gone to Greece to oppose Archelaus, he returned to Italy, and joined the Consul Cinna, who had been driven from Rome by his colleague Octavius, supported by the patrician party. Marius and Cinna, with the assistance of Carbo, blockaded the city, and as soon as they got possession of it, a general massacre of the opposite party ensued. All the leaders of the patrician party who were unable to escape from Rome were put to death.

Marius and Cinna declared themselves consuls for B.C. 86, without holding the comitia; but Marius died in the beginning of the year. His life has been written by Plutarch.

MARIVAUX, PIERRE CARLET DE CHAMBLAIN DE, was born at Paris, in 1688. He wrote some dramas, but his celebrity rests upon his clever romances. He died at Paris in 1763.

MARJORAM, an aromatic potherb used in cookery, especially among the French. It is the *Origanum majorana* of Linnæus, or *Majorana hortensis* of Moench, a native of Barbary and the Himalaya mountains. In gardens it is little better than an annual; in a wild state it is a suffruticose perennial.

MARK. [MONEY.]

MARK, ST., the Evangelist, is supposed to be the same person as John Mark, who is mentioned in the Acts of the Apostles (xii. 12, 25; xiii. 5, 13; xv. 37). He was the son of Mary, a pious woman at Jerusalem, in whose house the disciples were wont to meet (Acts xii. 12), and the nephew of Barnabas (Col. iv. 10). He left Jerusalem with Paul and Barnabas, about A.D. 44 (Acts xii. 25), and accompanied them in their journey to Antioch, and thence in their mission (Acts xiii. 5), as far as Perga in Pamphylia, where he parted from them and returned to Jerusalem (Acts xiii. 13). About A.D. 53 we find him again at Antioch, when Paul proposed to Barnabas to visit the Asiatic churches. Mark accompanied Barnabas alone to Cyprus (Acts xv. 37-39). There appears to have been some disagreement between Mark and Paul, but they were afterwards reconciled, for we find him at Rome with the apostle during his imprisonment. That Mark was also at Rome with Peter (1 Peter v. 13), is the only other particular concerning him which the scriptures contain. According to Eusebius, Epiphanius, and Jerome, he afterwards went to Egypt, and founded a church at Alexandria, where he died and was buried, according to Jerome, in the eighth year of Nero's reign, A.D. 62. According to an old tradition, he sealed with

his blood his testimony to the truth of the Gospel, and his body was afterwards removed to Venice, of which city he is recognized as the patron saint. But this date appears to fix his death earlier than other circumstances in his history warrant.

The genuineness and authenticity of the 'Gospel according to St. Mark' are attested by the unanimous voice of ecclesiastical writers. Michaelis has indeed objected to its canonical authority, in common with that of Luke, but on no good ground. The time when it was written is uncertain, probably about A.D. 64 or 66.

According to the unanimous testimony of the early ecclesiastical authors, the gospel of Mark was written in Greek, at Rome, and under the instructions of St. Peter.

MARKET, a public place and fixed time for the meeting of buyers and sellers. A legal market can exist only by virtue of a charter from the crown or by immemorial usage, from which it will be presumed that a royal charter once existed, although it can be no longer produced. A market is usually granted to the owner of the soil in which it is appointed to be held, who, as such grantee, becomes the owner, or lord, of the market. In upland towns, that is, towns which, not being walled, had not attained the dignity of boroughs, markets were frequently granted to lords of manors; but in walled towns or boroughs, particularly in such as were incorporated, the ownership of the soil having usually, by grant from the crown, or other lords of whom the borough was originally holden, been vested in the incorporated burgesses, the practice has commonly been to grant markets to the municipal body.

Formerly markets were held chiefly on Sundays and holidays, for the convenience of dealers and customers, who were brought together for the purpose of hearing divine service. But in 1285, by 13 Edward I. c. 5, fairs and markets were forbidden to be held in churchyards; and in 1448, by 27 Henry VI. c. 5, all showing of goods and merchandise, except necessary victuals, in fairs and markets, was to cease on the great festivals of the church, and on all Sundays except the four Sundays in harvest. The holding of fairs and markets for any purpose on any Sunday was prohibited in 1677, by 29 Charles II. c. 7.

It is a rule of the common law (subject to some exceptions) that every sale in market-overt (open market) transfers to the buyer a complete property in the thing sold; so that however defective the title of the vendor may be, that acquired by the vendee is perfect, even where the property belongs to a person who is under legal disability, as an infant, a married woman, an idiot, or a person in prison or beyond sea. In the city of London every shop is market-overt for goods usually sold there. The privilege of market-overt is unknown in the law of Scotland. When, therefore, goods have been sold in open market by one who has stolen them, or by a person to whom they have been lent, the owner may recover them from the purchaser. But corn subject to the landlord's hypothec, if sold in bulk in market-overt, is secured to the purchaser against the operation of the hypothec.

A market is generally appointed to be held once, twice, or three times in a week, for the current sup-

ply of commodities, mostly of provisions. A large market held once or twice a year is called a fair; and, according to Lord Coke, a large fair held once a year is a mart.

Fairs have all the legal incidents of markets, and are subjected to further regulations by 2 Edward III. c. 15, one of which requires, that at the opening of the fair, proclamation be made of the time that it is to continue.

MARKET - HARBOROUGH. [LEICESTERSHIRE.]

MARKLAND, JEREMIAH, was born the 29th of October, 1693, at Childwall, in Lancashire. He was sent to St. Peter's College, Cambridge, in 1710, and became a fellow and tutor of his college. During the latter part of his life he resided in retirement at a small village near Dorking, where he died on the 7th of July, 1776.

Markland devoted a long life to the diligent study of the Greek and Roman writers. He was one of the best English scholars and critics of the last century.

MARL (Dutch, *marghel*, from *margh*, 'marrow,' i.e., to fatten or enrich land), an earthy substance found at various depths under the soil, and extensively used for the improvement of land. It consists of calcareous and argillaceous earth in various proportions, and as the former or the latter prevails, so it is beneficially employed on clays or sands. There are several distinct sorts of marl—clay marl, shell marl, slate marl, and stone marl. The effect of marl is the same as that of clay and chalk upon sandy soils; on heavy soils its effect is proportioned to the quantity of calcareous earth which it contains. The peculiar advantage of marl is its readily crumbling to powder by the effect of air and moisture.

Marl is often found very near the surface, so as to mix with the soil in ploughing; but unless there be a sufficient depth of soil above, its presence does not indicate great fertility. It is generally best when found at a moderate depth, so as to be readily dug out and carted on the adjacent lands. Marl, when put fresh upon the land, requires some time in order to become effective. It should therefore be laid on the surface and spread before winter, leaving it there for a considerable time before it is ploughed in. It is most advantageous to put it on the land when it is in grass, and to roll and harrow it repeatedly, in order to expose it to the effect of the air and rains. Alternate frosts and thaws greatly assist its pulverization.

An excellent use of marl is in forming composts with dung and peat earth. It is laid in layers with the dung and peat, and if the heap is well soaked with urine or the washings of stable-yards, it will in a short time become a most valuable manure for all kinds of soils.

Marl was in common use in England as a manure as early as the thirteenth century, and an Act passed in 1225 gave every man a right to sink a marl pit on his own land. Of late years lime has been often used instead of marl, as, owing to its bulkiness, the latter can only be used in the neighbourhood in which it is found.

MARLBOROUGH. [WILTSHIRE.]

MARLBOROUGH, JOHN CHURCHILL, DUKE OF, was born at Ashe, in Devonshire, on the 5th of July, 1650, of an old cavalier family which had

suffered much in the civil war for its attachment to the royal cause. After receiving the rudiments of education from a Devonshire clergyman, and a brief course of tuition at St. Paul's School, London, he procured, through the influence of his sister Arabella, a favourite of James, duke of York, a pair of colours in a regiment of foot-guards at the early age of sixteen. The charm of his address and his handsome person soon attracted notice in the gay court of Charles II., and insured him a rapid promotion, which, however, was justified by his courage and military capacity. At Tangier, in 1666, he greatly distinguished himself; but his eminent abilities were more fully displayed in the campaigns of 1672-77, in Holland, where he commanded a company in the duke of Monmouth's division of the allied army, and studied the art of war under Condé, Vauban, and Turenne. The latter, struck by his conduct at the siege of Niméguen, styled him his 'handsome Englishman,' and strongly recommended him to the notice of his superiors. At Maestricht he saved the life of the duke of Monmouth, and for his eminent gallantry received the public thanks of Louis XIV., as well as promotion to a lieutenant-colonelcy from his own sovereign.

He returned to England in 1677, after five years' experience in military affairs on the grandest scale, and under the most consummate leaders; an experience which, as Alison observes, undoubtedly fitted him for the brilliant part he was destined to play in the history of his time.

Early in 1678 he was married to Sarah Jennings, the confidential attendant of the Princess Anne, a woman of great beauty and considerable mental powers, whose influence over her husband remained unimpaired to the last. He was now attached to the service of the duke of York; was created Baron Churchill, of Eymouth, in Scotland; and, in 1683, appointed colonel of a newly raised regiment of dragoons. On the accession of James to the throne the fortunate soldier was loaded with additional favours; he was made an English peer, promoted to the rank of brigadier-general, and despatched to Paris to notify the accession of the new monarch.

When Monmouth commenced his abortive rebellion, Churchill was created major-general, and appointed second in command to the earl of Feversham. His skill and energy saved the royal army from a surprise on the eve of the battle of Sedgemoor, and largely contributed to the victory won upon that sanguinary field. For these services he received the colonelcy of the 3rd regiment of Horse Guards.

Churchill was therefore bound to James II. by the strongest ties of personal gratitude; but that monarch's designs against the Protestant religion and the freedom of England excited his disapprobation, and he secretly joined the powerful party which invited William of Orange to seize upon the English crown. But he did not do what, as an honest man, he should have done, retire from the service of the sovereign whose conduct he disapproved. While he carried on a clandestine correspondence with the Dutch prince, he accepted the command of a corps of 5000 men destined by James II. to oppose his progress, and accepted a lieutenant-generalship in the army which he intended to deliver up to his rival. And not only did he desert his generous master, but his influence and that of his wife secured the desertion

of that master's daughter; so that the heaviest blows inflicted upon James fell from the hand of the man whom he had loaded with the greatest favours. Such treachery can hardly be palliated by the fact, that in this respect Churchill was neither better nor worse than most of his contemporaries.

William III. duly rewarded Churchill for these important services. He received the earldom of Marlborough, and was named lieutenant-general of the army. Soon afterwards he was appointed to the command of the British auxiliary force in the Netherlands, and earned a warm eulogium from King William. 'I am very happy,' wrote the king, 'that my troops behaved so well in the affair of Walcourt. It is to you that this advantage is principally owing.'

He served in Ireland in 1699 with equal distinction. In thirty-seven days he reduced Cork and Kinsale, and confined the war to the province of Ulster. But from motives which it is unnecessary to elucidate—partly, perhaps, from his jealousy of the confidence which the king bestowed on his Dutch favourites; partly from a fear that some new revolution might recall James II. to the throne—he kept up a clandestine correspondence with the exiled monarch, and betrayed the secrets of his sovereign's councils. His treachery becoming known to William, he was deprived of all his commands, and thrown into the Tower. But so great was his influence that he soon obtained his release, and the king did not dare to bring him to trial. After living for some years in privacy he gradually recovered his place in the royal favour, was restored to his seat in the privy council, and named preceptor of the young duke of Gloucester, the son of the Princess Anne, and heir-presumptive to the throne. 'My lord,' said the king, 'make my nephew to resemble yourself, and he will be everything which I can desire.'

In 1701 broke out the War of Succession, which soon involved all Europe in the flames of battle. Marlborough was now summoned to a scene peculiarly adapted for the display of his consummate genius, and called upon to play a part in which the severest critic can but regard him with admiration. On the 1st of June, 1701, he was named ambassador-extraordinary to the Hague, and commander-in-chief of the allied forces in Flanders; an appointment which, as far as England was concerned, virtually invested him with the general direction of affairs, both civil and military, and strikingly showed the high estimate which William had formed of his ability as a diplomatist and his genius as a soldier. But while vigorously urging on preparations for the conduct of the war, William's career was suddenly terminated, and the Princess Anne succeeded to the throne. She immediately confirmed the appointments of her predecessor, and showered additional favours on her favourite and her favourite's husband. The earl received the Order of the Garter, and the countess was made Mistress of the Robes and Keeper of the Privy Purse. Thus distinguished by special marks of his sovereign's confidence, Marlborough repaired to the Continent, and entered upon that career of glory which has secured him a place among England's foremost worthies. In the English Valhalla few statues are placed higher than that of England's greatest general.

In judging Marlborough's military career, the reader

must remember that he was constantly hampered by the jealous interference and parsimony of the Dutch government, alive only to its own interests, and incapable of comprehending any grand scheme of European policy; and that he was frequently fettered by the intrigues of political parties at home. Over every obstacle, however, his genius triumphed, and to Marlborough alone is due the glory of having rescued Europe from French supremacy.

The campaign of 1703 was illustrated by numerous successes, and Varbor, Stevenswaert, Ruremond, and Liège fell before the allied armies. In the following year, by a succession of masterly movements, Marlborough, who had been elevated to a dukedom, diverted the war from the borders of Holland to the valley of the Danube, and prevented the combination, designed by Louis XIV., of three great French armies to overwhelm at one blow the inferior forces of the allies. After forcing the passage of the Danube beneath the guns of Schullenberg, a feat of the most brilliant daring, he encountered Marshal Tallard and the Elector of Bavaria near the village of Blindheim, or Blenheim, on the 13th of August, 1704, and inflicted upon them a crushing defeat. The allied forces, under Marlborough and Prince Eugene, numbered 56,000 men, with 52 guns; the French and Bavarians composed 60,000 men, with 90 guns. This disparity of numbers was increased by various circumstances. 'Four-fifths of the French army,' says Alison, 'were national troops, speaking the same language, animated by the same feelings, accustomed to the same discipline, and the most of whom had been accustomed to act together. The allies, on the other hand, were a motley assemblage, like Hannibal's at Cannæ, or Wellington's at Waterloo, composed of the troops of many different nations, speaking different languages, trained to different discipline, but recently assembled together, and under the orders of a stranger general. English, Prussians, Danes, Wurtembergers, Dutch, Hanoverians, and Hessians, were blended in such nearly equal proportions, that the army of no one state could be said by its numerical preponderance to be entitled to the precedence. But the consummate address, splendid talents, and conciliatory manners of Marlborough, as well as the brilliant valour which the English auxiliary force had displayed on many occasions, had won for them the lead, as they had formerly done when in no greater force among the Confederates, under Richard Cœur-de-Lion, in the Holy War.'

The immediate result of the victory of Blenheim was the capture of 13,000 prisoners, 34 guns, 25 standards, and 90 colours. The total loss of the enemy was not less than 40,000 men. The allied army had 4500 killed and 7500 wounded. The ultimate result was the destruction of that vast fabric of power which Louis XIV., aided by the talents of Turenne and Vauban, had laboured so long to construct.

Marlborough, on his return to England, was received with an enthusiastic welcome, and an Act of Parliament bestowed upon him the royal demesnes of Wootton and Woodstock, and decreed the erection of a splendid palace at the national expense. He opened the campaign of 1705 by the capture of Sluys, a success which he followed up by forcing the French entrenchments on the Meuse, though Villeroy had

exhausted all the resources of his skill upon their construction, and posted behind them an army of 70,000 men.

It is impossible in our narrow limits even to catalogue all the brilliant operations conducted by the genius of Marlborough. We must content ourselves with dwelling upon the more important. Thus, the campaign of 1706 was distinguished by the great victory of Ramilies (May 23), fought on a tract of elevated table-land which lies between the river Meuse and the Great Ghut. The two armies were nearly equal: the allies mustering 60,000, and the French, under Villeroy, 62,000. A brilliant charge, headed by Marlborough in person, decided the fortune of the day, and the French fled in complete disorder, with a loss of 6000 prisoners and 7000 killed and wounded. This victory delivered almost the whole of Austrian Flanders from the hard gripe of France. Brussels, Louvain, Mechlin, Alost, Sensi, Ghent, Bruges, Daun, Oudenarde, joyfully opened their gates to the victor. Only Dunkirk and Nieuport, Ostend and Antwerp, remained in the hands of the French, and these were reduced before the end of the campaign.

In 1707 Marlborough visited Charles XII. of Sweden, to secure his co-operation on the side of the allies. He was received by the northern warrior with the most marked distinction, and was completely successful in his mission.

The year 1708 was rendered famous by the victory of Oudenarde (July 11th), which crushed the army of Vendôme. The French numbered 85,000, and the allies 80,000 men. The action on both sides was fought with determined courage, but the genius of Marlborough and the persistent valour of his troops eventually prevailed. The French had 6000 killed and wounded, and 9000 made prisoners. 'If we had been so happy,' wrote Marlborough, 'as to have had two more hours of daylight, I believe we should have made an end of this war.'

Meanwhile, the strife of political parties in England had risen to a furious height, and the Tory faction did not hesitate to accuse Marlborough of prolonging the war for his own personal gain. Undeterred by their calumnies, the great general pursued his triumphant career, captured Lille, Ghent, and Brussels, and foiled the designs of the French marshal at every point. In the following year, on the 11th of August, he fought the sanguinary battle of Malplaquet, the last of his great victories, and in some respects the most extraordinary of his achievements. The French numbered 95,000 men, with 80 guns, under their two greatest generals, Villars and Boufflers. The allies counted 93,000 men, and 105 guns. But the position occupied by the French was one of extraordinary strength: they were posted on the summit of a steep acclivity, between two woods, and only accessible by two narrow and difficult defiles; and this acclivity bristled with redoubts and palisades, stockades and abatis, mounted with heavy guns, and defended by the finest troops of France. Yet against this apparently impregnable stronghold, which was really a masterpiece of engineering science, Marlborough dared to lead his soldiers. Charge upon charge was made with splendid impetuosity, and repulsed with steady valour. The fortune of the day seemed to waver in the balance, when Marlborough's

eagle eye detecting a weak point in the enemy's centre, hurled upon it a heavy force of infantry, supported by several columns of cavalry, and crushed through the hostile lines. The battle was won, but at such terrible cost that Marlborough could not pursue the retreating French, and its only substantial results, except that it proved, what the world already knew, the surpassing genius of the English commander, was the capture of Mons.

In this sanguinary fight the allies lost 5544 killed, and 12,706 wounded or missing; in all, 18,250. The total loss of the French was computed at 14,000, a difference due to the immense strength of their position.

On his return to England, Marlborough was received by the nation with indifference, by the queen with studied neglect. He found the reins of power slipping from his grasp, and his fall accelerated by the ungovernable temper of his wife, who had completely alienated the queen's affections. The Tory faction was daily increasing in favour at court and parliamentary influence, and the great general, disgusted with party intrigues, gladly returned to the Continent to resume the conduct of the war.

The campaigns of 1710 and 1711 were in themselves sufficient to have secured the renown of any other commander, but they could do little to increase the glory of the victor of Blenheim. His career, however, was cut short by the Treaty of Utrecht, somewhat hastily concluded under the auspices of a Tory ministry, and whose preliminaries were signed on the 27th of November, 1712. Marlborough immediately dismissed his army into winter quarters, and returned to England, where a storm of obloquy broke upon his devoted head. He was accused of fraud and peculation, and dismissed from all his appointments. The charges brought against him he rebutted with his usual serene composure, and then withdrew from the calumnies of an ungrateful people, to receive from foreign countries the honours which he so justly deserved. Wherever he passed, it is said, crowds of all ranks were waiting to see him, were it only to get a glimpse of the hero who had saved the empire, and filled the world with his renown. All were struck with his noble air and demeanour, softened, though not weakened, by the approach of age. They declared that his appearance was not less overpowering than his sword. His manner was so courteous and yet animated, his conversation so simple and yet cheerful, that it was commonly said at the time, 'that the only things he had forgotten were his own deeds, and the only things he remembered were the misfortunes of others.'

Marlborough warmly supported the Elector of Hanover's right of succession to the English throne. On the death of Queen Anne he returned to England (August, 1714), and received from George I. the appointments of Captain-general of the Army and Master of the Ordnance. His last professional service was to plan the details of the campaign of 1715-16 against the rebels in Scotland, but he did not in person take the field. The deaths of two of his daughters at short intervals were severe blows to his already weakened frame. On the 28th of May, 1716, he was seized with a severe paralytic fit, and the attack was repeated in November of the same year. He partially recovered from their effects, and

occasionally attended in his place in the House of Lords up to the 17th of November, 1721. In the following June he was prostrated by paralysis for the third time, and after lingering a few days, expired in peace, on the 16th of June, 1722.

(The reader may consult the following authorities in reference to the life and military career of this illustrious commander, who, we may add, was scarcely less able as a statesman and skilful as a diplomatist, while he was one of the greatest masters of the art of war the world has ever seen:—Coxe, *Life of Marlborough*; Lediard's *Life*; Alison's *Military Life*; Sir G. Murray's *Letters and Despatches*; Lord Macaulay, *History of England*; Dumont's *Military History*; Milner's *Journal of Marlborough's Campaigns*; Kausler, *Vie du Prince Eugène*; and Cunningham's *History of the Reign of Queen Anne*.)

MARLOW, GREAT. [BUCKINGHAMSHIRE.]

MARLOWE, CHRISTOPHER, was born, according to Malone, in 1565. He was entered of Corpus Christi College, Cambridge, took his bachelor of arts degree in 1583, and that of master of arts in 1587. On leaving the university he became a dramatic writer and perhaps an actor. His moral character appears to have been bad, and he was slain in a quarrel in a house of ill fame.

The following plays are attributed to him:—'Dr. Faustus,' 'Edward the Second,' 'The Jew of Malta,' 'Tamburlaine the Great,' 'Lust's Dominion,' 'The Massacre at Paris,' and 'Dido, Queen of Carthage.' The prevailing opinion, however, is that the first three only are his sole productions.

To Marlowe we are indebted for the first regular form of the English drama cleared of rhymes; and he may be considered as the link between the Moralities and Shakspeare. His style has been aptly characterized as 'Marlowe's mighty line,' and he frequently attains a high standard of poetical expression. 'Faustus' is nearly a 'morality,' 'Edward the Second' is a regularly formed 'history.' Besides his plays, Marlowe translated Ovid's 'Art of Love,' and some other classical works.

MARLSTONE, in Geology. Sandy, calcareous, and irony strata, which divide the upper from the lower lias clays, are thus designated. This mass of rocks is nowhere so well developed as in Yorkshire and Leicestershire. The term is also employed to designate species of coarse limestone of different ages.

MARMALADE, a sort of preserve made with sugar and the Seville or bitter orange, a variety of the fruit of the *Citrus Bigaradia*. It is more wholesome when properly made, i.e., when the rind is soft, than most other sweet preserves, as the bitter communicates tonic and stomachic properties to it.

MARMANDE. [LOT-ET-GARONNE.]

MARMARA, or MARMORA, SEA OF, the *Propontis* of the ancients, is situated between the Grecian Archipelago and the Black Sea, communicating with the former by the Dardanelles, the ancient Hellespont, and with the latter by the Strait of Constantinople, the ancient Bósporus. Its extreme length from W. to E., including the Gulf of Ismid, is 172 miles; and its greatest breadth is 55 miles. The sea is very deep. There are no tides, but a current sets in from the Bosphorus.

MARMONT, MARSHAL, DUKE OF RAGUSA (Augustus Frederic Louis Viesse de Marmont), one

of the most distinguished of Napoleon's generals, was born of a noble family at Chatillon-sur-Seine, on the 20th July, 1774. After receiving a good education he entered the army at the age of fifteen, as sub-lieutenant of infantry, but in 1792 he quitted the line for the artillery. At the siege of Toulon his skill and enthusiasm attracted Bonaparte's attention, and in 1796 he accompanied the young conqueror to Italy. At the battle of Lodi he carried away, at the head of a cavalry detachment, the first gun captured from the enemy; he also distinguished himself in the hot fight at Castiglione, and at the desperate battle of St. George largely contributed to the success of the day.

After the peace of Campo Formio in 1797, he returned to Paris and married the daughter of M. Perregaud, the wealthy banker. Matrimonial joys, however, could not turn him aside from the path of glory, and he followed Napoleon to Egypt, where he was intrusted with the defence of Alexandria. Constantly attached to Napoleon's person, he returned with him to Europe, and after the revolution of the 18th Brumaire was appointed a councillor of state, and promoted to the chief command of the artillery of reserve. At the great battle of Marengo he directed the artillery, and moved it within musket shot of the Austrian lines. At the end of this brilliant campaign he returned to Paris, and received as the reward of his services the inspector-generalship of artillery.

In the war of 1803 he effected the conquest of Styria, and being afterwards ordered to Dalmatia, he gained, with only six thousand troops worn with fatigue and disease, the victory of Castel-Nuovo, over 7000 Russians and 10,000 Montenegrins.

In the campaign of 1810 he was present at the decisive battle of Wagram, and for his gallant conduct at Znaim received a marshal's baton on the field. He was shortly afterwards created Duke of Ragusa, and appointed governor of the Illyrian provinces. From thence he was called, in 1811, to replace Marshal Massena in the command of the army of Portugal, which he found deplorably disorganized, but soon rehabilitated by his skill and firmness. Having effected a junction with the army of Soult, he forced Wellington, by superiority of numbers, to raise the siege of Badajoz, and then followed him up towards Salamanca. Here the two armies confronted each other in an attitude of expectancy, till a false movement of Marmont's placed him in the power of his wary antagonist, who inflicted upon him a crushing defeat. Marmont, severely wounded in the action, was obliged to have his arm amputated, and did not re-enter active service until the campaign of 1813.

After the fall of Napoleon, Marmont gave in his adhesion to Louis XVIII., and remained faithful to the Bourbons during the Hundred Days. In 1817, as the king's lieutenant, he suppressed a violent insurrection at Lyons, without bloodshed, by his sagacity and discretion.

When the Revolution of 1830 broke out, Marmont accompanied Charles X. to England, where he lived in retirement for several years. His name was expunged from the list of marshals by Louis Philippe, an act unworthy of the monarch, as the private character of Marmont was free from all reproach.

He died in 1852, in the seventy-eighth year of his age.

MARMONTEL, JEAN FRANÇOIS, was born at Bort in Limousin, in 1723. At an early age he became professor of philosophy at a seminary of the Bernardins at Toulouse, and supported his widowed mother and her family. An acquaintance with Voltaire brought him to Paris in 1745. Voltaire introduced him to several persons of distinction, and the success of his first tragedy, 'Denys le Tyran,' stamped him as a dramatic poet of no mean merit. His celebrated 'Contes Moraux' gained him great reputation. On the death of Duclos he became historiographer of France; and in 1783 secretary to the Académie in the place of D'Alembert. He lost his appointments and his property on the breaking out of the Revolution, and he removed some distance from Paris in a state of destitution. In 1796 he became a member of the National Institute, and in 1797 was elected into the council of the ancients, but this election having been reversed after the 18th Fructidor (September 4) in the same year, he retired to Abbeville, where he died in 1799, and was buried in his own garden by Catholic priests.

MARMORA, SEA OF. [MARMARA, SEA OF.]

MARMOSET (*Uapale*), a genus of *Platyrrhinae*, or American monkeys. They are small and elegant forms, and much sought after as pets. The marmosets are chiefly insect feeders, though they also take fruits and small birds. They inhabit the forests of Brazil. Above thirty species have been described. They are very nimble little creatures, and exceedingly graceful in their movements.

MARMOT. [MURIDE.]

MARNE, a department in France, formed out of a portion of the province of Champagne, is bounded N. by the departments of Aisne and Ardennes, E. by those of Meuse and Haute-Marne, S. by that of Aube, and W. by Seine-et-Marne and Aisne. Its greatest length from N.E. to S.W. is 81 miles, from N.W. to S.E. 74 miles. The area is 3154 square miles, and the population in 1861 was 385,498.

Surface, Soil, and Aspect.—From the centre to the north of the department the arid and almost barren soil consists of a thin layer of sandy earth not two inches in depth, and resting on a chalk bottom. These sandy plains, formerly destitute of all vegetation, have been lately planted with Scotch pines. Between Rheims and Fismes the land is good, and along the western border, and in the valley of the Marne, there is some strong deep land. Again in the Perthois district, in the south-east of the department, along a considerable margin from Vitry to Sainte-Ménéould, and in the valley of the Aisne, the soil is in general rich and productive.

Rivers.—The department takes its name from the river *Marne* (the *Matrona* of Julius Cæsar), which rises in the department of Haute-Marne, about 3 miles S. from Langres, and flowing nearly N. past St.-Dizier, then sweeps round to the west, and enters the department of Marne: here its course is N.W. past Vitry and as far as Châlons, whence it flows W., and continues in this general direction across the south of the department of Aisne, the north of Seine-et-Marne, and to its junction with the Seine at Charenton, in the department of Seine-et-Oise. Its whole length is 217 miles, of which 147, from

St.-Dizier to its mouth, are navigable. Its principal feeders on the right bank are the Rognon, the Saulx (which receives the Ornain), and the Ourcq; on the left bank the Blaise, the Collé, the Some-Soude, the Grand-Morin, and the Petit-Morin. The Marne is connected with the Rhine by a canal. The north of the department is drained by the AISNE.

Climate and Produce.—The climate is temperate and the air pure, except along the eastern and western borders of the department, where in the low, rich, and sometimes marshy bottoms fogs are not unfrequent at certain seasons of the year.

The vine for the production of the famous Champagne wines is the chief object of the landholder's care all through the department, more especially in the arrondissement of Rheims and Épernay, wherein the white wines of Sillery, Aï, Mareuil, Pierry, Épernay, and Dizy, and the pink wines of Verzenay, Verzy, Bouzy, Taissy, Cumières, Aï, Hautvilliers, Mareuil, Dizy, and Pierry (all of the first class, differing and distinguishable from one another by certain inexpressible elements of excellence), are produced from the hungry chalky soil on which little else than the vine bush will grow. The excellent qualities of the Champagne wines are owing, however, not wholly to the peculiarity of the soil, but in a great degree also to the unremitting care of the growers in the selection and management of their vines, and in the manipulation of the wines, which experience teaches them to make so as to suit the different palates of the lovers of Champagne in the various countries of the world. A curious fact is that the best white Champagne wines are made from black grapes. These are suffered to remain on the vine till they attain perfect maturity; when gathered they are put in the wine press, and the first pressings are set apart for wine of the first quality. The juice thus obtained is put into a tun, where it remains from twenty to thirty hours, after which time it is put into sulphured casks, and these are deposited in cool cellars. During the frosty weather the wine is transferred into other casks, and clarified by means of isinglass; this process is repeated once or twice (if necessary) after an interval of a fortnight each time. From the 20th to the 30th of March the bottling process for the effervescing wine begins, but this is sometimes delayed even to the end of May, as the greatest attention must be paid to the temperature of the air, otherwise the delicacy of the wine and its effervescence would be materially injured. The bottles are placed in deep cellars, so as to have the most equable temperature possible, in order to diminish the chance of loss by breakage, which, however, when the wines become brisk in the autumn, often amounts to 20 per cent. Some of the largest dealers have cellars excavated in the chalk-rock, with compartments and passages extending for several miles. They are furnished with tramways, ventilated and lighted with shafts, and usually contain thousands of pipes and millions of bottles in stock. One merchant, for example, has ordinarily about 5,000,000 bottles in stock, and his corks alone cost 6000*l.* a year.

A fine breed of sheep is reared in the department; game is abundant; deer and wild boars are met with in the forests; the rivers and ponds yield abundance of fish; poultry is plentiful; bees are carefully tended.

Chalk, flint, millstone of the best quality, building stone, potter's and brick clay, and turf, are the chief mineral productions.

The manufactures are woollen stuffs of all kinds, bonnets, and cotton hosiery, which centre chiefly at Rheims. There are also several tan-yards, dye-houses, paper-mills, glass-works, potteries, rope-walks, oil-mills, soaperies, and establishments for the making of Spanish white.

The most important article of commerce is Champagne wine, the great marts for which are Rheims and Épernay. Other articles of trade are corn, flour, and brandy.

Divisions and Chief Towns.—The department contains 2,019,015 acres, and is divided into five arrondissements, which with their subdivisions and population are as follows:—

Arronds.	Cantons.	Communes.	Pop. in 1861.
Châlons-sur-Marne, . .	5	105	58,007
Épernay, . .	9	177	95,740
Rheims, . .	10	181	147,025
Sainte-Ménéhould, . .	3	80	34,074
Vitry-le-François, . .	5	124	50,652
Total, . .	32	667	385,498

In the arrondissement of Châlons-sur-Marne, the chief town is CHALONS-SUR-MARNE, which is also the capital of the department. *Suippes*, a well-built little town, of 2204 inhabitants, stands E.N.E. of Châlons, on the Suippe, a feeder of the Aisne. *Vertus*, an ill built town at the foot of a high vine-clad hill, W. by S. from Châlons, has 2469 inhabitants, and a considerable trade in wine.

Of the arrondissement of Épernay, the chief town, *Épernay*, stands in a rich vine district, near the left bank of the river Marne, which is here crossed by a bridge of seven arches. The town is well built, clean, and well paved. It has a college, and 10,598 inhabitants, who manufacture hosiery, pottery, refined sugar, and leather; and trade largely in bottles, corks, wire, champagne wines, &c. *Dormans*, a small town W. of Épernay, on the left bank of the Marne, has 2244 inhabitants. *Fère-Champenoise*, S. of Épernay, the scene of the defeat of Marshals Marmont and Mortier by the Austro-Russian army under Schwartzberg (March 25, 1814), stands on the Pleurs, and has 2042 inhabitants. *Montmirail*, situated on a hill near the right bank of the Petit-Morin, a feeder of the Marne, has a population of 2610. Napoleon defeated a large force of Russians and Prussians here, February 11, 1814. *Sézanne*, an ancient and well built town, has 4450 inhabitants, who manufacture coarse woollens, hosiery, tiles, bricks, lime, pottery, flour, oil, and leather. Sézanne was formerly fortified, and stood several sieges; the site of its defences is now laid out in gardens and public walks.

In the arrondissement of Rheims, the chief town is RHEIMS. *Ay*, or *Aï*, near the right bank of the Marne and nearly opposite to Épernay, has 3418 inhabitants, who are chiefly employed in the culture of the

vine and in the distillation of brandy. *Fismes*, in the north-west of the department, on the left bank of the Vesle, is a well built walled town, with 2787 inhabitants, who manufacture woollen cloth, and trade in flour, wine, hemp, wool, &c.

Of the arrondissement of Sainte-Ménéhould, the chief town, *Sainte-Ménéhould*, situated in a pretty, well-wooded country on the Aisne, in the east of the department, has a college, and 4300 inhabitants, who manufacture hosiery, leather, and small wares. In the environs there are several iron forges, glass-works, and potteries. This place was destroyed by fire in 1719, after which it was regularly built. It was once fortified, and taken by Louis XIV. in 1653.

The arrondissement of Vitry-le-François is named after its chief town, *Vitry-le-François*, or *Vitry-sur-Marne*, a well-built, fortified town on the right bank of the Marne, 20 miles S.E. from Châlons, and has 7622 inhabitants. The streets are wide, straight, and clean; the houses are mostly of wood; the supply of water is from twenty-seven fountains, from which also streams run through all the streets. The central square, on one side of which is a church of large dimensions, is adorned with a handsome fountain, and planted with a double row of lime trees. The manufactures are hosiery, cotton yarn, oil; the chief trade is in corn, wool, wood, and charcoal.

The department, with the exception of the arrondissement of Rheims, which, with the department of Ardennes, is included in the see of the archbishop of Rheims, forms the see of the bishop of Châlons. It is comprised in the jurisdiction of the Cour Impériale and Academy of Paris, and belongs to the fourth Military Division, of which Châlons is head-quarters. It returns three members to the Chamber of Deputies.

(*Dictionnaire de la France; Annuaire pour l'An 1866; Statistique de la France.*)

MARNE, HAUTE, a department in France formed out of the southern part of the province of Champagne, and of small portions of Bourgogne, the duchy of Bar, and Franche-Comté, is bounded N. by the departments of Marne and Meuse, E. by that of Vosges, S. by Haute-Saône and Côte-d'Or, and W. by the department of Aube. Its greatest length is 78 miles, and the average width is 37 miles. The area is 2413 square miles, and the population in 1861 was 254,413.

The department is mountainous. The plateau of Langres, which links the Cevennes to the Vosges mountains, and forms part of the watershed between the Mediterranean and the Atlantic, covers the greater part of the south of the department, and sends northwards numerous ramifications along both banks of the Marne. These mountains rise near Langres to about 2500 feet above the sea; they diminish in height as they advance northwards. The valleys extend mostly north and south. In the arrondissement of Vassy, in the north of the department, there are some fine valleys and extensive plains. Here and there all through the department, outlying hills, either singly or in groups, give variety to the surface. More than one-third of the department is covered with forests, in which oak, beech, ash, maple, birch, and poplar are the principal trees.

Rivers.—The principal rivers are the MARNE, the MEUSE, and the AUPE.

Climate.—The climate is very healthy; the air is

pure and keen in the mountains, where the winters are very cold. In many of the valleys, especially in those that open into the basin of the Saône, the temperature is warm and equable.

Products.—The vine is extensively cultivated in favourable situations, and the wine made is of ordinary quality. The milch cattle of the department are of good breed; horses and sheep are small; goats are numerous; poultry and game of all kinds are plentiful.

The department has some of the most important iron mines in France; the metal is smelted and manufactured into bars, utensils, and tools in more than 100 furnaces and foundries, in which wood charcoal is the fuel exclusively used. Building stone, marble, alabaster, gypsum, &c., are quarried. Marl, brick-earth, fuller's clay, and turf are dug. Besides ironmongery and cutlery, the industrial products include brandy, vinegar, cotton and woollen yarn, drugget, woollen stockings, leather gloves, cast-iron tubes, paper, leather, beer, &c. Timber furnishes the principal article of export.

Divisions, Chief Towns, &c.—The department contains 1,544,571 acres, and is divided into three arrondissements, which, with their sub-divisions and population, are as follows:—

Arronds.	Cantons.	Communes.	Pop.in1861.
Chaumont, . .	10	195	83,386
Langres, . . .	10	210	97,414
Vassy, . . .	8	145	73,613
Total, . .	28	550	254,413

Of the arrondissement of Chaumont and of the whole department, the chief town is *Chaumont-en-Bassigny*, which stands on a hill at the junction of the Marne and Suize, in 48° 6' 47" N. lat., 5° 8' 19" E. long., 134 miles S.E. from Paris, and has a tribunal of commerce, a college, and 7140 inhabitants. The supply of water is from twelve wells and four fountains, to which last the waters of the Suize are raised by an hydraulic engine. The principal buildings are—the church of St. Jean, the college buildings, the hospital, the remains of the castle of the counts of Champagne, the public library, and the town-hall, an elegant modern structure. The manufactures are woollen stockings, gloves, serge, drugget, common woollen cloth, cotton and linen yarn, leather, beet-root sugar, &c. A good trade in iron and iron wares is also carried on. It was at this town that the allied powers concluded a treaty against Napoleon I. (contingent on his refusal to accept the terms proposed at Chatillon), on the 1st March, 1814. *Château-Villain*, 12 miles W. by S. from Chaumont, stands on the left bank of the Aujon, and has iron forges and smelting furnaces, and 1784 inhabitants. *Nogent-le-Roi*, 12 miles S. by E. from Chaumont, near the right bank of the Treire, is the centre of a considerable cutlery manufacture, and has 3443 inhabitants.

In the arrondissement of Langres, the chief town is LANGRES. *Bourbonne-les-Bains*, celebrated for its warm springs, is situated on the southern side of the plateau of Langres, and on the Apance, a feeder of the Saône. It is frequented chiefly by persons

troubled with paralysis and with gunshot wounds, and has a large military hospital. The regular season is from May to October; but the baths are frequented more or less during the whole year. The temperature of this saline spring is from 122° to 167° Fahr. Cotton, wool, and silk manufactures are carried on; there are also tanneries, foundries, and brick works. The inhabitants numbered 4080 at the last census. *Fayl-Billot*, S.E. of Langres, has 2335 inhabitants. *Montigny-le-Roi*, a small town of 1199 inhabitants, deserves notice on account of its situation near the source of the Meuse.

Of the arrondissement of Vassy, the chief town, *Vassy*, is prettily situated on the right bank of the Blaise, 28 miles N. from Chaumont, and has 2927 inhabitants, who manufacture calico, druggot, iron-mongery, pottery, and leather. There are several iron forges and smelting works near it. *Vassy* is noted in history for the massacre of its Protestant inhabitants, by order of the duke of Guise, in 1562. *Joinville*, situated on the Marne, at the foot of a hill, on the summit of which formerly stood the castle of the Sires de Joinville, has several iron works, a communal college, and 3390 inhabitants. The duke of Orléans, father of the late king of France, had the castle demolished in 1790; the church remained till 1792, when it was destroyed, with the tombs of the lords of Joinville, and all the curious relics it contained. In 1841 such of the remains as had been preserved or recovered were solemnly deposited in the cemetery of the town, and a tomb, with a suitable inscription, was erected over them at the expense of Louis Philippe. Machinery, woollen hosiery, druggot, tartan, linen, cotton, woollen yarn, and serge are manufactured in this town. *St.-Dizier*, a well built town, with wide regular streets, stands on the right bank of the Marne, which here begins to be navigable, at a distance of 9 miles N. from Vassy, and has a tribunal of commerce, a college, and 8077 inhabitants. The town-hall and the remains of an ancient castle are the most interesting structures in the town. Its chief industrial establishments are iron forges and foundries, docks for building vessels, and cotton factories. There is also a considerable export trade in iron, timber, &c. In 1544, *St.-Dizier* sustained a memorable siege by the Emperor Charles V., and in 1814 the French troops here twice defeated a portion of the allied army.

The department forms the see of the bishop of Langres, is included in the jurisdiction of the Cour Impériale and Academy of Dijon, and belongs to the seventh Military Division, of which Besançon is headquarters. It now returns two members to the Chamber of Deputies.

(*Dictionnaire de la France; Annuaire pour l'An 1866; Statistique de la France.*)

MARONITES, the name of a community of Christians belonging to the Western or Roman church, and living on Mount Lebanon. They are neighbours of, allied to, and in some places mixed with the Druses, and, like them, are partly independent of the Turkish power. [**DRUSES.**] The Maronites occupy the valleys and fastnesses of the principal ridge of Lebanon east of Beyrût and Tripoli, and they extend inland as far as the Bekaâ, or plain between the Libanus and Anti-Libanus. The town of Zhaklé, in the valley of Bekaâ, contains between

10,000 and 12,000 inhabitants, chiefly Maronites. But the tract of country in which the great bulk of the sect reside is called Kesranan. It extends along the Libanus ridge from the Nahr el Kelb, a stream which enters the sea 12 miles north of Beyrût, to the Nahr el Kebir, north of Tripoli, the ancient Aradus, on which side the Maronites border on the Nosairis, or Ansaryii, who extend to the northward towards Latakiah, and the Ismaelians, who live farther inland, near the banks of the Orontes. [**ISMAELITES.**] In their internal concerns the Maronites are governed by their own sheiks, of whom there is one in every village, from whose decision there is an appeal to the bishops, who have great authority; and in some cases to the emir of the Druses, and his divan, or council. The clergy are very numerous; the secular parish clergy are married, as in the Greek church; but the regular clergy, who are said to amount to 25,000, and are distributed among about 200 convents, follow the rule of St. Anthony, and are bound by vows of chastity and obedience. Every convent is a farm. The convents are under the jurisdiction of bishops, of whom there is one in every large village. They are under the obligation of celibacy, and collectively elect the patriarch, who is confirmed by the pope, whose residence is at the convent of Kanobin, in a valley of the Libanus, south-east of Tripoli.

The Maronites derive their name from a monk of the name of Maron, who, in the fifth century, collected a number of followers, and founded several convents in these mountains. When the Monothelite heresy prevailed in the East in the eighth century, many Christians who did not embrace its tenets took refuge in the fastnesses of Libanus, around the convents, and thus the name of Maronites was assumed by the population of the mountains. They were reconciled to the Church of Rome in the twelfth century.

The Maronite population is said to be above 200,000 individuals, and to contain between thirty and forty thousand men fit for military service. Their language is Arabic, and by their appearance and habits they belong to the Arabian race.

MAROONS (supposed to be derived from a Spanish-American word signifying *hog-hunters*), a name given in Jamaica to a peculiar race, sprung from runaway negroes, with some admixture of Spanish blood. After Jamaica was conquered from the Spaniards they occupied the mountainous districts, and in 1730 and 1795 rose in arms against the British power. They are now confined to a particular region, are noted for their hatred to the negro, and their great loyalty to the British crown. [**JAMAICA.**]

MAROT, CLÉMENT, born at Cahors in 1495, entered the service of the duchess of Alençon as page. He afterwards followed Francis I. to Italy, and was wounded and taken prisoner at the battle of Pavia. He experienced a succession of good and evil fortune, and remained attached to the French court. He is known for his 'Enfer,' a satire, his poetical version of 'the Psalms,' and his 'Roman de la Rose,' and various other works, which possess the simplicity of the age united with grace and poetical fancy. He died at Turin in 1544.

MARQUE, LETTERS OF. The system of reprisal for injuries to foreign potentates has been

legalized from the most ancient times, and the subjects of a state were armed with powers to make reprisals by the sovereign power, by an instrument called letters of marque. In pursuance of this principle it was in this country declared by the Statute 4 Henry V. c. 7, that if any subjects of the realm were oppressed in the time of truce by any foreigners, the king would grant *marque* in due form to all that felt themselves aggrieved. The sufferer first applied to the lord privy seal, who made out letters of request; and if after request of satisfaction was made the party did not make restitution to the person aggrieved, the lord chancellor then made out letters of *marque* under the great seal, and then the aggressor might be attacked. But this manner of granting letters of *marque* has long been disused, and they were only granted in time of war to merchants to fit out privateers for the purpose of preying on the commerce of any nation with whom we were at war. But this system even has been abandoned by this country.

MARQUESAS ISLANDS are situated in the Pacific, and extend about 200 miles in a N.W. and S.E. direction, between $10^{\circ} 30'$ and $7^{\circ} 50'$ S. lat., and 139° and 141° W. long. They were so called by their discoverers in honour of the marquis of Mendoza, the viceroy of Peru. A wide channel divides them into two groups, of which the south-eastern contains five, and the north-western eight islands. The former were discovered by Neyra in 1595; the latter, having been discovered by the Americans in 1797, are also called Washington's Islands.

The largest islands of the southern group are Santa Dominica, or Hiwaou, Santa Christina, or Tahuata, and Hood's Island, or Tiboia. The principal islands of the northern group are, Noukahiva, Nohiva, Uahuga, and Uapoa, or Roapoa. Noukahiva, the largest, is nearly 20 miles long from south-east to north-west, and 70 miles in circumference. Here the French have a small settlement, founded in 1842.

An elevated ridge of verdurous mountains traverses each island longitudinally, and in the larger one rises to an elevation of 2000 or 3000 feet. On both sides they throw out high offsets, which extend to the shores of the sea, and thus divide the littoral into valleys. The mountains are rugged, but the valleys fertile. The islands afford several excellent harbours, though the coast consists of a range of gloomy and precipitous cliffs. The climate is rather warm, but healthy. The inhabitants cultivate fruits and tropical plants. Land animals are few, but fish is abundant.

The population, estimated to number 13,000 altogether, belong to the same race that peopled the Society and Sandwich Islands, of which their language and bodily conformation offer undoubted proof. Their complexion is of a copper colour. They have carried the art of tattooing the body to a greater degree of perfection than any nation, those of distinguished persons being covered all over with regular figures of a very tasteful pattern. They are cannibals.

MARQUETRY and PARQUETRY are two names for grouping small pieces of wood into ornamental devices, the one for producing pictures and small decorative works, and the other for floors. Most *marquetry* work is a delicate kind of veneering. The ground-work is well-dried oak or fir, secured from

warping. The coloured woods are sawn into very thin plates, and dyed or otherwise prepared. They are then cut into the requisite shape by means of an exceedingly delicate saw, and the subsequent process is almost precisely similar to that of veneering and INLAYING. The cabinetmakers of France, Italy, Belgium, and Germany are remarkable for the beautiful *marquetry* furniture they manufacture. Sometimes the wood is inlaid with other materials, such as metal, ivory, shell, &c. *Parquetry* is a plainer kind of *marquetry*, little varied as to the different colours of the wood, and generally used as flooring. At Windsor Castle, the Royal Exchange, and other places, *parquetry* floors have been laid down in recent years.

MARQUIS, a title of honour in England, France and Italy. It ranks second in the five orders of English nobility. The younger sons of marquises are usually addressed as 'my lord.' [MARCHES.]

There were no English marquises before the reign of Richard II. In the reign of Edward III, a foreign marquis, the Marquis Juliers, was made an English peer with the title of Earl of Cambridge, and this circumstance probably suggested to King Richard the introduction of the new order of nobility. The person on whom it was conferred was his favourite Robert de Vere, earl of Oxford, created Duke of Ireland and Marquis of Dublin in 1385.

The only nobleman sitting in the House of Peers as a marquis, whose title dates before the reign of George III., is the marquis of Winchester. The other *marquisates* are all of recent creation, though most of them were old peerages under inferior titles.

The title seems not to have been known in Scotland till 1599, when the *marquisates* of Huntly and Hamilton were created.

MARRIAGE is an agreement by which a man and a woman enter into a mutual engagement, in the form prescribed by the law of the country in which they reside, to live together as husband and wife during the remainder of their lives.

Marriage is treated as a civil contract even by those Christians who regard it as a sacrament, and as typical of the union between Christ and the church. The religious character of the transaction does not arise until there has been a complete civil contract, binding according to the law of the country in which the marriage is contracted. The authority of the sovereign power in regulating and prohibiting marriages is therefore not affected by the superinduced religious character.

Among Protestants marriage has ceased to be regarded as a sacrament, yet in most Protestant countries the entrance into the marriage state is accompanied with religious observances. These are not, however, essential to a valid marriage, any further than the law may have annexed them to and incorporated them with the civil contract.

In England, marriage by mere consent of parties, until the passing of the Marriage Act in 1753, constituted a binding engagement; though if application were made to the ecclesiastical courts for letters of administration, &c., under a title derived through such irregular marriage, those courts sometimes showed their resentment of the irregularity by refusing their assistance, more especially where the non-compliance with the usual formalities could be traced

to disaffection to the Established Church. What the formalities required by the church before the Marriage Acts were, it is now immaterial to consider. Such of them as are not incorporated into any of the Marriage Acts are now of no use.

To constitute a valid marriage, as well before as since the Marriage Acts, it is necessary, 1st, that there should be two persons capable of standing in the relation of husband and wife to each other; 2ndly, that they should be willing to stand in that relation; and 3rdly, that they should have contracted with one another to stand in that relation.

1. The capacity of standing in the relation of husband and wife implies, that at the time of the contract there should be no natural or legal disability. Total and permanent disability on either side to consummate marriage will render the contract void. Temporary disability from disease does not affect the validity of a marriage. Temporary disability from defect of age does not invalidate the marriage, but it leaves the party or parties at liberty to avoid or to confirm such premature union on attaining the age of consent, which for males is fourteen, and for females twelve. A person who is already married is under a legal disability to contract a second marriage whilst the first wife or husband is alive.

Consanguinity within certain degrees, and affinity also, is a legal impediment to marriage. The degree of nearness which shall disable parties from uniting in marriage varies in different countries, and has varied at different periods in our own. [AFFINITY.]

The impediment to marriage arising out of consanguinity applies in the same degree to illegitimate as to legitimate consanguinity, and the impediment resulting from affinity is created by illicit connection as well as by marriage. The Council of Trent restricted the impediment of affinity arising out of illicit connection to the second degree.

2. Each party must have the will to contract marriage with the other. An idiot, therefore, who cannot understand the nature of the conjugal relation, is incapable of contracting marriage; and also a lunatic, except during a lucid interval. But, however absurd it may appear, children are presumed to have sufficient intelligence to understand the nature of the marriage engagement at seven; and though the contract is not absolutely binding upon them until they reach the age of consent, still the marriage of a child above the age of seven would prevent its forming a second marriage until the age of consent, as until that age it cannot dissent from the first marriage.

3. There must be an actual contract of marriage. This, at common law, might be by words of present contract, which would, without more, constitute a perfect marriage—or by words of future contract, followed by cohabitation.

The unlimited freedom of marriage was first limited in England by the Marriage Act of 1753 (26 Geo. II. c. 33), the principal provisions of which form the basis of the present law.

The restrictions upon the common law freedom of marriage are now embodied in two statutes.

The 4 Geo. IV. c. 76, contains numerous provisions:—Banns of matrimony are to be published in the church, or a public chapel in which banns are allowed to be published, of the parish or chapelry

wherein each of the parties dwells, immediately after the second lesson of morning service, or of evening service if there be no morning service, upon three Sundays preceding the solemnization (s. 2). No license of marriage (that is, dispensation from the obligation to publish banns) is to be granted to solemnize marriage in any church or chapel not belonging to the parish or chapelry within which the usual place of abode of one of the parties has been for fifteen days immediately before the granting of the licence (s. 10). A marriage must be performed between the hours of eight in the forenoon and twelve at noon. For the other provisions the Act should be consulted.

The 6 & 7 Will. IV. c. 85 (amended by 7 Will. IV. and 1 Vict. c. 22, and 3 & 4 Vict. c. 72), was passed chiefly in favour of those who scrupled at joining in the services of the Established Church; and it contains numerous provisions for this purpose.

Persons who object to marry in a registered place of worship may, after due notice and certificate issued, according to the provisions of this Act, contract and solemnize marriage at the office of the superintendent registrar, and in his presence and in that of some registrar of the district, and of two witnesses.

These statutes do not extend to marriages contracted out of England, or to marriages of the royal family, which are regulated by a particular statute, 12 Geo. III. c. 11.

In August, 1844, an Act was passed (7 & 8 Vict. c. 81) relating to marriages in Ireland, and for registering such marriages, which came into operation April 1st., 1845. It establishes a system very nearly similar to that which exists in England and Wales under 6 & 7 Will. IV. c. 85.

Generally speaking, a marriage, valid according to the law of the country in which it was contracted, is valid in every other country, but this depends upon the law of domicile of the parties: thus if the contracting parties being in the relation of husband and deceased wife's sister marry abroad where it is lawful, and they be of English domicile, then the marriage is a nullity in this country: but if the parties had been domiciled abroad, then the marriage would be lawful here also. This is the general rule of law among European nations and nations of European origin. All marriages must be registered.

In Scotch law, marriage is a consensual contract, requiring no particular solemnity, nor even written evidence, but only the consent of parties to complete it. The essential requisite of the contract is the present, deliberate, and unconditional consent of the parties contracting. When, therefore, either party is legally or physically disqualified to grant this consent, there can be no marriage. Legal disqualification may arise either (1) from the previous marriage of one or other of the parties, or (2) under the Act 1600, c. 20, from the divorce of either party on account of previous adultery between them; or (3) from their being within the forbidden degrees of relationship. Physical disqualification may proceed either from nonage, or from mental infirmity. Pupils under the age of fourteen in males, and 12 in females, are incapable of marriage; but minors after puberty may ratify by solemn consent a marriage contracted while in pupillarity. Unlike the English law, the consent of parents or curators is

not necessary to the marriage of minors in Scotland. Idiots, being incapable of consent, cannot contract marriage; so neither can madmen except in lucid intervals, nor persons while labouring under extreme intoxication. Incapacity to perform conjugal duties renders a marriage voidable at the instance of either party, but is not in itself a nullity pleadable by third parties. And when consent has been impeached through force, fear, fraud, or under essential error as to the identity of the person with whom the contract is entered into, the marriage is null.

Marriages are either *regular* or *irregular*. A regular marriage requires the publication of banns on three several Sundays before the ceremony, and must be performed by a regularly ordained clergyman in presence of at least two witnesses. Irregular marriages may be contracted (1) *per verba de praesenti*. An acknowledgment by parties of present marriage before witnesses will effectually constitute marriage; but a written declaration of marriage found in a person's repositories after death, or to be effectual only after death, will not have this effect.

(2) *By Promise subsequente Copulâ*.—A promise of marriage in writing, or admitted upon oath, on the strength of which intercourse has followed, if not in itself constituting marriage, is a good ground on which to bring a declarator of marriage. But the intercourse must be distinctly proved to be referable to the antecedent promise.

(3) *By Habit and Repute*.—Cohabitation at bed and board, along with the uniform, consistent, and general repute of the neighbourhood that the parties are husband and wife, is effectual to constitute marriage. But where the connection has begun in concubinage, a very clear proof of change of purpose will be required before such a marriage can be recognized by law.

Irregular or clandestine marriages are equally valid with regular marriages, provided one of the parties has resided in Scotland for twenty-one days preceding the date of marriage, or at the time usually resided there (19 & 20 Vict. c. 96). Their celebration, however, subjects all the parties present on the occasion to penalties, though these are seldom enforced. Formerly, all marriages not solemnized by a clergyman of the Kirk of Scotland were declared clandestine; but this has been altered by 4 & 5 Will. IV. c. 28.

Marriage, when once constituted, is irrevocable; and can be dissolved only by death or divorce. Divorce may proceed either on the ground of adultery, or of wilful desertion on the part of either spouse, persisted in for four years.

The effect of marriage on the property of the spouses is to convert the whole moveable estate of both into a *communio bonorum* or common stock. The heritable subjects belonging to either remain the property of the possessor; but the fruits, rents, and interest of those of the wife fall under and form portion of the common stock.

MARRIAGE, ROMAN. The right conception of the constitution and legal consequences of a Roman marriage is necessary to enable us to approximate to a proper understanding of the old Roman polity. Much of the obscurity that formerly attached to the subject has been cleared up by recent researches, and the essential alterations made by the Emperor Justi-

nian upon the law of the subject, have been clearly and distinctly ascertained.

By the Ante-Justinian law marriage was either *regular* (*matrimonium legitimum*) or *irregular* (*illegitimum*). The essentials of a regular marriage were right of intermarriage between the parties (*connubium*), the attainment of the ages of fourteen and twelve respectively, and the consent both of the parties themselves and of their fathers, if they still remained under their *patria potestas*. Of regular marriages there were two distinct kinds, according as the wife passed, or did not pass, into the hand (*in manum*) of her husband. A wife who passed *in manum* of her husband became at once a part of his familia. She was *tota uxor*, and *mater familiæ*. She was admitted to participate in the sacred rites of his house, and her personality was completely merged in that of her husband. In his family she held the place of his daughter, and was subject to his paternal authority equally with his children, in relation to whom she held the place of a sister. All her property passed to her husband as dowry (*dos*), and at his death she claimed a daughter's share of his inheritance. Her children were born, and remained in the power of their father, until they were liberated by emancipation or by his death. Among the Sabines marriage was always accompanied by this *conventio in manum*, and till the Etruscans were admitted to the state, a similar rule was observed at Rome. There were three modes by which a wife might pass into the hand of her husband—*Confarreatio*, *Coeemptio*, and *Usus*.

1. *Confarreatio* was a form of marriage confined to patricians, performed by the Pontifex Maximus and Flamen Dialis, and deriving its name from a corn cake employed on these occasions. It required the presence of ten witnesses, and could only be dissolved by *diffarreatio*. The offspring of such marriages were eligible for the highest sacred functions: and from them at first the various flamens and vestal virgins were exclusively selected. This form of marriage fell into disuse in the time of Gaius, and was abolished by Constantine in 394.

2. *Coeemptio* was an imaginary mutual sale (*mancipium*) in presence of five witnesses and the balance-holder.

3. A wife passed *in manum* of her husband *usu*, when she continued to live with him as his wife for a whole year uninterruptedly. If she wished to avoid the legal effects of this cohabitation, she might, according to the laws of the Twelve Tables, break the *usus* by absenting herself from her husband for three nights during the year. This form of marriage seems to have been introduced after the admission of the Etruscans to the state.

By a regular marriage *sine manu* the wife was only naturally, and not civilly, related to her children. Her property did not pass to her husband, and the patrimonial rights of the spouses were thus obliged to be defined and settled by marriage contracts. This was the form of marriage in the time of Gaius.

An irregular marriage was something more than mere concubinage. It was a valid marriage between those who had no *connubium*. There were, of course, no civil consequences, and no *patria potestas* resulting from it; and the consent of the parents of the parties was not required.

By the Justinianean legislation the complicated distinctions of the early Roman law were done away with. Marriage became a consensual contract, and a valid marriage (*justæ nuptiæ*) was constituted by the mere interchange of assent between parties, provided they were both Roman subjects, had reached the age of puberty, and, if minors, had obtained the consent of their parents.

MARROW, or MEDULLA, is the fat contained in the osseous tubes and cells of the bones. [BONE.] Spinal Marrow and Medulla Spinalis are names sometimes applied to the spinal chord.

MARRUBIUM VULGARE. [HOREHOUND.]

MARS, MAVORS, or MARSPITER (called *Mamers* in the Oscan language), the god of war among the Romans, generally considered as corresponding to the Greek *Ares*. He was worshipped in peace under the name of Quirinus (spear-bearer), and in war under that of Gradivus. As the protector of the country he was styled Mars Silvanus. According to a principle in Roman mythology, by which a male and a female deity are supposed to preside over the same object of fear or desire, the Romans had a goddess of war called BELLONA, but the name of the wife of Mars was Neria.

The first month (Martius) of the old Roman year, which consisted of ten months only, derived its name from this god.

Mars is generally represented with a beard, but in other respects like the Greek *Ares*. For the Greek god of war, see *ARES*.

MARS, the planet which comes next to the earth, in order of distance from the sun, is a brilliant star of a slightly red tint. On examination by a telescope, this colour is found to belong to parts of the surface of the planet which have been conjectured to be land; the rest, which appears somewhat green, being supposed to be sea. Certain white spots, which appear at each pole after the winter of its hemisphere, and disappear during its summer, have been ascertained to be snow. The apparent diameter of Mars varies from 3·6" to 18·28", being 6·29" when the planet is at its mean distance from the earth. The real diameter is ·517 of that of the earth, or 4113 miles. Its bulk is ·1386 of that of the earth, and its mass is ·0000003927 of that of the sun, or about the 2546000th part.

The planet revolves on its axis in 24^h 39^m 22·62, and the axis is inclined to the ecliptic 28° 51'. Its light and heat are 43 per cent. of those of the earth. The semi-axis major of its orbit is 1·5236923, that of the earth being assumed as the unit. Its distance from the sun is 142,000,000 miles.

MARSA'LA, a town at the western extremity of Sicily, which was built by the Saracens, contained, in 1862, 31,350 inhabitants, and belongs to the province of Trapani. The country around produces very good white wine, the annual yield being estimated at about 30,000 pipes, two-thirds of which are exported. This trade has entirely grown up within the present century, chiefly owing to Lord Nelson having adopted the wine for use in the British fleet in 1802. Marsala also exports corn, cattle, oil, salt, and soda, in small quantities. The city is inclosed by bastioned walls, and has a cathedral, several convents and abbeys, a gymnasium, cavalry barracks, a curious vibrating bell-tower, and a famous grotto and

well. There are salt mines and caves of white marble in the vicinity. Don John of Austria filled up the ancient port in 1580, to prevent its becoming useful to corsairs; and the new port, about a mile to the south, bounded by a mole, is adapted only for small vessels. Marsala occupies the site of Lilybæum, the ancient capital of the Carthaginian settlements in Sicily. It was chosen by Garibaldi as the landing-place of his volunteers in his famous Sicilian campaign in 1860. The port was once in possession of the Arabs, and was by them esteemed so highly that they called it 'Marsa Alla,' or 'Port of God.' Hence its present name.

MARSDEN, WILLIAM, a distinguished Oriental scholar, was born in Dublin, November 16, 1754. Early in life he entered the service of the East India Company, and was stationed at Bencoolen in Sumatra, where he remained about eight years, applying himself in the leisure afforded from his official duties to the acquisition of the native languages and knowledge of the country. He then returned to England, and in 1782 published his 'History of Sumatra.' In 1812 he published his 'Grammar and Dictionary of the Malay Language.' The two works we have mentioned have already been considered highly valuable contributions to our knowledge of the East, as is also his 'Essay on the Polynesian or East Insular Languages.' Mr. Marsden died of apoplexy in 1836. His valuable collection of coins and medals he gave prior to his death to the British Museum, and his library of books and Oriental MSS. to the newly founded King's College.

MARSEILLAISE HYMN. When Barbaroux summoned the youth of Marseilles—the 600 men 'who knew how to die!—to proceed with him to Paris during the great French Revolution, they introduced into the capital the revolutionary song which soon became so celebrated, commencing with the thrilling and fiery words, '*Aux armes! aux armes!*' and it has ever since been called the Marseillaise Hymn in their honour. It was, however, really written by Rouget de Lisle, an artillery officer, to commemorate the departure of a band of volunteers from Strasburg, both verse and music being composed in one night (1792). So magical was its effect, that it procured 400 additional volunteers in Strasburg in a single day, and soon became very popular throughout the whole army stationed in the north. Its use is now strictly forbidden throughout France.

MARSEILLES (the Roman *Massilia*), a seaport and city in France, capital of the department of Bouches-du-Rhône, is situated on the coast of the Mediterranean, 534½ miles by railway S.S.E. from Paris, in 43° 17' N. lat., 5° 22' E. long., and had 260,910 inhabitants in 1861. The mean temperature of the year at Marseilles is 57°; in winter, 45°; in summer, 72° Fahr. It is the chief port of the Mediterranean, and the steam-packet station for Italy, the Peninsula, and the East. The harbour is the most commercial in France, and capable of containing 1700 vessels; the entrance is so narrow as to admit only one ship at a time. Marseilles depends entirely upon its commerce, which is very extensive, and has rapidly increased since the conquest of Algeria by the French. This and other causes led, a few years since, to the construction of a large new port, called 'La Joliette,' and a third, 'Basin Napo-

leon,' was completed in 1864. These two ports are inclosed within an immense breakwater, 2200 metres (2406 yards) or nearly a mile and a half in length. The old natural harbour is now exclusively reserved for sailing vessels, the 'Joliette' being assigned to steamers. The number of vessels of all kinds which entered and cleared the port in 1865 was 18,000, of over 3,000,000 tons burthen. Marseilles gives title to a bishop, whose diocese comprehends the town and the arrondissement; it is also the head-quarters of the ninth Military Division.

The city of Marseilles is built round an inlet of the sea, which runs eastward into the heart of the town and forms the harbour. The old town occupies a triangular point north of the harbour. The port is defended by the cross-fire from the batteries of Fort St-Nicholas and the tower of St-Jean.

The streets of the old town are for the most part narrow, and the houses high, irregular, and massive. It contains numerous squares of vast magnitude: among others the Place-Neuve and Place-des-Grand-Carmes. The new town, which comprises two-thirds of the whole city, consists of wide handsome streets. Many elegant fountains add to their beauty, and give a relief to their monotonous regularity. The supply of water has, however, long been very deficient; and to remedy this a canal has recently been cut from the Durance. It is 60 miles in length, and is altogether a most stupendous work. Marseilles has a custom-house, an exchange, a very large lazaretto north of the town—one of the finest and best managed in the world; a mint, theatres, a tribunal of commerce, a national academy of sciences, letters, and arts; an academy of medicine, and many other learned societies; a national college, with a library of 61,000 volumes, a school of hydrography, a botanical garden, several museums, an observatory, an arsenal, and other public institutions; besides many literary, scientific, and charitable societies. The Catholic churches are thirty in number, including a new cathedral in the Italian style; there are also a Protestant church, and a synagogue; but the public buildings are of little architectural importance except the Hotel de Ville. The shops, however, rival in splendour the finest in Paris.

The chief imports are of raw cotton, wheat (chiefly from the Black Sea and the Sea of Azoff), coffee, oil seeds, silk, wool, olive oil, raw sugar, lead, iron, and coal, besides enormous quantities of ores and metals, timber, hides, spirits, dye woods, and divers articles from the Levant. Large quantities of silkworms' eggs have likewise been imported here of late from foreign parts, chiefly Japan, and great efforts are being made to revive the silk production in the south of France, but not much success has as yet been attained. The exports are wines, brandy, corn, refined sugar, dried fruits, oil, soap, hosiery, damask and other linens, woollens, silks, leather, &c. The local manufactures consist of soap, morocco and other leather, glass, porcelain, hats, gunpowder, alum, sulphur, vitriol, and cutlery. The refining of sugar and salt, calico printing, the distillation of brandy, essences, and liqueurs, cork-cutting, and the preparation of anchovies, dried fruits, olives and wine for exportation, are carried on. There are numerous flour mills, and other extensive manufactures of salt, soda, chloride of lime, cement, machinery, &c. Large quantities of

French coal are brought here, chiefly from the department of Gard. In the neighbourhood of the city are extensive lignite mines and stones quarries. An English company has just (1866) been formed for the purpose of making extensive improvements in Marseilles and its vicinity.

The town of Marseilles has undergone many changes. Founded by the Phœceans (600 B.C.) under the name Massilia, it fell into the hands of the Romans under Cæsar, but retained its original aristocratic constitution. It subsequently became the prey of Burgundians, Visigoths, and Franks. The Marseillais were active in the Crusades, and at the time carried on extensive commercial intercourse with the East. In the thirteenth century they organized themselves into a municipal republic; but they were soon after deprived of many of their privileges by Charles of Anjou. The Marseillais adhered to the house of Anjou, and their town was burned and sacked, in consequence, by the king of Arragon, in 1480. Upon the death of Charles, count of Maine, Marseilles came directly under the government of the French crown, to which it has ever since remained subject. It was ravaged by the plague in 1720.

MARSHAL (French, *maréchal*), a term which, in its origin, meant simply a groom or manager of horses, but from the importance of such an employment in a rude warlike nation, the office of marshal became invested with great military authority, which, according to the usage of the times, drew to itself a considerable civil jurisdiction, and even at present one of the principal officers of state in England is the king's marshal, which office is now held hereditarily by the duke of Norfolk, who is said to have the office of marshal of England, and also an honour in respect of which he is earl-marshal. In feudal times it was the duty of the royal constable and marshal to inspect the troops assembled before the king, and they also fixed the encampment of each noble. They likewise had the regulation of all matters connected with armorial bearings, standards, and ensigns. The constable's functions were abolished in the reign of Henry VIII., and the marshal then became the sole judge in questions of honour and arms, and he is still the president of the English College of Arms, and appoints the kings-at-arms, heralds, and pursuivants. In time of peace the office was executed in the aula regis, or king's great court. Upon the division of the aula regis the marshal appointed deputies in the new courts. In the King's Bench the marshal's deputy was called the marshal of the marshalsea of the king's court, or marshal of the King's Bench. In the Exchequer, the deputy was marshal of the Exchequer, or clerk of the marshalsea of the Exchequer. The duty of the acting marshal was regularly to attend the court, and to take all persons committed to his custody by the court.

Besides the earl-marshal, there is a knight-marshal, or marshal of the king's household. The dignity of marshal, under the title of marischal, formerly existed in Scotland and was hereditary in the Keith family, but in 1716 George, the tenth earl marischal, was attainted in consequence of his share in the rebellion, and the dignity has not since been restored. In France the highest military officers have been called marshals since the thirteenth century. [FIELD MARSHAL.]

MARSHALSEA. In the marshalsea of the king's household there are two courts of record:—1. The original court of the marshalsea is a court of record to hear and determine causes between the servants of the king's household and others within the verge, that is, within a circle of twelve miles round the king's palace, with a jurisdiction of pleas of trespass where either party is one of the king's servants. 2. The palace-court was erected by letters patent, 6 Charles I., confirmed by Charles II., and has authority to try all personal actions between party and party, though neither of them be of the king's household, provided they arise within twelve miles round Whitehall. The judges of this court are the steward of the king's household and knight-marshal; but the court is, in fact, held before a barrister deputed by the knight-marshal. The palace-court is held once a week in Scotland Yard, and causes are here brought to trial in four or five court-days, unless they are of sufficient magnitude or importance to induce either party to remove it into one of the superior courts. A writ of error lies from both courts into the court of King's Bench.

MARSHFIELD. [GLOUCESTERSHIRE.]

MARSH'S APPARATUS. [ARSENIC, DETECTION OF.]

MARSTON, JOHN, a dramatist in the reigns of Elizabeth and James I., the particulars of whose life, and even the dates of whose birth and death are, like those of many of his contemporary poets, very uncertain. Marston left several plays, of which the 'Malcontent,' printed in Dodsley's Collection, is the best; but from the title-page of the first edition (1660), it appears to have been written by Webster, and only altered by Marston. He also joined with Jonson and Chapman in 'Eastward Hoe.'

MARSUPIA'LIA, or MARSUPIATA (*Marsupium*, 'a purse' or 'bag'), an extensive group of Mammalia, differing essentially from all the others in their organization, and comprehending genera fed by every variety of nourishment. Their structure is, as a necessary consequence, modified accordingly; and we find among them an adaptation of the organs of progression, prehension, and digestion to their several wants and habits, so that we may trace in them analogies to the carnivorous, insectivorous, herbivorous, and rodent forms of the other mammiferous quadrupeds.

Cuvier, who had the advantage of knowing the great quantity of species and variety of forms discovered in New Holland, arranged the copious materials which that extraordinary country afforded in addition to the new American forms, as the fourth order of his *Mammifères*, dividing the now numerous group into several subdivisions, and placing the order between his *Carnassiers* and his *Rodentia*.

Professor Owen and many zoologists consider that the mammalia are divided into two sub-classes, viz. *Placentalia*, and *Implacentalia*. The *Implacentalia* are again divided into two orders or primary groups, *Marsupialia*, and *Monotremata*.

According to Professor Owen's arrangement five tribes come under the head of *Marsupialia*, namely, *Sarcophaga*, *Entomophaga*, *Carpophaga*, *Poephaga*, and *Rhizophaga*. These tribes are divided into several families, and these families into genera and sub-genera.

The order *Monotremata* comprises two genera, namely, *Echidna* and *Ornithorhynchus*.

Mr. Waterhouse, in his 'Natural History of the Mammalia,' appears to consider the *Marsupialia* as an order comprising two sections, *Monotremata*, and the true *Marsupialia*.

The *Marsupialia* or *Marsupialia*, says Mr. Waterhouse, 'are implacental mammalia, whose young are brought forth prematurely, and received in most instances into a peculiar pouch situated on the lower part of the abdomen in the female; both sexes are furnished with two bones called marsupial bones, which are attached to the anterior margin of the pelvis. The brain is deficient of both corpus callosum and septum lucidum; the cerebrum is small in proportion to the animal, and contracted in front, and its surface is smooth, and presents but few convolutions; the cerebellum is entirely exposed, and has the vermiform process large in proportion to the lateral lobes; the olfactory lobes are large. Two venæ cavae enter the heart.'

The quadrupeds which range themselves under the order *Marsupialia* are familiarly known as Opossums, Phalangiers, Kangaroos, &c. 'At the present period the great metropolis of the order is Australia. Certain species of the group, however, are found in the Molucca Islands, and one genus (*Didelphys*), containing many species, is peculiar to the New World, and although chiefly confined to the tropical portions, is met with as far north as the United States (where, however, one species only, *D. Virginiana*, is found), and extends in the southern direction to Buenos Ayres, on the east side of the Andes, and Valparaiso on the west. The species found in the islands north of Australia (if we except New Guinea), all belong to one genus, *Phalangista*, which occurs likewise in Australia, but they agree amongst each other in having the fur short, dense, and crisp, and the tail with the apical portion naked, and studded with fleshy warts—characters which, in the opinion of some naturalists, entitle them to the rank of a sub-genus, to which the name *Cuscus* is applied. No Phalangiers presenting these peculiarities have been found in Australia. In New Guinea the *Marsupialia* increase in numbers, since, notwithstanding its coast line is barely completed on our charts, and the interior is partially unknown, seven species of marsupial animals have been discovered in that island, and these appertain to six distinct genera, one of which only, it must be observed, is peculiar to New Guinea (viz. *Dendrolagus*). Of the species five are peculiar; one is said to be identical with a species found in New South Wales.'—Waterhouse.

The *Marsupialia* are divided by this eminent naturalist into the following families:—

1. *Macropodidae*. Locality, Australia and islands. Examples—The Great Kangaroo (*Macropus giganteus*); the Tree Kangaroos of New Guinea (*Dendrolagus*); the Rat Kangaroos, or Potoros of Australia and Van Diemen's Land. Examples—*Hypsiprymnus murinus*; *Macropus minor*, Shaw; Kangaroo Rat.

2. *Phascolomyidae*. Locality, Australia, Van Diemen's Land, and some of the islands of Bass' Straits. Example—The Wombat (*Phascolomys Wombat*).

3. *Phalangistidae*. Examples—The Koala (*Phascogale cinereus*). Locality, New South Wales.

The Vulpine Phalanger (*Phalangista vulpina*). Locality, Australia. The Spotted Phalanger (*Cuscus maculatus*). Locality, Amboyna, New Guinea, &c. The Flying-squirrel (*Petaurus sciureus*). Locality, New South Wales.

4. *Peramelidæ*. Example—The Long-nosed Perameles (*Perameles nasuta*). Locality, Norfolk Island and New South Wales.

5. *Dasyuridæ*. Examples—The Banded Myrmecobius (*Myrmecobius fasciatus*). Locality, Western

Great Kangaroo (*Macropus giganteus*.)

Australia. The Pencilled Phascogale (*Phascogale penicillata*). Locality, Australia. The Spotted Dasyurus (*Dasyurus viverrinus*). Locality, Australia. The Ursine Dasyurus (*Dasyurus ursinus*). The Dog-headed Thylacinus (*Thylacinus cynocephalus*). Locality, Van Diemen's Land.

6. *Didelphydæ*. Examples—The Virginian Opossum (*Didelphys Virginiana*). Locality, the southern portion of North America. The Water-Opossum (*Cheironectes variegatus*). Locality, Guiana, and Brazil.

At a former period, the marsupial animals were much more widely diffused than at present, as is proved by the discovery of their fossil remains, which occur not only in Australia and South America, but also in Europe.

'In the caverns which occur in the calcareous rocks in the interior highlands of Brazil, the bones of small opossums are very numerous; but these are for the most part very nearly allied to if not identical with species still living in Brazil. In Europe the most authentic remains of marsupial animals are those found in the gypsum quarries of Montmartre. The greater portion of a skeleton in which the marsupial bones remain in their natural position with regard to the pelvis, in which the lower jaw presents the angular portion curved inwards, and in which the molar teeth correspond precisely with those of *Didelphys*, leaves no doubt as to the existence of marsupial animals in Europe in the Eocene geological period. Besides this opossum-like animal, a lower jaw found in the same quarries has been referred to the marsupial group; it forms the genus *Pterodon* of De Blainville. In formations considerably lower in the series than the Eocene, in the Stonesfield oolite, have been found

VOL. VIII.

several rami of lower jaws of small insectivorous mammalia, some of which in their general form, and in the dentition which they present, approximate very closely to the insectivorous marsupialia. These, however, cannot be arranged in any known recent group of *Marsupialia*: they form the genera *Thylacotherium*, or *Phascolotherium*, of Professor Owen.

Virginian Opossum (*Didelphys Virginiana*).

To the latter genus belongs the *Didelphys Bucklandi* of Mr. Broderip, founded upon a very perfect ramus of the lower jaw, presented by that gentleman to the British Museum.

'The marsupial remains found in Australia are chiefly from the caverns of Wellington Valley, New South Wales. A considerable collection of these remains was found by the late Sir T. L. Mitchell, and are described in that gentleman's work, "Three Expeditions into the Interior of Eastern Australia," &c. It appears from the remains of these and other fossil remains from Australia, that they are referable for the most part to genera still presenting living species in the same country; there are some, however, which exhibit some very remarkable modifications of the marsupial structure, and form the types of new genera.'—Waterhouse.

Dr. Buckland observes, that 'the discovery of the *Marsupialia*, both in the secondary and tertiary formations, shows that this order, so far from being of more recent introduction than other orders of Mammalia, is in reality the first and most ancient condition under which animals of this class appeared upon our planet; that, as far as we know, it was their only form during the secondary period; that it was co-existent with many other orders in the early parts of the tertiary period; and that its geographical distribution in the present creation is limited to North and South America, and to New Holland, with the adjacent islands.'

MARTEL. [Lot.]

MARTEL, CHARLES. [CHARLES MARTEL.]

MARTELO TOWER, a circular building of masonry, generally two stories high. The lower story is divided into chambers for the reception of stores, and the upper serves as a casemate for troops. The roofs are vaulted, and that of the upper story is shell-proof. On the terreplein of the roof are placed pieces of artillery, which rest on platforms of timber traversing on pivots, so that the guns are capable of being fired in any direction. The whole work is generally surrounded by a ditch and glacis. They

F F

are generally built on the beach for coast defence, and occur in many parts of the United Kingdom, but especially opposite the French coast. They are generally considered to have been failures, and in nearly every case their armaments have been removed, and their garrisons replaced by coast-guardsmen.

Several Martello towers line the southern coast of England, having been erected during the war with France in 1804. They were suggested by, and derive their name from, a Corsican fort in Martella Bay, which had vigorously resisted a British expedition in 1794.

MARTEN. [WEASELS.]

MARTIAL LAW is a series of regulations made to preserve order and discipline in the army, and enforced by the prompt decisions of courts-martial: this is generally, however, called military law. During the existence of a rebellion, when, in consequence of the ordinary processes of law becoming ineffectual for the security of life and property in any province or state, the legislature has appointed that a military force shall be employed to suppress the disorders and secure the offenders; and when the trial of the latter takes place according to the practice of military courts, that province or state is said to be subject to martial law.

On the occurrence of such an event in any part of the British dominions, the two Houses of Parliament, jointly with the Crown, determine that a temporary suspension of the Habeas Corpus Act shall take place. This measure is adopted only in cases of great emergency; and the necessity of it and the time of its duration are always stated in the provisions of the Act. The Act by which martial law was declared in Ireland during the Rebellion in 1798, may be seen in Tytler's 'Essay on Military Law,' Appendix, No. 6. Martial law in this country is to be found in the articles of war made by the Crown under the authority of the annual statute called the Mutiny Act.

In merely local tumults the military commander is called upon to act with his troops only when the civil authorities have failed in preserving peace; and the responsibility of employing soldiers on such occasions falls entirely upon the magistrate.

The constitution of this country permits a military law for the government of the army, even in times of internal tranquillity, to co-exist with the general law of the land. But the former applies to military persons only; and at the same time any military person committing an offence against a subject of the realm, punishable by the law of the land, must be delivered over to the civil magistrate. The military jurisdiction comprehends all matters relating to the discipline of the army, to the cognizance of which the civil courts are not competent—as disobedience of orders, cowardice, &c.; and extends to such crimes as desertion, mutiny, and holding correspondence with the enemy.

MARTIALIS, MARCUS VALERIUS, was a native of Bībilis, in Spain, where he was born, about 40 A.D. He came to Rome at an early age, and passed about thirty-five years of his life in that city. About the commencement of Trajan's reign, he retired to his native town. Domitian gave him the 'jus trium liberorum,' and conferred on him the dignity of tribune ('Epig.' ii. 91; iii. 95), for which and

other favours the grateful poet made a most abundant return of flattery. Martial was acquainted with most of his literary contemporaries, Juvenal, Quintilian, Pliny the Younger, and others, as appears from his own writings (ii. 90; xii. 18, &c.)

There are extant of Martial fourteen books, entitled 'Epigrammata,' of which the thirteenth also bears the particular name of Xénia, and the fourteenth that of Apophoréta. A book called 'Liber de Spectaculis,' which is prefixed to the 'Epigrams,' contains a number of small poems on the shows of Titus and Domitian. The whole collection contains above 1500 epigrams.

As literary compositions Martial's Epigrams deserve high praise, and he has been justly styled the Virgil of epigrammatists. Their subjects are very various; praise of rural life, sarcastic invective against folly and vice, and elegiac pieces in honour of the dead, alike employ his muse, and are illustrated by his genius. In an historical point of view his works are very valuable, and they present a vivid picture of the atheism, luxury, prodigality, profusion, avarice, and cruelty which in his time made Rome hideous. Some of his epigrams, it should be added, do not answer to the modern idea of that class of composition, but are really short and sometimes pathetic sonnets on different themes, free from obscurity of expression or satirical point.

The best editions of Martial are those of Lemaire, 1825; and Schneidewinn, 1842.

MARTIGUES. [BOUCHES-DU-RHÔNE.]

MARTIN, the name for some of the Swallow tribe, as the *House Martin* (*Hirundo urtica*, Linn.), the *Bank* or *Sand Martin* (*Hirundo riparia*), and the *Black Martin*, or *Swift*. [SWALLOWS.]

MARTIN I. II. III. IV. V. [POPE.]

MARTIN, JOHN, an eminent English painter, was born near Hexham, in Northumberland, in the year 1789. Like most great artists, he evinced a remarkable artistic talent at a very early age, and from the first declared his determination to follow no other profession. He commenced, however, at the lowest step of the ladder, and with a view to becoming an heraldic painter was apprenticed to a Newcastle coachmaker, with whom he remained about a twelvemonth. His skill as a colourist had already been manifested, and his parents now placed him under the care of an Italian artist named Boniface Musso. In 1806 he removed to London, to reside with his master's son, the well-known enamel painter, Charles Musso or Muss.

When in his nineteenth year he married, and for some time supported his wife and himself by teaching a few pupils, and painting designs on glass and china. His difficulties were almost insuperable. While engaged on his first great picture, 'Zadak in search of the Waters of Oblivion,' he was frequently brought to the verge of starvation. It is related of him that, on one occasion he found himself reduced to his last shilling—a bright shilling, which he had preserved on account of its very brightness, but at length was constrained to exchange for bread. He went to a baker's shop, bought a loaf, and was taking it away, when the tradesman snatched it from him and flung back the shilling, because it was a *bad* one. Returning to his lodgings he searched for some forgotten crust to satisfy his hunger. Supported by the inspir-

ing energy of a self-reliant mind he struggled on; he had the courage to work and wait, and at length the picture was ready for exhibition. 'But you may guess my anxiety,' says Martin himself, 'when I overheard the men who were engaged to put it in the frame, disputing as to which was the top of the painting!' It soon, however, attracted the attention of connoisseurs, and Martin found himself famous.

His 'Clytie,' a beautiful work, was exhibited at the Royal Academy in 1814. Then followed the grand design of 'Joshua commanding the Sun to stand still,' and 'Belshazzar's Feast,' which, exhibited in 1821, gained the prize of 200*l.* at the British Institution.

Martin's most celebrated pictures are 'Macbeth,' the 'Fall of Babylon,' 'Destruction of Herculaneum,' the 'Creation,' the 'Deluge,' the 'Seventh Plague,' the 'Paphian Bower,' and the 'Fall of Nineveh,' all displaying the same conspicuous qualities—a lofty imagination, a fertile fancy, and a curious exaggeration of colour. There is thought, fancy, talent, in all his pictures, but his conceptions are frequently extravagant, and in carrying them out he too often oversteps 'the modesty of nature.' Some of his finest ideas will be found in his illustrations to Milton, with whose sublime and unworlly imagination he was well-fitted to sympathize. He left unfinished three large works, the 'Judgment,' the 'Plains of Heaven,' and the 'Day of Wrath.' Having retired to the Isle of Man, he was suddenly seized, while painting, with paralysis, on the 12th of November, 1853. Losing the power of speech and the use of his right hand, no expectation of his recovery could reasonably be entertained, and after a lingering illness, he expired in February, 1854, aged sixty-five.

MARTIN, SAINT. [ANTILLES.]

MARTIN-DE-LA-RÉ. [CHARENTE INFÉRIEURE.]

MARTINI, GIAMBATTISTA, was born at Bologna in 1706, and died in 1784. He became maestro di capello in 1723 in the Franciscan convent, to which order he belonged. His sixty Canons in the unison, for two, three, and four voices, are still known and admired; but his chief reputation rests on his 'Essay on Counterpoint,' published in two folio volumes at Bologna, in 1774, and on his 'History of Music,' in three volumes 4to, the last of which appeared in 1781.

MARTINIQUE, or MARTINICO, one of the French West India islands, between lat. 14° 24' and 14° 53' N., long. 60° 50' and 61° 18' W., with an area of 381 square miles, and a population (in 1861) of 136,562, of whom 87,000 are black. In form it is very irregular, and its surface is very uneven, being generally occupied by conical-shaped hills, of which one, Mont Pelée, is an exhausted volcano. The island contains a great number of streams, which are used to turn sugar mills, and the coast, being indented by numerous bays and inlets, affords many good harbours. About one-fourth of the surface is covered with dense forests. The climate is moist, but healthy; and the soil fertile. The two principal towns are Fort de France (formerly Port Royal), the capital, and St. Pierre, which is the most populous town. The former is on the north coast, and has 13,101 inhabitants. It is the residence of the governor, has a tribunal and chamber of

commerce, and a college and garden for the naturalization of East Indian plants. The harbour is excellent, and is defended by two forts. Fine liqueurs and preserves are exported. *St. Pierre* is an open roadstead on the western coast, affording very indifferent shelter to shipping, but it is the principal place of trade in the island, and it is said to be the handsomest town in the West Indies. It has 23,000 inhabitants, numerous public buildings and schools, a theatre, and a botanical garden. The roadstead is defended by several forts. The Empress Josephine, the first wife of Napoleon I., was born here in 1763.

The staple production of the island is sugar, to which is added small quantities of coffee, cotton, cocoa, and cloves.

Martinique was first settled by a party of about 100 men, headed by a French planter, M. Desnambre, from St. Christopher, in 1635. It was taken in 1762 by the English, but was restored at the peace in the following year. In 1794 it was again taken by the English, and again restored to France at the peace of Amiens. It was once more captured by the English in 1810, and finally restored by the treaty of Paris in 1814, since which time it has remained under the dominion of France. At the beginning of 1839 it suffered greatly from an earthquake. Slavery was abolished by decree of the French Republic in 1848.

MARTYN, HENRY, known as *The Missionary*, was born at Truro, 1781. He went to Cambridge in 1797, and became senior wrangler in 1801, and a fellow of St. John's in 1802. His intimacy with the Rev. Charles Simeon led to his adoption of ardent religious principles, and ultimately to his devoting himself to the duties of a missionary in 1805. In this capacity he traversed large tracts of India and Persia, and finally died at Tokat, in Asia Minor, in 1812.

MARTYR, JUSTIN. [JUSTIN MARTYR.]

MARTYRS, MARTYROLOGY, from the Greek *Martur*, 'a witness.'

By the term *martyr* we now generally understand a person who suffers death rather than renounce his religious opinions; and those who have made a profession of their faith and thereby endured sufferings short of death are called *confessors*. The annals of the early Christian church contain the histories of many martyrs, whose astonishing fortitude under the most cruel tortures was doubtless one great cause of the rapid diffusion of Christianity. We learn from the writings of Cyprian, bishop of Carthage in 248, that the sufferings of martyrdom were held to purge away the stain of sin, so that the martyr was admitted at once into paradise without needing the fires of purgatory. Martyrs were thought to expiate by their blood not only their own sins, but those of other men, and even of the church; and the fiery baptism of martyrdom was accounted of equal efficacy with the sacraments of Christ. The earliest account of a Christian martyrdom is that of Stephen in the Acts (vii.). It is very difficult to ascertain the number of martyrs who suffered in the early persecutions.

The opponents of Christianity have at times endeavoured to show that its martyrs were inspired by political rather than by religious motives. It is possible that some among them may have embraced

Christianity as a means of opposition to a tyrannical ruler, though no proof of such an opinion has been adduced on any credible authority; but all sensible persons will refuse to believe that party spirit or political enthusiasm could contribute many names to the roll of martyrdom. Truth, and the secret influence of God on the heart of man, can alone arouse that sublime devotedness which no tortures can daunt, and which confronts death with heroic calmness.

That department of ecclesiastical history which relates to the acts and deaths of martyrs is termed *Martyrology*; and a work embracing one or more such narratives is called a *Martyrology*.

MARVEJOLS. [LOZÈRE.]

MARVELL, ANDREW, a celebrated English patriot, and an acute, learned, and witty satirist, was born in 1620. His father—a learned and pious clergyman—was master of the grammar-school, and lecturer of Trinity Church, Hull. At fifteen Marvell was sent to Trinity College, Cambridge, and made rapid progress in his studies. Shortly after the death of his father in 1640, he quitted college and went to the Continent, where he spent four years in Holland, France, Italy, and Spain. After his return to his native country, probably about 1642 or 1643, he was employed in giving instructions in the languages to a daughter of Lord Fairfax. In 1657 he was associated with Milton in the office of Latin secretary to the Protector, with a salary to each of 200*l.* per annum. He was chosen by the citizens of his native town to represent them in the Convention, or 'healing' Parliament of 1660; but how far he approved of its proceedings in restoring Charles II., without any security against arbitrary and unconstitutional policy, cannot now be ascertained. We learn, however, that at this time he generously interposed on behalf of Milton, who had been committed to the custody of the sergeant-at-arms; and when 'Paradise Lost' was published, he had the courage to greet the immortal epic with a copy of eulogistic verses. Marvell continued to represent Hull as long as he lived. He wrote daily to his constituents during the sitting of Parliament, and frequently at other times communicated full information respecting public affairs. For some unknown reason, he appears to have been absent from his post between June, 1661, and March, 1663; and in June of the latter year he accompanied Lord Carlisle on an embassy to Russia, Sweden, and Denmark. His absence spared him the pain of witnessing the arbitrary and ruinous measures by which the Parliament and the country were at this period disgraced, and which he could not have opposed with any hope of success. He returned to his parliamentary duties in 1665, when the Parliament was sitting at Oxford, on account of the plague then raging in London. At the commencement of his parliamentary career, Marvell was far from being unfriendly to the Court; but the arbitrary proceedings and licentious lives of Charles and his ministers completely alienated the honest and public-spirited senator, and during the remainder of his career he acted with a small band of patriots, who cautiously, but firmly, resisted the unconstitutional policy of the government. No means were omitted to win over so powerful an opponent; but Marvell's integrity was proof alike against danger and against corruption. He equally despised threats

and bribes. In 1672 Marvell was involved in a controversy with Dr. Samuel Parker, afterwards bishop of Oxford, who had published a book called 'Ecclesiastical Polity,' in which he inculcated the slavish doctrine of divine right and passive obedience. Marvell's reply, 'The Rehearsal Transposed,' displays a mixture of brilliant wit, pungent sarcasm and irony, and sterling argument, which was received with avidity by all classes of people, and which Swift said he perused with pleasure. The 'Second part of the Rehearsal Transposed' appeared in 1673. In 1676 he published another controversial piece entitled 'Mr. Smirke, or the Divine in Mode,' &c., in defence of Dr. Croft, bishop of Hereford, who had been violently assailed by the high church clergy for his liberality and toleration. His next publication, which appeared in the early part of 1678, was entitled 'An Account of the Growth of Popery and Arbitrary Government in England,' and so provoked the government by its truth and biting satire, that a reward was offered for the discovery of the author, printer, or publisher of what was termed 'seditious and scandalous libel.' No prosecution, however, took place. Marvell died shortly after, 16th August, 1678. The corporation of Hull voted a sum for his funeral expenses and for an appropriate monument. Marvell was the last member of Parliament who received wages from his constituents.

MARY I., Queen of England, was the daughter of Henry VIII., by Catherine of Arragon, and was born at Greenwich on the 18th or 19th of February, 1516. She was brought up from her infancy in a strong attachment to the ancient religion, but was induced, from motives of self-interest, to comply with the reforms of her father. Her adherence to the Roman faith finally induced Edward to attempt to exclude her from the succession. [GREY, LADY JANE.]

Mary was scarcely seated on the throne when she proceeded to re-establish the ancient religion. The indications given by the court of a determination to be completely reconciled with Rome were followed by an insurrection headed by Sir Thomas Wyatt, January, 1554, which was in a few days effectually put down. Its suppression was followed by the executions of Lady Jane Grey, her husband, and father, and finally of Wyatt himself.

On July 25, Mary was married to the prince of Spain, afterwards Philip II.; and the reunion with Rome was completed by a parliament which assembled in the beginning of November, and which passed acts re-establishing the whole national system of religious policy as it had existed previous to the first innovations made by Henry VIII. The remainder of the history of the reign of Mary is occupied chiefly with the sanguinary persecutions of the adherents to the reformed doctrines. On the most moderate calculation, and making every reasonable allowance, it will be found 'that in the space of four years almost two hundred persons perished in the flames for religious opinion.' The principal political result of the Spanish alliance was the loss of the town of Calais, the last of the English possessions in France. Mary died, November 17, 1558. She left no issue, and was succeeded by her half-sister Elizabeth. [ELIZABETH.]

MARY STUART, Queen of Scotland, was born December 7, 1542. She was the third and only sur-

living child of James V. of Scotland, by Mary of Lorraine, daughter of the duke of Guise. At the time of her birth her father lay sick in the palace of Falkland; and a few days afterwards he expired. The ambitious Beatoun, archbishop of St. Andrews, produced a testament which he pretended was that of the late king, and immediately assumed the office and title of regent. The instrument was discovered to be a fraud; but Beatoun did not lose his influence, and on September 9, 1543, Mary was crowned by the archbishop, who was appointed lord high chancellor of the kingdom. He had even the address to win over the regent Arran to his views, both political and religious; and thus the French or Roman Catholic party obtained the ascendancy, in furtherance of the objects of which Mary was married to Francis, the dauphin of France, April 24, 1558, and her early years were passed amidst the gaieties of the French court. On the death of Queen Mary of England, claims were put forth on behalf of the Queen of Scots through her grandmother, who was eldest daughter of King Henry VII.; and notwithstanding Elizabeth had ascended the throne, those claims were urged with great pertinacity by the princes of Lorraine, her uncles.

Henri II. died in July, 1559, and in September of the same year Francis was solemnly crowned at Rheims. Mary was now at the height of her splendour; it was doomed, however, to be of short continuance. In June, 1560, her mother died; and in December of the same year, her husband. She then returned to Scotland, and landed at Leith, August 19, 1561, after an absence of nearly thirteen years. During that time Presbyterianism had gained the ascendancy in Scotland, and Mary's adherence to the old faith would have put an end to her popularity, but for her amiability and graceful manners. On the 29th of July, 1565, she was married to her cousin Henry Stuart, Lord Darnley, the youthful heir of the house of Lennox. It has recently been discovered, however, that a secret marriage had taken place four months previously. This marriage was not a popular one in several quarters, and though it gave no general dissatisfaction, there existed no real sympathy between the queen and her people. Her patronage of favourites was generally condemned. Of these the principal were Chastelar the French poet, and the Italian musician, Rizzio. Of these, the former was executed, and the latter murdered by some of the Protestant leaders in complicity with Darnley, whose jealousy had been aroused. Darnley, himself, died not long afterwards under suspicious circumstances. After a short stay in Glasgow, he had returned to Edinburgh with the queen, when he was lodged, not in the palace of Holyrood, as heretofore, but in the house of the Kirk of Field, a mansion standing by itself in an open and solitary part of the town. Ten days after, the house was blown up by gunpowder, and Darnley and his servants buried in the ruins. Whether Mary knew of the intended murder is not proved, but she certainly did not disapprove of it after it was accomplished. The author of the horrid deed was the earl of Bothwell, who was brought before the privy council for the crime; but in consequence of the shortness of the notice, Lennox, his accuser, did not appear, and without a single witness being examined, he was acquitted. Three

months after, having in the interval met the queen, and carried her off a prisoner to his castle of Dunbar, and obtained a divorce against his wife on the ground of consanguinity, he was married to Mary, who had previously created him Duke of Orkney (May 15, 1567).

Public indignation could no longer be restrained. The nobles rose against Bothwell and Mary, who fled before an armed and indignant people from fortress to fortress. At length, after they had collected their followers, a pitched battle near Carberry Hill was about to ensue (June 15, 1567), when Mary abandoned Bothwell, and threw herself on the mercy of her subjects. They conducted her first to Edinburgh, and thence to the castle of Lochleven, where it was determined she should at once abdicate in favour of the prince her son, James. Instruments of abdication to that effect were accordingly prepared, and she was at last constrained to affix her signature to them; upon which the prince was crowned at Stirling, July 29, when little more than a year old. Mary continued a prisoner at Lochleven, but in a few months effected her escape, and collected a considerable army. The battle of Langside ensued, and she was completely routed; whereupon she fled into England, hoping to secure the favour of Elizabeth. In this, however, she was mistaken. Elizabeth detained her a captive till the end of the year 1586—a period of about nineteen years, occupied in various plots for dethroning her great rival—when she was accused and declared guilty of being accessory to Babington's conspiracy, and beheaded at Fotheringhay Castle, February 8, 1587.

MARY II., wife of William III. [WILLIAM III.]

MARY, DUCHESS OF WÜRTEMBERG, or the Princess Marie d'Orleans, was born in April, 1813, during the exile of her father Louis-Philippe, then duke of Orleans, and residing at Palermo with his wife Amelia. She was married to the duke of Würtemberg in 1837, and died at Pisa in January, 1839, in consequence of injuries suffered from the conflagration of her palace at Stuttgart.

From her childhood she evinced a great love for art, and her father procured for her some excellent instructors. Some of her works in sculpture have acquired a European reputation; among these her marble statue of Joan of Arc is the most popular. She executed also an equestrian statue of the heroine, and a small model of the Death of Chevalier Bayard.

MARYBOROUGH. [QUEEN'S COUNTY.]

MARYLAND, one of the United States of North America, lies between 38° 3' and 39° 44' N. lat., and 75° 10' and 79° 20' W. long. It is divided into two portions by Chesapeake Bay and the Susquehanna. That portion which is east of the bay is bounded S. by Virginia and E. by the Atlantic Ocean and Delaware. Pennsylvania forms the whole northern boundary of this state, and Virginia and the Potomac form the boundary of the rest of the state. The area is 9356 square miles, and the population in 1860 was 687,049, of whom 83,942 were free coloured, and 87,189 were slaves.

Surface and Soil.—On the eastern shore, and in some counties on the western, the soil is a mixture of clay and sand, not very fertile, but easily improved by manure, which is found in extensive beds of marl abounding in the district. The country near the sea is level, but on the west there are some hills.

The line of the Atlantic coast is only 33 miles, but including Chesapeake Bay, is 411 miles.

Rivers.—The Potomac rises within the Appalachian mountains, with two branches: the northern branch rises in 39° 12' N. lat., on the eastern declivity of the Backbone range. Twenty miles below Cumberland it is joined by the southern branch, which rises in the centre of Virginia, about 38° 25' N. lat. After this junction the Potomac flows S.E. and S. till it falls by a wide estuary into Chesapeake Bay. The Potomac is navigable to the city of Washington, and is 10 miles wide at the mouth, and one mile at Alexandria, to which place it is navigable for vessels of the largest class. [ALEXANDRIA.] The Patuxent is 90 miles long, and is navigable for 50 miles by vessels of 250 tons burthen. The Patapsco is a small river navigable to Baltimore. The Susquehanna traverses the northern part of Maryland for 15 miles, before it falls into Chesapeake Bay.

Climate and Productions.—The climate is rather mild in the level part of the country, but the winter is sometimes severe enough to block up the harbour of Baltimore with ice for some weeks. Rain is rather abundant; drought is rare.

Wheat, Indian corn, barley, oats, tobacco, honey, silk, wool, maple sugar, and timber of many kinds, are the chief products. The common fruits of England, as apples, pears, plums, and peaches, succeed in most places. The whole country was originally covered with a dense forest, of which part still remains. Along the coasts of the Atlantic and the adjacent swamps a wild vine grows, whose fruit yields a pleasant wine.

In the forests on the mountains, wolves, bears, and deer are still found.

The minerals of this state comprise rich veins of copper and iron ore; coal, lead, cobalt, alum, lime, manganese, gold, &c.

Railways, &c.—Upwards of 500 miles of railway are in operation in Maryland, besides the Chesapeake and Delaware, and the Susquehanna canals. The state is also the seat of several manufactures, and is the sixth in commercial importance in the Union. It has several universities, colleges, and public schools.

Political Divisions and Towns.—Maryland is divided into twenty-one counties. The following are the principal towns, with the population of each in 1860:—*Annapolis* is the capital of the state. [ANNAPOLIS.]

Baltimore is one of the most important commercial cities in the United States. [BALTIMORE.]

Cumberland, situated on the north bank of the Potomac and on the Baltimore and Ohio railway, 134 miles W. from Washington, and 166 miles W.N.W. from Annapolis, contains a court-house, a gaol, a market-house, and several churches. It is the centre of an extensive trade in iron and coal, of which there are mines in the vicinity. Population, 6067.

Frederick, a city 54 miles N.W. from Annapolis, is well built, with wide and regular streets, and contains a court-house, gaol, county offices, several literary institutions, and twelve churches. A branch railway, 3 miles in length, connects it with the Baltimore and Ohio line. Population 8143.

Hagerstown, 26 miles N.W. from Frederick, is regularly laid out, and contains a handsome court-

house, a town-hall, masonic hall, and nine churches, Population 3750.

History and Constitution.—Maryland was first settled as a place of refuge for the persecuted Roman Catholics of England by Lord Baltimore in 1634, and the country received the name of Maryland from Henrietta Maria, the wife of Charles I. It was admitted into the Union in 1788, but the constitution of the state was remodelled in 1851. In the late civil war the first blood was shed in Maryland, several Massachusetts volunteers having been killed at Baltimore on their way to Washington. The sympathies of the state were with the Confederates, but its position with reference to the seat of the Federal government caused it to be occupied by a strong military force, and placed under martial law. It was repeatedly invaded from Virginia and made the scene of several bloody conflicts. The legislative body consists of twenty-two senators, who are elected for four years, and seventy-four representatives, who are elected for two years. The governor is elected for four years. Maryland sends two senators and six representatives to Congress, and has eight votes for the election of president of the United States.

A state penitentiary and asylum for the insane have been erected at Baltimore.

MARYGOLD. [CALENDULA.]

MARYPORT. [CUMBERLAND.]

MASANIELLO. [ANIELLO.]

MASCARENHAS. [BOURBON, ISLE OF.]

MAS-D'AZIL. [ARIÈGE.]

MASÈRES, FRANCIS, was born in London, December 15, 1731. His father was a physician, descended of a family which was driven out of France by the revocation of the Edict of Nantes. He was educated at Clare Hall, Cambridge, and took the degree of B.A. in 1752, having gained the highest place, both in classics and mathematics. Having obtained a fellowship in his college, he removed to the Temple, was in due time called to the bar, and went the Western circuit for some years with little success. He was then appointed (about 1763) attorney-general for Canada, in which province he remained till 1770, distinguished by his loyalty during the American contest, and his zeal for the interests of the province. On his return to England he was appointed cursor baron of the Exchequer, which office he held till his death. He was also at different times deputy recorder of London and senior judge of the sheriff's court. He died May 19, 1824, at Reigate, in the ninety-third year of his age.

Baron Masères (as he was commonly called) has acquired celebrity partly from his own writings, and partly from the munificence with which he devoted a part of his income to reprinting such works as he thought useful, either in illustration of mathematical history or of that of his own country.

Of these reprints the most important is the 'Scriptores Logarithmici,' a collection in six volumes quarto, published in various years from 1791 to 1807, of writings on the subject of logarithms. Here we find the works of Kepler, Napier, Snell, &c., interspersed with original tracts on kindred subjects. The republication of these old writings has brought them within reach of many students to whom they would otherwise have been inaccessible, and has thus tended to promote historical knowledge and to excite inquiry.

The 'Scriptores Optici,' 1823, a reprint of the optical writings of James Gregory, Descartes, Schooten, Huyghens, Halley, and Barrow, has a merit of the same kind.

MASHAM, ABIGAIL, was the daughter of Francis Hill, a merchant of London, who married the sister of Mr. Jennings, the father of the duchess of Marlborough. Her relative, then Lady Churchill, procured her the place of waiting-maid to the Princess Anne. She retained her situation after the princess ascended the throne, and acquired great influence over her. Miss Hill married Mr. Masham (son of Sir Francis Masham, of Otes in Essex) in 1707. Harley, afterwards earl of Oxford, connected himself with the new favourite; a change of ministry took place, and in 1711 Mr. Masham was raised to the peerage. He and his wife appear to have been engaged in the intrigues of the Tories in favour of the exiled House of Stuart. Lady Masham lived a long time after the death of the queen, and died at an advanced age, December 6, 1734.

MASHING. [DISTILLATION.]

MASKELYNE, NEVIL, was born in London, October 6, 1732, was educated at Westminster, and afterwards at Catherine Hall and Trinity College, Cambridge, in which university he took the degree of B.A., with distinction, in 1754. In 1755 he took orders, but he had previously been led to turn his attention to astronomy by the solar eclipse of 1748, and by his acquaintance with Bradley, whom he assisted in the formation of his tables of refraction. In 1761 he went to St. Helena, to observe the transit of Venus, and to detect, if possible, the parallax of the fixed stars. In this voyage, and in one undertaken to Barbadoes, in 1764, to try the merits of Harrison's new chronometers, he acquired that knowledge of the wants of nautical astronomy which afterwards led to the publication of the Nautical Almanac. In 1765 he was appointed to succeed Mr. Bliss as astronomer royal, and from this time, with the exception of his journey to Scotland in 1772, to determine the mean density of the earth by observing the effect of the mountain Schehallien, in Perthshire, upon the plumb-line, his life was one unvaried application to the practical improvement of astronomical observation. He died February 9, 1811.

Delambre dates the commencement of modern astronomical observation, in its most perfect form, from Maskelyne, who was the first to construct a standard catalogue (in 1790) of stars; that is, a number of stars observed with such frequency and accuracy, that their places serve as standard points of the heavens.

MASON BEE (*Osmia*), a genus of insects belonging to the family *Apidae*, or Bees. The species of this genus are noted for their habit of making their nests of small grains of sand, beautifully pierced and cemented together by a gummy secretion. The nests are placed in the corners of walls, in angles formed at the turns of brick walls, and similar situations. Another closely related form (*Megachile muraria*) carefully gathers the grains of sand from the earth with which they may be mixed, glues them together with its viscid saliva into masses the size of small shot, and carries them to their place in its jaws. Having laid a foundation, the walls of a cell are built, and in it an egg is deposited; then another is

made and filled in the same way; and so on till a cell is formed for each egg to be laid.

MASON, WILLIAM, born in 1725, was the son of a clergyman at Hull. He took his B.A. degree at Cambridge in 1745, after which he removed from St. John's College to Pembroke, of which college he was elected fellow in 1747. Having taken orders, he was presented to the rectory of Aston in Yorkshire, and became chaplain to the king. He died in 1797, aged seventy-two, having been for years precentor and canon-residentiary of York.

Mason's Poems are now little read. Two tragedies, 'Elfrida,' and 'Caractacus,' a descriptive poem called 'The English Garden,' and some odes, are his principal productions; but he is perhaps best remembered as Gray's biographer and friend.

MASONRY (from the French *maison* and *maçon*) signifies both the operation of constructing with stone and the parts of a building consisting of such material. It is a most important branch of architectural practice. Owing to its expense, masonry, until recently, was not much employed in England, except for public buildings or others of the highest class, the mason's work being in other cases restricted to such parts as steps to doors, string-courses, facias, and plain cornices externally, and to pavements and stairs in the interior.

The different kinds of stone used in masonry are noticed in the article *STONE FOR BUILDING*.

Walls which are not of solid masonry throughout, but built either of brick or inferior stone and rubble, with only an external facing of squared stone laid in courses, are termed *ashlar*, or *ashlaring*.

MASONS, FREE. [FREEMASONRY.]

MASORA, a Jewish critical treatise on the Hebrew text of the Bible. As the sacred books were originally written continuously, without even any breaks into words, the Jews found it necessary to establish a rule or canon to determine the exact reading, and this is called the Masora.

MASQUE or MASK, a species of drama which originated in the custom of enlivening processions and spectacles by the introduction of masked persons to represent imaginary characters. Gradually, in England, a dramatic form and poetic meaning were given to these shows, and finally they were performed with the aid of music, machinery, and decoration. They reached their climax of popularity in the reigns of James I. and Charles I., when Ben Jonson invested them with the splendour of his imagination, and Inigo Jones brought his taste and ingenuity to bear upon their stage presentment. One of the finest examples of this class of composition is, however, the work of a severer genius—we allude to Milton's 'Comus.'

MASQUERADE, an amusement introduced into England in the sixteenth century from Italy. It is distinguished from the masque by the general mingling of the company in dance and conversation, in place of the execution of a particular dance or preconcerted action by certain individuals. Granacci, who died in 1643, is said to have been the inventor of masquerades.

MASS. By the mass of a body is meant the quantity of matter which it contains, upon the supposition that differences of weight are always the consequence of different quantities of matter. This involves an hypothesis: for instance, if gold be, bulk for bulk, nineteen times as heavy as water, it is pre-

sumed that a given bulk of gold contains nineteen times as much matter as the same bulk of water.

MASS (*Missæ*, in Low Latin; *Missah*, 'an oblation or sacrifice,' in Hebrew) is a church service which forms an essential part of the ritual of both the Roman Catholic and Greek or Eastern churches, and in which the consecration of the sacramental bread and wine takes place. The congregation take no ostensible part in the service, but they follow it mentally, or in their prayer books, in which the text of the prayers is generally accompanied by a translation in the vulgar tongue. The priest does not address the congregation, but has his back turned to them, except at the end of certain prayers, when he turns round and says, '*Dominus vobiscum*' ('the Lord be with you'), and at the '*Orate, fratres*,' &c. ('brethren, pray,' &c.), which are responded to on the part of the congregation by the clerk. The Mass consists (1) of the preparation or introduction; (2) the consecration, both consisting of suitable prayers and invocations; (3) the communion, when the priest takes the sacrament in both forms and then descends from the altar and administers it to any of the congregation who wish to take it, but only in the shape of the consecrated wafer; (4) the *post communio*, consisting of a few more prayers, a blessing from the priest, and the reading of the first fourteen verses of the first chapter of John. The priest wears various vestments, the colours of which vary with the occasion. By the commandments of the church every Roman Catholic is bound, except in the case of illness, to attend mass once at least on Sundays and other holy days, and the transgression of this precept is reckoned a sin. Pious persons hear several masses in succession, and many attend mass every day in the week, for it is celebrated every day in each parish church; but except on Christmas day, no priest is allowed to celebrate it more than once unless by special dispensation. A priest must not break his fast, either by food or drink, from the previous midnight until he has said mass, out of respect for the real presence of 'Christ in the sacrament.' The service is, indeed, essentially connected with, and depends on, the doctrine of Transubstantiation. [SACRAMENTS.] It is held both in the Roman Catholic and Greek churches to be the sacrifice of the new law, a real, though unbloody offering, in which Christ is the victim, in substance the same with the sacrifice of the cross, and instituted as a commemoration of that sacrifice, and as a means of applying its merits through all ages for the sanctification of men. The Mass is performed entirely by the officiating priest standing before the altar, and attended by a clerk, who says the responses. The prayers of the Mass are all in Latin in the Roman Catholic church, in ancient Greek in the Eastern church, and in Syriac among the Maronites and Jacobites, but never in the vulgar or vernacular tongue of the country. The present service was the work of Gregory I. in the sixth century.

On great festivals and other solemn occasions the Mass is performed by a priest or prelate, attended by a deacon and subdeacon, who says the responses and chants the epistle and gospel of the day. On those occasions the Mass is sung, or at least parts of it, by a choir, accompanied by the organ and other musical instruments, and is called 'high mass.'

The 'Missale' is the name of the book which contains the ritual of the mass, and which the priest holds open before him on the altar. Some of the Old Missals, whether MSS. or printed, are beautifully ornamented with paintings, and are valued as bibliographic curiosities.

The Protestant and reformed churches have no mass, as they do not believe in the doctrine of Transubstantiation; but several of the detached 'Oremus' or prayers of that service, have been retained in the liturgy of the Church of England, translated into the vulgar tongue.

MASSA'CCIO, called *Tommaso Guidi*, was born at San Giovanni in Val d'Arno, in the year 1402, and died in 1428 or 1429. He was a disciple of Masolino da Panicci, to whom he proved as much superior as his master was to all his contemporaries. His most perfect works are the frescoes of S. Pietro del Carmine at Florence.

MASSACHUSETTS, one of the United States of North America, lies between $41^{\circ} 23'$ and $43^{\circ} 52'$ N. lat., and $69^{\circ} 50'$ and $73^{\circ} 10'$ W. long. The Atlantic Ocean washes its eastern and southern shores. On the south it is bounded by Rhode Island and Connecticut, W. by New York, and N. by Vermont and New Hampshire. Its greatest length is about 190 miles, and its greatest breadth 90 miles. The area is 7800 square miles. The population in 1865 was 1,250,000, of whom 10,000 were free coloured.

Surface and Soil.—The surface of this state is uneven; hilly and broken in the centre, east, and north-eastern parts, and level and sandy in the south-east. The western portion, though mountainous, does not attain to a very great elevation above the sea. Saddle Mountain, the highest land in the state, is 3505 feet; Mount Washington, 2624 feet; and Mount Wachusett, 2018 feet high. The east and south-east coasts are much indented with bays. The principal islands are Martha's Vineyard and Nantucket, which are noted for their whale and other fisheries.

Rivers.—The western and mountainous region is traversed by the Housatonic, which flows S. nearly 50 miles, when it enters Connecticut; it is a very rapid river, and not navigable in Massachusetts. The Connecticut enters Massachusetts from New Hampshire. [CONNECTICUT.] The Merrimac rises in New Hampshire on the western declivities of the White Mountains, and falls into the Atlantic after a course of more than 150 miles. The tide ascends to Haverhill, 15 miles from its mouth, but above it the course of the river is obstructed by several falls and rapids, all of which are now avoided by canals, and an uninterrupted navigation has thus been effected as far as Concord in New Hampshire.

Climate and Productions.—The climate of this state is much colder in winter, and warmer in summer, than the southern districts of Great Britain, though the difference of latitude amounts but to about nine degrees. In the spring it is subject to chilling north-east winds. The mean temperature is 48° , or two degrees less than that of London. In January the thermometer falls to 8° below zero; while in June it rises to 98° Fahr. The change of temperature is often 40° in twenty-four hours.

As Massachusetts was early settled, a greater por-

tion of its surface is cultivated than in most of the other states. The soil generally is rocky; and although the most approved systems of agriculture are adopted, and pursued with great industry, the corn produced is not sufficient for home consumption. The principal productions are Indian corn, rye, oats, potatoes, hemp, flax, peas, hops, beans, and pumpkins, which last are used as food for swine and cattle. Wheat, buckwheat, and barley are raised only in smaller quantities. All the fruit trees of England are cultivated. The fishery of cod in Massachusetts Bay and on the banks near Nantucket is important. Large quantities of mackerel are likewise taken.

Iron occurs in several places, and limestone abounds in the western parts of the state, where some good marble is found. Near the coast are numerous salt marshes. Much sand is used in glass manufacture.

Canals and Railroads.—Railways intersect the state, and connect all the large towns. There are altogether more than 1600 miles open. The conveyance of merchandise inland is also much facilitated by the Middlesex, Blackstone, Hampshire and Hampden, and Farmington canals.

Manufactures, Commerce, &c.—Massachusetts is one of the most enterprising states of the Union, and has very extensive manufactures of agricultural implements, general machinery, cotton, boots and shoes, and watches. There are also flourishing ship-building yards, and at least one-sixth of the United States Navy has been supplied by Massachusetts. The principal port is BOSTON, which is admirably screened from the storms of the Atlantic, and accessible to the largest vessels. The tonnage of all the vessels belonging to the state is over 800,000—nearly as much as that of the whole French mercantile marine. A large number of ships are employed in the whale fishery, chiefly from the port of New Bedford. The value of foreign imports into Boston in 1865 was 45,000,000 dollars.

Divisions, Towns, &c.—Massachusetts is divided into fourteen counties, which contain many large and important towns. The following are the principal, with the population in 1860 :—

Amherst, 82 miles W. from Boston, is the seat of Amherst College, a flourishing institution, with an observatory, and a good library of over 20,000 volumes. Population, 3052.

Andover, 22 miles from Boston, on the south-west side of the Merrimac, and on the Maine Railway, has 6748 inhabitants, some of whom are employed in manufactures of woollens.

Barnstable is a seaport town, 74 miles from Boston, on the south side of a bay of the same name, which opens into Cape Cod Bay, to which there is a branch railway. Population, 6000.

Boston is the capital of the state. [BOSTON.] *Cambridge*, *Charleston*, *Chelsea*, *Dorchester*, and *Roxbury*, are all contiguous to Boston, and joined to it by several bridges. They may therefore be regarded as suburbs of that city. *Cambridge* is the seat of Harvard University, the oldest in the United States, having been founded in 1638, with a museum, laboratory, botanic garden, and a library of about 140,000 volumes.

Dartmouth is 65 miles S. from Boston, and has many vessels engaged in the whaling and coasting trade.

Dedham, 13 miles S.S.W. from Boston, is situated on the Charles River, and has a gaol, court-house, and bank. Population, 4477.

Fall River, 51 miles S. from Boston, is a seaport on the Fall River, at its entrance into a branch of Narraganset Bay. The river affords splendid water-power, which drives many factories; and the town has also considerable shipping, and several banks. Population, 14,026.

Gloucester is 30 miles N.E. from Boston, near Cape Ann, on the Atlantic. It has a spacious and safe harbour, near the entrance of which are two lighthouses. The inhabitants number 10,904, and are mostly employed in navigation and the fisheries.

Lawrence is a town on the left bank of the Merrimac, 26 miles N. from Boston. In the course of a few years this place has risen from a mere village to a manufacturing town of considerable importance. In 1845 a dam across the Merrimac was constructed here, by which a fall of 28 feet of water was obtained; and a canal was formed for leading the water to the mills. There are now extensive linen, cotton, and woollen factories, and an iron foundry. Lawrence has also a town-hall, gaol, twelve churches, public schools, literary association, and two banks. The town was incorporated in 1847. Population, 8283.

Lexington, 11 miles N.W. from Boston, is a small town, which only requires notice as the place where the first blood was shed on the breaking out of the revolution—eight men having been killed by the British in an engagement on April 19, 1775. A monument has since been erected on the spot to commemorate the event.

Lowell is a city and manufacturing town, 25 miles N.N.W. of Boston, with which it communicates by canal and railway. It is situated on the south bank of the Merrimac, where the Concord River flows into it. Population in 1830, 6474; in 1860, 36,827. Lowell is the great seat of the cotton manufacture in the United States, for which there are upwards of fifty mills, employing 13,000 hands, of whom about two-thirds are females. It is often called the Manchester of America. The fall of the Pawtucket Canal—a descent of 32 feet, accomplished by four locks—affords immense water-power, by which most of the machinery of the mills, &c., is kept in motion. In the town are several churches; a high school, a grammar, and about thirty free schools; a lyceum; literary and mechanics' institutes, with library; three banks, and twelve incorporated companies; together with numerous private firms extensively engaged in the manufacture of cotton, linen, and woollen fabrics; bleacheries; powder-mills; and machinery. Among the publications of the city is a well-conducted magazine, the contributors to which are the young women of the factories. The general condition and morals of the workpeople are said to be highly satisfactory.

Lynn, 9 miles N.E. from Boston, on the shore of Massachusetts Bay, is a favourite place of resort for bathing in the summer season, and is famous for the manufacture of ladies' shoes, of which from 4,000,000 to 5,000,000 pairs are made annually. Population, 19,083.

Marblehead, 16 miles N.E. from Boston, situated on a rocky projection in Massachusetts Bay, is chiefly inhabited by fishermen. Population, 7647.

Nantucket, 119 miles S.S.E. from Boston, situated on the north side of Nantucket Island, at the bottom of the bay, has an excellent harbour. In and around the town are woollen cloth factories, rope-walks, felling and corn mills. Steamers ply daily to New Bedford. Population, 6094.

New Bedford, 55 miles S. from Boston, with which it is connected by a railroad, is situated near the western extremity of Buzzard's Bay. It contains a town-house built of granite, a court-house, custom-house, and many churches. The inhabitants are much engaged in the whale fishery, which employs from 300 to 400 ships; and there are also oil, soap, and candle factories, and cotton mills. Population, 22,300.

Newburyport, 38 miles N. by E. from Boston, is situated on the south bank of the Merrimac, at its entrance into the Atlantic. The custom-house is of granite, with a Doric portico. This town is connected with Boston by railway. The inhabitants, who are partly employed in the fisheries, number 13,401.

Northampton, 93 miles W. from Boston, situated on the west bank of the Connecticut, was incorporated as early as 1654.

Pittsfield, 151 miles W. from Boston, is situated on the line of railroad from Boston to Albany, and is 1000 feet above the sea. Manufactures of cottons, woollens, machinery, and fire-arms are carried on here.

Plymouth, a seaport, 38 miles S.E. from Boston, has a spacious but shallow harbour, a court-house, gaol, several churches, manufactures of cotton, and vessels employed in fisheries and in foreign trade. This is the oldest town in New England, having been the landing-place of the Pilgrim Fathers from the *Mayflower*, on the 22nd December, 1620. Population of the town, 6272.

Quincy, 9 miles S. by E. from Boston, is distinguished for the granite hills, which rise in some places to the height of 600 feet. A railroad extends from the quarry 3 miles to the tide-water on Neponset River, and was the first railroad made in the United States.

Salem, a city and seaport, 16 miles N.E. from Boston, was settled in 1628. It is situated on a tongue of land formed by two inlets from the sea called North River and South River. It contains a court-house, gaol, market-house, and many churches. There are also a lighthouse, tanneries, corn and saw mills, and railway stations; and the town is defended by two forts. Its East India trade is considerable; besides which it has an active coasting trade and whale fisheries. Salem is distinguished for its literary institutions and its commercial enterprise. Population, 22,252.

Springfield, 91 miles W. from Boston, on the east side of the Connecticut, contains one of the United States arsenals—the largest in the Union, employing 300 hands: 175,000 stand of arms are kept constantly in stock. It is also a great railway centre. Population, 15,199.

Worcester, 40 miles W. by S. from Boston, contains a court-house and several churches. The railroad from Boston to Springfield and Albany passes through it, and the Blackstone Canal connects it with Providence; besides which there is a railroad

to Norwich, in Connecticut. The town is noted for its schools and manufactures; and among its public buildings are a lunatic asylum and the hall of the American Antiquarian Society. Population, 24,960.

History and Constitution.—The first settlement was formed in 1620 at Plymouth, by about 120 families of English nonconformists, who had fled to Holland, and thence proceeded to Cape Cod. The American revolution began in Massachusetts. The first constitution was formed in 1780, and was revised and modified in 1820. The legislature consists of forty senators and 240 representatives, elected for one year. The governor is also elected annually. Massachusetts sends two senators and eleven representatives to Congress, and has thirteen votes in the election of the president of the United States. Every male citizen of the age of twenty-one years, who has resided one year in the state and six months in his election district, and who has paid a tax within two years, has a right to vote: he must, however, be able to read the Constitution of the state in the English language.

In the state are many churches of all denominations; and the educational establishments consist of 5 colleges, 3 theological seminaries, 2 medical schools, 70 incorporated academies, 800 unincorporated and private schools, and upwards of 4000 public or free schools. In fact, no state possesses greater facilities for the education of its inhabitants, and as a consequence it has given birth to many of the leading minds of America. Its charitable institutions are also on a most liberal scale; and in illustration of the general well-being of the people, it may be stated that in 1865 less than one per cent. of the inhabitants were either deaf and dumb, insane, blind, convicts, or paupers.

MASSÉNA, ANDRÉ, Prince of Essling, Duke of Rivoli, and Marshal of France, was born at Nice, May 6, 1758. Left an orphan at an early age, his education was greatly neglected. In 1775 he entered the army as a private soldier. After a diligent discharge of his duties for fourteen years he attained the rank of sergeant, but discouraged by this slow promotion, he retired to his native city, where he made an advantageous marriage. The breaking out of the French revolution recalled him to his former profession, and he was appointed adjutant-major of the battalion raised in the department of the Var, of which regiment he subsequently became colonel. In August, 1793, he was made general of brigade, and general of division a few months afterwards. In the Italian campaigns of 1794 and 1795 he served under the generals Kellermann and Scherer. When Bonaparte assumed the command of the army in Italy he employed Masséna actively on all occasions of importance. The scenes of his principal exploits were Montenotte (9–11 April, 1796), Millesimo (14 April), Castiglione (29 June–5 July), Arcola (15–17 November), and Rivoli (9 January, 1797). In February, 1798, he was appointed to the command of the army which, under General Berthier, was occupying Rome and the Papal States. Multiplied complaints of his avarice occasioned his recall, and he was left without employment till 1799, when the command of the armies of the Danube and of Switzerland was confided to him. In the direction of this campaign he evinced a military talent of the

highest order. On the return of Bonaparte from Egypt, Masséna was employed by him to defend Genoa. He arrived there on February 18, 1800, and defended it against superior forces, and amidst the horrors of famine, till June 3. On the same day that Napoleon became emperor, Masséna was created a marshal of France. In 1805 he was again appointed to the command of the army in Italy. After the peace of Pressburg (December 20, 1805), Masséna had the command of the army which was to conduct Joseph Bonaparte to Naples. In 1807 he was appointed to the command of the right wing of the army opposed to the Russians in Poland, and his services during this important campaign were rewarded by the title of Duke of Rivoli. He greatly distinguished himself at Landsbut and Eckmühl. At the battle of Essling the defence of the village of Aspern was committed to Masséna, and his services on that occasion were rewarded by the title of Prince of Essling. His operations also were highly effective at Engersdorf and at Wagram. Napoleon called him 'l'Enfant chéri de la Victoire' (Victory's favoured child). In 1810 Marshal Masséna was appointed to the chief command of the army in Portugal. His exploits in this campaign have not added to his reputation as a general, while the frequent examples of his cruelty, avarice, and breach of faith, have left a deep stain upon his memory. One achievement, however, his masterly retreat into Spain after the failure of his attempts on the lines of Torres Vedras, has been the subject of the highest praise and admiration.

Masséna was recalled from Spain in 1812. In 1813 he was sent to Toulon to take the command of the eighth military division, from which place he formally declared his adhesion to the Bourbons, on April 6, 1814, and was by them confirmed in his command. On the return of Napoleon from Elba, after some hesitation, he recognized his government. After Napoleon's second abdication he was appointed commander-in-chief of the national guard of Paris. Being a member of the council of war which was assembled for the trial of Marshal Ney, he joined the majority in declaring the incompetency of the court. He died April 4, 1817.

MASSILLON, JEAN BAPTISTE, was born June 24, 1663, at Hyères, in Provence, and at a very early age entered the Collège de l'Oratoire of that town. He took orders, and in 1696 was made director of the seminary of St. Magloire, at Paris. He preached two celebrated Lent sermons with great success before Louis XIV. and his court at Versailles. He was made bishop of Clermont in 1717. He died of apoplexy in 1742. His pulpit oratory was highly esteemed in France, and his sermons have great merit as compositions. The most interesting of his works, next to his sermons, are his 'Conferences.' Massillon's works were collected and published by his nephew, in 12 volumes 8vo, in 1745 and 1746.

MASSINGER, PHILIP, born at Salisbury, in 1584, was the son of one of the earl of Pembroke's retainers. In 1602 he was entered at St. Alban's Hall, Oxford, by that nobleman, with the view of being educated to become his chaplain; but his tastes inclining him to the study of poetry and romance, rather than to logic and philosophy, he was abandoned by his patron, and repaired to London, where

we first hear of him as the author of the 'Virgin Martyr,' which appeared in 1622. There is evidence also that after Beaumont's death he assisted Fletcher in the composition of some of his plays. During the rest of his life Massinger was employed in dramatic composition, and the last of his works appeared only six weeks before his death, which took place March 16, 1640, at his own house on the Bankside.

In 1759 a bookseller's edition of Massinger appeared, which was followed in 1761 by another; and in 1777 by a third, edited by Monck Mason. The best edition is that by Gifford, published in 1805. A one volume edition by Hartley Coleridge may also be commended. His 'New Way to pay Old Debts' still keeps the stage.

MASSINISSA. [NUMIDIA.]

MASSOWAH, a port in Abyssinia, on the Red Sea.

MAST of a ship is an upright spar of wood resting on the keelson, and rising through the decks to a considerable height, for the purpose of sustaining the yards upon which the sails are stretched. Masts are built of several pieces of wood, usually Norway fir, but of late sometimes of iron. The joints are strongly riveted together, and bound by iron hoops. These joints are respectively named the mast proper, and above this the topmast, the top-gallant mast, and the royal mast; the full height being about 240 feet in a first-rate man-of-war. A ship properly so called has three masts, named, according to position, fore, main, and mizen masts. A brig has a fore and a main mast, with top and top-gallant masts, and sails like those of a ship, but it has no mizen mast. A schooner has two masts, with no topsails; and a sloop only one.

MASTER and SERVANT. [SERVANT.]

MASTER AT ARMS, a petty officer of the Navy, who may be considered the head of the police of the ship; his assistants are called ships' corporals.

MASTER ATTENDANT, the officer next in rank to the superintendent of the royal dockyard.

MASTER OF A SHIP, in the Royal Navy, is an officer of inferior rank to the captain, commander, and lieutenants, who has charge of the ship's stores, and, under the orders of the captain, attends to the details of sailing the ship. On entering the service they are styled Masters' Assistants, and are paid at rates varying from 55*l.* to 75*l.* per annum. The next rank is second master, with pay varying from 90*l.* to 137*l.*, and then master, with pay according to length of service from 182*l.* 10*s.* to 365*l.* per annum. The title of Staff-commander has of late been given to the senior masters. In 1866 there were 286 staff-commanders and masters in the British Navy, the total charge for pay and allowances being 67,464*l.*; 199 second masters, charge 20,632*l.*; and 203 masters' assistants, charge 12,065*l.* In the merchant navy the master, called by courtesy the captain, is the commander of the ship, and has the sole management of it. Masters who have obtained certificates from the Board of Trade are eligible for the Royal Naval Reserve, with the rank of Lieutenant. [SHIP.]

MASTER OF ARTS. [ARTS, DEGREES IN.]

MASTER OF THE HORSE, one of the officers of the Court, who has superintendence of the royal stables and of all horses belonging to the sovereign.

The office is one of great dignity and antiquity, and is usually held by a nobleman. The salary is 2500*l.* a year, and the tenure of office depends on the existence of the political party in power. The Master of the Horse rides next to the sovereign on all state occasions, and has the privilege of making use of the royal horses, pages, and servants. In his department are eleven gentlemen equerries and four pages of honour.

MASTER OF THE HOUSEHOLD, an officer in the Lord Steward's department of the royal household. This office is held during the sovereign's pleasure, and is not dependent on political changes. The salary is 1150*l.* per annum, and the duties are the selection and management of the household servants.

MASTER OF THE ROLLS. [CHANCERY.]

MASTERS IN CHANCERY. [CHANCERY.]

MASTICH, a resin which is extracted from the trunk and branches of the *Pistacia lentiscus* by incision. This tree grows in the Levant, and particularly in the island of Chios. Mastich is composed of two resins, one of which is soluble in dilute alcohol, and the other is not; this last constitutes from 1-5th to 1-12th of the whole weight of the mastich, and possesses very nearly the characters of copal, it being soluble in absolute alcohol, ether, and oil of turpentine; these liquids also dissolve mastich without leaving any residue. Mastich is principally employed as an ingredient in varnish, and as a temporary stopping for carious teeth.

MASTIFF, the name of a variety of dog of a very old English breed, now seldom seen in its original state of purity. This is the *Dogue de Fort Race* of Buffon and the French, the *Mastivus* of Ray, and the *Canis molossus* of Linnæus. A true-bred mastiff is of considerable size, and very stoutly built. The head is well developed and large, the lips deep and pendulous on each side of the mouth, and the whole aspect noble. British mastiffs (though some think bull-dogs) were highly prized in ancient Rome for their prowess in the combats of the amphitheatre.

MASTODON, the name of an extinct genus of gigantic pachydermatous proboscidean Mammals (*Mastotherium*, Fischer), whose remains are found abundantly in the third and fourth, or pliocene, divisions of the tertiary fresh-water deposits, and also, but less frequently, in the deposits of the second or miocene period.

In the greater portion of their organization the Mastodons must have closely resembled the elephants. The tusks, the proboscis, the general conformation of the body and the limbs, were very similar; and the principal distinction between the two genera was formed by the molar teeth. These indeed were gradually pushed forward from behind as they are in the elephant, and displayed the same relative increase in proportion as the animal was advanced in life; but unlike those of the elephant, their crowns exhibited on cutting the gum large conical points of a mammiform structure, whence the animal derives its name. As these conical points were worn down by mastication, the tooth presented discs more or less large according to the degree of attrition which it had undergone.

The ascertained species are tolerably numerous, but the remains of the *Great Mastodon*, *Mastodon*

giganteus, Cuv., appear to have been the first that attracted attention. These occur in considerable abundance in North America. They gave rise to much speculation and much erroneous opinion, at first; for though the form and size of the molar teeth forbade the inference that they could have belonged to any of the large existing animals, the formidable appearance of the pointed conical tuberosities of the crowns led to conclusions directly the reverse of truth.

One of the principal deposits of Mastodon bones appears to have been the Big-bone Lick in the north part of Kentucky, near the Ohio. None of the remains have the appearance of having been rolled, but seem to have been unmoved since the death of the animal; and it is worthy of remark that those which were found at the river of the Great Osages, which runs into the Missouri a little above its confluence with the Mississippi, were in a vertical position, as if the animals had been bogged or buried in the mud.

Buffon seems to have been the first who noticed the occurrence of these teeth in the Old World, and figures one alleged to have been found in Little Tartary, and given to him by the comte de Vergennes. This is very large, having from eight to ten points, and weighing eleven pounds four ounces. He also figures another from the museum of the Abbé Chappe, said to have been brought from Siberia. Pallas announces another instance, and gives a figure of one from the Ural mountains. Cuvier states that he for a long time thought that his *Mastodon giganteus* inhabited the old Continent as well as America, but he confesses his doubts as to this point.

Example—*Mastodon giganteus* (Cuv.), *Mammuth Ohioticus* (Blum.), *Elephas carnivorus* (Gul. Hunter), *Mammoth* of William Hunter and of the Anglo-Americans. This animal must have equalled the elephant in height, but seems to have been longer and stouter in its proportion.

A magnificent skeleton of this species, as well as teeth and other relics in abundance, are contained in the British Museum.

MASOUD'Y, ABOU'-L-HASAN 'ALI' BEN-HUSEYN BEN-'ALI', one of the most celebrated Arabian writers, was born, according to his own statement, at Bagdad, in the third century of the Hejira, or the ninth of the Christian era. Masoud' was gifted with great talents, which he applied at an early age to learned pursuits. He gathered an immense stock of knowledge in all branches of science, and his learning was not mere book learning, but he improved it in his long travels through all parts of the East, Turkey, Eastern Russia, and Spain. He died at Cairo in A.H. 345 (A.D. 957).

No Arabian writer is quoted so often, and spoken of with so much admiration by his countrymen, as Masoudi, and although only a small portion of his numerous and voluminous works is known to Europeans, there is sufficient to show that he deserves his reputation.

MASULIPATAM, a seaport town in Hindustan, is situated on the eastern coast in 16° 10' N. lat., and 81° 14' E. long. About a mile and a half south-east from the town, is a fort in the form of a parallelogram, 800 yards long by 600 yards broad, and a straight causeway, 2000 yards long, connects the fort with the town. There are manufactures of

chintzes in the town and neighbourhood, considerable quantities of which are exported; they are much esteemed in Persia. This is the only part of the eastern coast of Hindustan on which the surf does not beat, and the harbour affords good anchorage for ships of 300 tons burthen. The town is 226 miles N.N.E. of Madras, and 1758 feet above the sea. Its population is 28,000. It is the capital of a district of the same name, the total population of which is 520,866, a part of whom are Hindus and Mussulmans. The trade of the place has latterly declined. The fort is surrounded by a salt morass, communicating by a canal with the Kistna and the sea. An extensive irrigation has been carried out by the government, at a cost of 241,000*l*. Rains are so precarious that at times the country is desolated. The district yields rice, millet, vegetables, tobacco, and cotton; the minerals are a little iron ore, and a few diamonds. The French established a factory at Masulipatam in 1750. It was taken by assault in 1759 by the English, under Colonel Forde, and has since continued in our possession.

MATADOR, the name given to the person who in Spanish bull fights inflicts the death-wound on the bull. After the *banderilleros* have goaded the animal to madness by fastening squibs upon him and discharging them, the matador advances with a naked sword and aims a fatal blow at him. If this is effectual, the slaughtered bull is dragged away and another brought forward.

MATAMORAS, or **EL REFUGIO**, a river port of Mexico, on the right bank of the Rio Grande, 40 miles from the Gulf of Mexico, is one of the most important ports in the empire. It exports specie, hides, wool, and horses; and imports manufactured goods, chiefly from Great Britain and the United States. The population of the town is about 15,000. On the 7th May, 1846, the United States troops defeated those of Mexico under the walls of Matamoras. In the late American civil war the port was much used for the purpose of forwarding goods to the Confederate states.

MATANZAS. [*CUBA*; *HAVANNAH*.]

MATARO. [*CATALUNA*.]

MATCH, in Gunnery, is a material employed in firing military mines or in discharging pieces of ordnance. Before the invention of fire-locks, hand-guns or small-arms were fired by matches, which the soldiers carried with them when on service; and matchlock fire-arms are still used in some remote parts of Asia.

What is called *slow-match* is only a piece of slightly twisted hemp which has been well soaked in a strong solution of saltpetre with boiling water. It burns very slowly; a piece a yard in length being scarcely consumed in less than eight hours. The materials employed in the formation of *quick-match* consist of a wick of cotton steeped in a mixture of saltpetre and meal powder with spirit of wine and rain-water.

MATCH-BOX. [*ARMS*.]

MATCHES. [*LUCIFER MATCHES*.]

MATÉ. [*PARAGUAY TEA*.]

MATE OF A SHIP. In the Royal Navy this title is now changed to *Sub-lieutenant*, and is the grade between lieutenant and midshipman. The pay is 5*s*. per day; and in 1866 there were 307

sub-lieutenants, the total charge for that year being 28,012*l*. The word *Mate* is now used when speaking of the assistants to the petty officers, as gunner's-mate, &c.

In the merchant service the first-mate ranks next to the captain, and commands in his absence, holding a position similar to that of lieutenant in the naval service.

The word *Mate* signifies a companion, equal, fellow-workman, or deputy, and in that sense is much used by the labouring classes.

MATELICA. [*MACERATA*.]

MATERA. [*BASILICATA*.]

MATERIA MEDICA, the division of medical science which treats of the knowledge of medicines, their action on the animal economy, and mode of administration. Much labour has been spent in contriving classifications of the materia medica. Some have arranged the articles according to their natural resemblances; others, according to their real or presumed virtues; others, according to their active constituent principles. Of old, the materia medica consisted of more articles than at present. The tendency is to diminish it still further, to get rid of those articles which possess no advantages over others equally common, or whose properties are doubtful.

MATERIALISM is a name applied to any philosophical system which denies the existence of a spiritual or immaterial principle in man, called the mind or soul, distinct from matter, or which (changing the phrase) denies the immateriality of the soul. The name is applied to systems which differ very widely from one another, in respect of the consequences deduced from the denial of the soul's immateriality: and thus it comes to pass that the popular meaning of the word has become loose and incorrect, comprehending what are no better than accidental consequences of the pure and proper idea. Such accidental consequences are the denial of a future state, and absolute atheism; and atheism and materialism are often treated in current conversation as convertible expressions.

The name 'materialism,' also, is one of that sort for which Mr. Bentham has invented the epithet *dyslogistic*. As applied in current conversation, it always carries with it censure. Indeed there is hardly a single word in the whole range of philosophic terminology better fitted to exemplify the evils of looseness of application or of allowing feelings to tinge and discolour the notions conveyed by names.

The following is a brief summary of the views of Dr. Priestley, who has more formally than any other writer enunciated the principles of materialism in the pure and proper sense of the word. He denies the existence of a separate immaterial principle in man, called the mind or soul, because he thinks that an immaterial principle could not exist in union with the material body, and because he thinks further that all mental phenomena (as they are called), may be explained by means of supposed movements arising out of the bodily organization. The method by which he thus explains mental phenomena is that of Hartley. [*HARTLEY*.] But, denying the existence of a soul, separate from the body, and capable of surviving when the body perishes, he does not yet deny the immortality of man, and a future state of rewards

and punishments. On the contrary, he distinctly affirms these on the authority of Scripture.

Materialism, even as it is expounded by Dr. Priestley, is devoid of philosophical foundation, and rests on a disregard of the limits of true philosophy. Its truth cannot be tested by observation. It rests altogether on hypothesis and conjecture. When we go beyond what are called the qualities of the mind, or of matter either, and speculate upon what it is itself, whether it is something else, or differing from that something, whether it has or has not an existence, we have no help but in supposing, and conjecturing, and imagining.

The converse of the word materialism is immaterialism. This is only used as an abstract term, and even thus very seldom; spiritualism being generally used in its place.

MATERIALS, STRENGTH OF, is the power that a solid body possesses of resisting forces tending to break it.

The *load*, or combination of external forces, which is applied to any piece in a structure or in a machine, produces *strain*, or alteration of the volume and figure of the whole piece, and of each of its particles. The strained particles exert *stress*, being an effort to recover their original volumes and figures; and the strain adjusts itself so that the combined stress of the particles balances the action of the load. If the load is continually increased, it at length produces either *fracture*, or (if the material is very tough and ductile) such a disfigurement of the piece as is practically equivalent to fracture, by rendering the piece useless.

The *ultimate strength* of a body is the load required to produce fracture in some specified way. The *proof strength* is the load required to produce the greatest strain of a specific kind consistent with safety; that is, with the retention of the strength of the material unimpaired. A load exceeding the proof strength of the body, although it may not produce instant fracture, produces fracture eventually by long-continued application and frequent repetition.

Each solid has as many different kinds of strength as there are different ways in which it can be strained or broken, as shown in the following classification:—

	Strain.	Fracture.
Direct	{ Extension ... Tearing.	
	{ Compression... Crushing.	
Transverse . . .	{ Distortion ... Shearing.	
	{ Twisting ... Wrenching.	
	{ Bending ... Breaking across	

A *factor of safety* is the ratio in which the ultimate strength or breaking load of a body is greater than the *working load*. For a *dead load* (that is, a load applied by slow degrees, and acting with perfect steadiness, like the weight of the structure itself) the factor of safety in the case of perfectly sound materials may be made simply equal to the ratio in which the ultimate strength is greater than the proof strength. For a *live load* (that is, a load put on suddenly, and accompanied with vibration and rapid motion, like a swift train on a railway bridge) the factor of safety is in general made twice as great, because the straining effect of a load suddenly applied is about twice as great as that of the same load when applied by slow degrees. In practice, the load

is usually partly dead and partly live; or its action is intermediate between that of an absolutely steady load and an absolutely sudden load; and accordingly, the factor of safety has intermediate values. A further allowance is in general made in the factor of safety to provide against unforeseen defects in the material or workmanship. The following are examples:—

	Dead Live Load. Load.
Factors for best possible materials and work, ...	2 ... 4
Factors for good ordinary materials and work—	
In iron and other metals, ...	3 ... 6
In stone and brick, ...	4 ... 8
In timber, ...	5 ...10

Most experiments on the strength of materials give the *ultimate strength* only. In using those data for the designing of structures and machines, the most convenient process of calculation is to multiply the intended *working load* of a piece by the proper factor, so as to find the *breaking load*, and to make the ultimate strength of the piece equal to that breaking load.

The *proof* or *testing* by experiment of the strength of a piece of material is to be conducted in two different ways, according to the object in view.

I. If the piece is to be *afterwards used*, the testing load must be so limited that there shall be no possibility of its impairing the strength of the piece; that is, it must not exceed the proof strength. About double of the working load is in general sufficient. Care should be taken to avoid vibrations and shocks when the testing load approaches near to the proof strength.

II. If the piece is to be *sacrificed* for the sake of ascertaining the strength of the material, the load is to be increased by degrees until the piece breaks, care being taken, especially when the breaking point is approached, to increase the load by small quantities at a time, so as to get a sufficiently precise result.

The *proof strength* requires much more time and trouble for its determination than the ultimate strength. One mode of approximating to the proof strength of a piece is to apply a moderate load and remove it, apply the same load again and remove it, two or three times in succession, observing at each time of application of the load the *strain* or alteration of figure of the piece when loaded, by stretching, compression, bending, distortion, or twisting, as the case may be. If that alteration does *not sensibly increase* by repeated applications of the same load, the load is within the limit of proof strength. The effects of a greater and a greater load being successively tested in the same way, a load will at length be reached whose successive applications produce increasing disfigurements of the piece; and this load will be greater than the proof strength, which will lie between the last load and the last load but one in the series of experiments.

It was formerly supposed that the production of a *set*, that is, a disfigurement which continues after the removal of the load, was a test of the proof strength being exceeded; but it is now known that in most materials a set is produced by almost any load, how small soever.

The strength of bars and beams to resist breaking across, and of axles to resist twisting, can be tested by the application of known weights either directly or through a lever.

To test the tenacity of rods, chains, and ropes, and the resistance of pillars to crushing, more powerful and complex mechanism is required. The apparatus most commonly employed is the hydraulic press. In computing the stress which it produces, no reliance ought to be placed on the load on the safety valve, or on a weight hung to the pump handle, as indicating the intensity of the pressure, which should be ascertained by means of an accurate pressure gauge. This remark applies also to the proving of boilers by water pressure.

The measurement of tension and compression by means of the hydraulic press is but an approximation. It may be sufficient for an immediate practical purpose; but for the exact determination of general laws, although the load may be applied at one end of the piece to be tested by means of a hydraulic press, it ought to be resisted and measured at the other end by means of a combination of levers.

The solution of all problems regarding the strength of materials depends on the following principle:—Conceive a piece of material which is acted on by a load distributed in any manner to be divided into two parts by a sectional plane. Then, if the strength of the piece is sufficient, the *external forces* acting on one of those two parts must be exactly balanced by the *stress*, or internal force, exerted upon each other by the particles at the two sides of that plane. This enables the amount of that stress to be determined; and when its mode of distribution is also known, its greatest intensity can also be determined; and according as that greatest intensity is within or beyond a certain limit, the strength of the piece is sufficient or insufficient at the section under consideration.

Tenacity.—The ultimate strength or breaking load of a bar exposed to direct and uniform tension is the product of the area of cross-section of the bar into the *tenacity* of the material. Therefore, let

P denote the breaking load, in pounds;

S the area of section, in square inches;

f the tenacity, in pounds on the square inch; then

$$P = fS; \quad S = \frac{P}{f}.$$

The following are some of the most useful values of the tenacity of materials, in lbs. on the square inch:—

METALS.

Bronze or gun metal (copper 8, tin 1),	36,000
Copper, cast,	19,000
“ sheet,	30,000
“ bolts,	36,000
“ wire,	60,000
Iron, cast, various qualities,	13,400 to 29,000
“ “ average British,	about 16,500
Iron, malleable: boiler plates,	50,000
“ “ large forgings,	40,000 to 50,000
“ “ bars, rods, & bolts,	50,000 to 70,000
“ “ wire,	70,000 to 100,000
Steel,	80,000 to 130,000

TIMBER.

Ash,	17,000
Fir and pine,	12,000 to 14,000
Oak,	10,000 to 19,800
Teak, Indian,	15,000

MISCELLANEOUS.

Hempen hawser, <i>girth in inches squared</i> ,	$\times 1,050$
Hempen cable, <i>girth in inches squared</i> ,	$\times 672$
Iron wire ropes, <i>per square inch of iron</i> ,	90,000
“ “ <i>per pound weight to the fathom</i> ,	4,480
Leathern belts, <i>working tension per square in.</i> ,	285
Silk fibre, <i>tenacity per square inch section</i> ,	52,200

The tenacity of a given material, *in lineal feet of itself*, is equal to the tenacity in lbs. on the square inch divided by the weight of a piece of the material a foot long and an inch square. The following are examples:—

Plate iron,	15,000
Bar iron,	18,000
Iron wire rope,	27,000
Charcoal iron wire,	30,000
Cast steel,	38,600
Hempen ropes,	from 18,000 to 27,000
Flaxen canvas,	21,000 to 32,000
Deal timber,	48,000
Teak timber,	54,000
Flaxen yarn,	52,000 to 59,000
Flaxen thread,	95,000
Silken thread,	120,000

Cylindrical Boilers and Pipes.—Let r denote the radius of a thin hollow cylinder, such as the shell of a high pressure boiler;

t the thickness of the shell;

f the tenacity of the material, in pounds per square inch;

p the intensity of the pressure, in pounds per square inch, required to burst the shell. This ought to be taken at *six times* the effective working pressure—*effective pressure* meaning the excess of the pressure from within above the pressure from without, which last is usually the atmospheric pressure, of 14·7 lbs. on the square inch or thereabouts.

Then

$$p = \frac{ft}{r};$$

and the proper proportion of thickness to radius is given by the formula—

$$\frac{t}{r} = \frac{p}{f}.$$

The tenacity of good wrought-iron boiler plates has been stated as 50,000 lbs. per square inch. That of a double-riveted joint, *per square inch of the iron left between the rivet holes*, is the same; that of a single-riveted joint somewhat less, as the tension is not uniformly distributed. It is convenient in practice to state the tenacity of rivetted joints in lbs. *per square inch of the entire plate*; and it is so stated in the annexed table. The joints of plate-iron boilers are single rivetted; but from the manner in which the plates break joint, analogous to the bond in masonry, the tenacity of such boilers is considered to approach more nearly to that of a double-riveted joint than that of a single-riveted joint.

Wrought-iron plate joints, double rivetted, the diameter of each hole being 3-10ths of the distance from centre to centre of holes,	85,700
---	--------

Wrought-iron plate joints, single rivetted, ...	28,600
Wrought-iron boiler shells, with single-rivetted joints properly crossed, ...	34,000
Wrought-iron retort, with a welded joint, ...	30,750
Cast-iron boilers, cylinders, and pipes (average British iron), ...	16,500

Spherical Shells, such as the ends of 'egg-ended' cylindrical boilers, the tops of steam domes, &c., are *twice as strong* as cylindrical shells of the same radius and thickness.

Thick Hollow Cylinder.—The assumption that the tension in a hollow cylinder is uniformly distributed throughout the thickness of the shell is approximately true only when the thickness is small as compared with the radius. The tension is in fact greatest at the inner surface of the cylinder; and it is at that surface that it first gives way when the pressure is greater than the material can bear.

Let R represent the external and r the internal radius of a thick hollow cylinder, such as a hydraulic press, the tenacity of whose material is f , and whose bursting pressure is p . Then

$$\frac{R^2 - r^2}{R^2 + r^2} = \frac{p}{f};$$

and, consequently,

$$\frac{R}{r} = \sqrt{\left(\frac{f+p}{f-p}\right)};$$

by means of which formula, when r , f , and p are given, R may be computed.

Thick Hollow Sphere.—In this case, using the same symbols as in the last Article, the following formulæ give the ratios of the bursting pressure to the tenacity, and of the external to the internal radius:—

$$\frac{p}{f} = \frac{2R^3 - 2r^3}{R^3 + 2r^3};$$

$$\frac{R}{r} = \sqrt[3]{\left(\frac{2f + 2p}{2f - p}\right)}.$$

Cylindrical Flues.—When a thin hollow cylinder, such as an internal boiler flue, is pressed from without, it gives way by *collapsing*.

The following formula gives approximately the *collapsing pressure* p , in lbs. on the square inch, of a plate-iron flue, whose length l , diameter d , and thickness t , are all expressed in the same units of measure:—

$$p = 9,672,000 \frac{t^2}{l d}.$$

When flues are strengthened by rivetting round them rings of T-iron, or angle iron, at equal distances apart, their strength is that corresponding to the length from ring to ring.

Resistance of Fastenings to Shearing.—In structures and machines cases occur in which the principal pieces, such as plates, links, or bars, being themselves subjected to a direct pull, are connected with each other at their joints by fastenings, such as rivets, bolts, pins, screws, cotters, or keys, which are under the action of a shearing force. It is in every such case important that the pieces connected and their fastenings should be of equal strength.

If the *shearing stress* were uniformly distributed

throughout the cross-section of a fastening, the ultimate strength of that fastening would be simply the product of its area into the ultimate shearing strength of the material. But owing to unequal distribution of the stress, the strength of fastenings may be reduced, for rectangular sections, to *two-thirds*, and for circular sections, to *three-fourths* of the greatest possible strength.

The following are the resistances of some materials to shearing, in pounds on the square inch:—

Cast iron, ...	27,700
Wrought iron, ...	50,000
Fir and pine, ...	500 to 800
Oak, ...	2,300
Ash and elm, ...	1,400

Resistance to Direct Crushing.—Direct crushing is produced by pressure in those cases in which the pillars, blocks, struts, or rods, along which the pressure acts, are not so long in proportion to their diameter as to have a sensible tendency to give way by bending sideways.

Let P denote the *crushing load* of the piece;

S the area of its transverse section in square inches;

f the resistance of the material to crushing, in lbs. on the square inch; then

$$S = \frac{P}{f}.$$

MATERIALS.	Crushing pressure, in lbs. on the square inch.
Brick, red, ...	550 to 1,100
Fire brick, ...	1,700
Granite, ...	5,500 to 11,000
Limestone, ...	4,000 to 4,500
Sandstone, ...	2,200 to 5,500
Rubble masonry, ...	4-10ths of cut stone.
Cast brass, ...	10,300
Cast iron, ...	82,000 to 145,000
" " average, ...	112,000
Ash (dry, along the grain), ...	9,000
Oak, elm, " "	10,000
Fir, pine, " "	5,400 to 6,200
Teak, Indian, " "	12,000

The resistance of timber to crushing, while green, is about one-half of its resistance after having been dried.

Resistance of Long Rods and Pillars to Crushing by Bending.—Pillars and struts whose lengths exceed their diameters in considerable proportions (as is almost always the case with those of timber and metal), give way, not by direct crushing, but by bending sideways and breaking across—being crushed at one side and torn asunder at the other.

Let P be the crushing load of a long rod or pillar, in lbs.;

S the sectional area of material in it, in square inches;

l , its length, } both in the same

h , its least external diameter, } units of measure.

Then, approximately—

$$P = \frac{fS}{1 + a \frac{l^2}{h^2}}.$$

The following are values of f and a , for pillars fixed at both ends, by having flat capitals and bases:—

	f , lbs. per inch.	a .
Wrought iron (rectangular), .	36,000 ...	$\frac{1}{3,000}$
Cast iron (hollow cylinder), .	80,000 ...	$\frac{1}{400}$
Timber (rectangular), . . .	7,200 ...	$\frac{1}{250}$

A pillar or rod rounded or jointed at both ends is as flexible as a pillar of the same diameter, fixed at both ends, and of double the length, and its strength is nearly the same. A pillar jointed at one end and fixed at the other is as flexible as a pillar of the same diameter, and of once-and-a-third the length; and its strength is nearly the same.

In wrought-iron framework and machinery, the bars which act as struts, in order that they may have sufficient stiffness, are made of various forms in cross-section, well known as 'angle iron,' 'channel iron,' 'T-iron,' 'double T-iron,' &c. For each of those forms, the constant a is to be diminished in the ratio in which that form is less flexible than a plain rectangular section.

Wrought-iron cells are rectangular tubes (generally square) usually composed of four plate-iron sides, rivetted to angle-iron bars at the corners. The ultimate resistance of a single square cell to crushing by the buckling or bending of its sides, when the thickness of the plates is not less than one-thirtieth of the diameter of the cell, is about 27,000 lbs. per square inch section of iron; but when a number of cells exist side by side, their stiffness is increased, and their ultimate resistance to a thrust may be taken at 33,000 to 36,000 lbs. per square inch section of iron. The latter co-efficients apply also to cylindrical cells.

Resistance to Cross-breaking.—Bending and cross-breaking are produced by a transverse load. A piece of material subjected to a transverse load is called, in general, a *beam*. The simplest case of a transverse load is when three parallel forces applied to a beam balance each other. In order that they may balance each other, the middle force must act in the contrary direction to the two endmost forces; and each of the three forces must be proportional to the distance between the other two. For example, the middle force may be a weight resting on the beam, and the endmost forces the upward pressures exerted by two props that support it; or the endmost forces may be weights resting on the beam, and the middle force the upward pressure exerted by a prop. The external forces that act upon a beam having been determined, the straining actions which they exert at a given cross-section of the beam are found as follows:—Consider all the external forces which act on one only of the two parts into which the cross-section divides the beam, and take their resultant; this will be the *shearing action* at that cross-section; and the particles at the cross-section ought to be able to exert an equal and opposite *shearing stress*. Then take the *resultant moment* of the same external forces; that is, multiply their resultant by its leverage, or perpendicular distance from the given cross-section; this will be the *bending moment* exerted at the given cross-section; and the particles at that cross-section ought to be able to exert an equal and

opposite *moment of resistance*. The moment of resistance is produced in the following manner:—When the beam bends, one side of it becomes compressed and the other stretched. In general, the side towards which the middle external force acts is stretched, and the other side compressed; for example, when a beam is loaded in the middle and supported at the ends the lower side is stretched and the upper compressed; and when a beam is supported in the middle and loaded at the ends, the upper side is stretched and the lower compressed. The stretched particles exert longitudinal tension, and the compressed particles an equal and opposite longitudinal thrust; and that pair of equal and opposite stresses, acting at the two ends of a lever whose length is a certain fraction of the depth of the beam, constitute a couple, whose moment (so long as the beam is strong enough) is equal and opposite to the bending moment exerted by the load at the given cross-section.

In practice, the strength of a beam against the shearing action of the load is in general more than sufficient; so that the bending moment and the moment of resistance are chiefly to be considered; and in particular, the bending moment and moment of resistance at that cross-section at which the bending moment is greatest. That cross-section is situated as follows:—

In a beam supported at both ends and loaded at any intermediate point, or supported at any intermediate point and loaded at the ends, the intermediate point;

In a beam supported at both ends, with an uniformly distributed load, the middle of the beam; and in a beam supported at the ends and loaded in any manner, the point which divides the load into two parts, respectively equal to the supporting pressures.

The *magnitude* of the load is most conveniently expressed in *pounds*, and the *leverage* in *inches*; so that the *bending moment* is expressed in *inch-pounds*.

In the following formulæ, W denotes the *total load*, in pounds;

c , in beams fixed at one end and free at the other, the *length of the free part*, in inches;

c , in beams either loaded or supported at both ends, the *half span*, between the extreme points of load or support and the middle, in inches;

M , the bending moment in inch-pounds.

For beams {	fixed at one end and loaded at the other, . . .	$M = cW$.
	fixed at one end and uniformly loaded, .	$M = \frac{cW}{2}$.
	supported at both ends and loaded at an intermediate point, whose distance from the middle of the beam is x , . .	$M = \frac{(c^2 - x^2) W}{2c}$.
	supported at both ends and loaded in the middle, .	$M = \frac{cW}{2}$.
	supported at both ends and uniformly loaded, .	$M = \frac{cW}{4}$.

If W be the intended *breaking load* of the beam,

G G

found by multiplying the working load by a proper factor of safety, M will be the *moment of rupture*, to which the *moment of resistance to rupture* at the place where the tendency to break is greatest must be made equal.

That moment of resistance is given by the formula—

$$M = n f b h^2;$$

in which

b denotes the extreme breadth of the piece, in inches;

h its extreme depth, in inches;

f a factor depending on the material, called the *modulus of rupture*, in pounds on the square inch;

n a factor depending on the figure of the cross-section.

M having been computed from the breaking load and its leverage, and f and n being known, the transverse dimensions of the beam are to be such that

$$b h^2 = \frac{M}{n f}.$$

It is obvious that the breadth and depth may be varied, and still give the product $b h^2$ the same value; but there are limits to that variation founded on considerations of stiffness and stability.

The following table gives examples of the values of the factor n for some of the more usual forms of cross-section:—

I. Rectangle $b h$ (including square), . . .	$\frac{1}{6}$.
II. Ellipse, vertical axis h , horizontal axis b (including circle, for which $b = h$), . . .	0.0982
III. Hollow rectangle, $b h - b' h'$; also I-formed section, where b' is the sum of the breadths of the lateral hollows, . . .	$\frac{1}{6} \left(1 - \frac{b' h'^3}{b h^3} \right)$.
IV. Hollow square, $h^2 - h'^2$	$\frac{1}{6} \left(1 - \frac{h'^4}{h^4} \right)$.
V. Hollow ellipse, . . .	0.0982 $\left(1 - \frac{b' h'^3}{b h^3} \right)$.
VI. Hollow circle, . . .	0.0982 $\left(1 - \frac{h'^4}{h^4} \right)$.

MODULUS OF RUPTURE, IN LBS. ON THE
SQUARE INCH.

Wrought iron, plate beams	f , 42,000
“ “ bars and axles, ...	54,000
Cast iron, ...	$18,750 + 23,000 \frac{H}{h}$,
(where H is the <i>depth of solid metal</i> in the section of the beam, and h the <i>extreme depth</i> .)	
Ash, ...	12,000 to 14,000
Fir, pine, ...	7,000 to 12,300
Larch, ...	5,000 to 10,000
Oak (British, Russian, and American), ...	10,000 to 13,600
Teak, ...	14,800

The modulus of rupture is *eighteen* times the load required to break a bar one inch square, supported at two points one foot apart, by being applied in the middle of the bar.

Some beams tend to break by tearing at the stretched side, and some by crushing at the compressed side, according to the nature of the material and the figure of cross-section; so that the modulus of rupture represents in some cases the tenacity of the stretched side, and in others the resistance of the compressed side to crushing. When the form of cross-section is similar above and below, the beam gives way by tearing or by crushing, according as the tenacity or the resistance to crushing is the smaller; thus, in general, wrought-iron beams and timber beams give way by crushing, and cast-iron beams by tearing. Economy of material makes it desirable that the tendencies to give way by crushing and by tearing should be as nearly as possible equal; and this is accomplished by making the cross-section more massive in form at that part which is exposed to the kind of strain against which the material is weaker. For example, if the beam consists of a vertical web with a pair of flanges along its edges, the stretched flange is made the larger, in cast iron, in the ratio of 5 or 6 to 1, and the compressed flange in wrought iron, in the ratio of 4 to 3 or of 5 to 4.

Resistance to Wrenching.—For equal values of the modulus of rupture, denoted by f , the strength of a cylindrical axle to resist wrenching is double of its strength to resist breaking across. A square shaft is stronger against wrenching than a round shaft of the same diameter, in the ratio of 10 to 7, nearly.

The modulus of rupture by wrenching is the same, or nearly the same, with that of resistance to shearing.

Stiffness and Resilience of Materials.—In many cases it is necessary to consider, not merely what state of stress will be produced in a given piece of material by a given load, but also what alteration of figure will be produced. The property of resisting alteration of figure is called *stiffness*, and is expressed as a quantity by dividing the intensity of a stress by the fraction expressing the corresponding strain, or proportionate alteration of dimension. The quotient is called a *modulus of stiffness*, or of *elasticity*.

The quantity of mechanical work done in straining a piece of material up to its proof strength, is found by multiplying half the proof load by the extent to which the material yields at the point where the load is applied. This is called the *resilience* of the material; it is proportional to the square of the proof strength divided by the stiffness; and it represents the power of bearing shocks.

A structure should neither be so yielding as to make it when loaded assume a shape unfit for its purpose, nor so stiff as to make it deficient in resilience.

The strain or yielding of a piece of material, so long as the load does not exceed the proof strength, increases nearly in the simple ratio of the load; in other words, the modulus of elasticity is sensibly constant; but when the load exceeds the proof strength, the strain increases faster than the load. The values of moduli of elasticity given in tables are all for loads not exceeding the proof strength.

Moduli of elasticity are of different kinds, according to the way in which the piece of material is strained. The kind which is of most use in practice, and which is always meant when not otherwise specified, is the modulus of *direct elasticity*, or of resistance to direct lengthening or shortening of a

bar by a direct pull or thrust. It is found by dividing the intensity of the stress by the fraction expressing the proportionate alteration of length produced. The following are examples:—

MATERIAL.	Modulus of direct elasticity, in lbs. on the square inch.
Steel, ...	from 42,000,000 to 20,000,000
Malleable iron, ...	29,000,000 " 20,000,000
Cast iron, ...	23,000,000 " 12,000,000
Teak timber, ...	1,900,000
Oak, ...	2,400,000 " 1,200,000
Pine and fir, ...	1,800,000 " 1,400,000
Ash, ...	1,900,000 " 1,600,000

The following are examples of the chief uses of the modulus of direct elasticity. Let it be denoted by E , and let p be the proof stress. Then

$$\begin{aligned} \text{Proof extension of a bar, in fractions of its length,} &= \frac{p}{E}. \\ \text{Resilience of a bar under tension, of length } l \text{ and cross-section } S, &= \frac{p^2}{2E} lS. \end{aligned}$$

Let h be the depth of an originally straight beam; r the radius of the sharpest curvature to which it can be bent without injury; p the proof tension; and t the proof thrust at the cross-section where the curvature is sharpest; then

$$\frac{r}{h} = \frac{E}{p + t}.$$

Let c be the half span of the beam; then the deflection under the proof load is—

$$\begin{aligned} \text{For a beam of uniform section, supported at the ends, loaded in the middle,} & \frac{c^2}{3r}; \\ \text{For a beam of uniform section, supported at the ends, uniformly loaded,} & \frac{5c^2}{12r}; \\ \text{For a beam of uniform depth; the breadth at different parts of the span made to vary proportionally to the bending moment,} & \frac{c^2}{2r}. \end{aligned}$$

The modulus of transverse elasticity expresses the relation between the intensity of the shearing stress exerted by a particle and the corresponding distortion of that particle. The following are examples:—

MATERIAL.	Transverse elasticity, in lbs. on the square inch.
Malleable iron, ...	about 9,000,000
Cast iron, ...	" 2,850,000

Its chief use is, in connection with the strength of materials, to calculate the angle of proof torsion of a cylindrical rod; that is, the angle through which such a rod is twisted by a twisting moment that produces the proof stress on its outside particles. Let q be that stress; C the modulus of transverse elasticity; l the length of the rod; d its diameter; then the required angle, in circular measure (that is, are to radius unity), is $\frac{2ql}{Cd}$.

(For detailed information on the strength of materials, reference may be made to the following authorities, amongst many others:—Tredgold's *Carpen-try*; Tredgold and Hodgkinson on the *Strength of Cast Iron*; Barlow on the *Strength of Materials*; Kirkaldy on the *Strength of Iron and Steel*; Fairbairn on *Iron*; Fairbairn's *Useful Information*;

MATHEMATICS ($\mu\acute{\alpha}\theta\eta\sigma\iota\varsigma$ or $\mu\acute{\alpha}\theta\eta\mu\alpha$), a name given in the first instance to a branch of knowledge, not as descriptive of its subject-matter, but of the methods and consequences of learning it. The word $\mu\acute{\alpha}\theta\eta\sigma\iota\varsigma$, and the Latin *disciplina*, by which it has been rendered, have been the origin of the vernacular terms *mathematics* and *discipline*, the meanings of which have long since separated. The properties of space and number, the subject-matters of the $\mu\acute{\alpha}\theta\eta\sigma\iota\varsigma$, have usurped the name; so that anything which relates to them, however learnt, is called mathematics: the Latin word, on the contrary, still retains the signification of a corrective process; and in speaking of any branch of knowledge, is applied when power of mind is derived from the methods of learning it, as well as knowledge from the results.

The distinction between the old and new meaning of mathematics is most requisite to be kept in mind, because arguments are frequently urged for and against mathematics, in which the discipline is confounded with the communication of facts and processes about space and number.

In the time of Plato, which was probably that of the application of words which imply 'the discipline' to that one exercise of mind which consists in making deductions by pure reasoning from the self-evident properties of space and number, it is probable that such restriction of the word was easily justifiable. At present we have, besides mathematics, physics, the study of antiquity, grammar, &c., which have all been made disciplines, but no one of which was then entitled to that appellation. Nevertheless, it has happened that writers, misled partly by the name of mathematics and partly by the pre-eminence of mathematical reasoning in strictness and connection, have spoken as if it were the only cultivator of the pure reasoning power.

Much discussion has arisen upon the question whether those primary propositions which, from our clear apprehension and willing admission of them, are called self-evident, are notions inherent in the mind, or deductions of early experience. Except to mention this controversy, we have here nothing to do with it. The certainty of these propositions is all that we want, and this is conceded by both sides. The consideration, however, of the fundamental supports of mathematical reasoning is useful and interesting, and, as a safeguard, even necessary. It is not long since a school of metaphysicians existed, who imagined that because all mathematical definitions are precise, therefore the exact sciences are founded upon definition. It was not to them a necessary result of the constitution of our faculties that the three angles of every triangle make up the same amount, but a consequence of definition, which might have been something else, upon different suppositions. We can hardly undertake to explain what we do not understand, but we recommend every beginner in the subject to seek no knowledge about the character of fundamental propositions until he shall have become well acquainted with their consequences. He must take care to admit nothing which is not, or cannot be made, most evidently true; and

he will find that all axioms, as they are called, have the highest sort of certainty, namely, that they cannot be imagined otherwise.

Whatever may be the metaphysical hypothesis to which it is referred, it is certain that there is a real distinction between a mathematical assertion and one of any other kind. If we say that an unsupported bit of lead will fall to the ground, we state a fact of which we are as certain, in the sense of reliance, as we are of the other proposition that two straight lines cannot inclose a space. But in the former proposition, an exception, or even a permanent alteration of the law, is conceivable by the imagination: in the latter the mind would feel sensible of absurdity if it attempted to construct the idea of an inclosure bounded by only two straight lines. No distinctive phrases can be too strong to express the essential difference of these two assertions; but it is a misfortune that all terms which create a sufficient distinction are linked to one or another theory of the human mind. If the mathematical student can receive these terms as indicative of the difference of species, without bending before an hypothesis about the conformation of his own reason, he will do well to adopt them; if, on the other hand, he feel compelled to agree with any one system of mental philosophy, he will neither impede nor advance his mathematical career.

The sciences of which we speak may be considered either as disciplines of the mind, or as instruments in the investigation of nature and the advancement of the arts. In the former point of view their object is to strengthen the power of logical deduction by frequent examples; to give a view of the difference between reasoning on probable premises and on certain ones, by the construction of a body of results which in no case involve any of the uncertainty arising from the previous introduction of that which may be false; to form the habit of applying the attention closely to difficulties which can only be conquered by thought, and over which the victory is certain if the right means be used; to establish confidence in abstract reasoning by the exhibition of processes whose results may be verified in many different ways; to help in enabling the student to acquire correct notions and habits of generalization; to give caution in receiving that which at first sight appears good reasoning; to instil a correct estimate of the powers of the mind, by pointing out the enormous extent of the consequences which may be developed out of a few of its most inherent notions, and its utter incapacity to imagine, much less to attain, the boundary of knowledge; to methodize the invention of the means of expressing thought, and to make apparent the advantages of system and analogy in the formation of language and symbols; to sharpen the power of investigation, and the faculty of suggesting new combinations of the resources of thought; to enable the historical student to look at men of different races, opinions, and habits, in those parts of their minds where it might be supposed *a priori* that all would most nearly agree; and to give the luxury of pursuing a study in which self-interest cannot lay down premises nor deduce conclusions.

As instruments in the investigation of nature and the advancement of the arts, it is the object of the mathematical sciences to give correct habits of judg-

ment and ready means of expression in matters involving degree and magnitude of all kinds; to teach the method of combining phenomena, and ascending from the complicated forms of manifestation to the simple law which regulates them; to trace the necessary consequences of any law, assumed on suspicion, in order to compare those consequences with phenomena; to construct hypothetical representations of laws, or approximations to laws, which shall sufficiently represent phenomena; to convert processes of known accuracy but complicated operation, into others which make up in simplicity for a certain amount of inaccuracy, and to devise means for judging of that amount of inaccuracy, and confining it within given limits; to ascertain the most probable result of observations or experiments which are discordant with each other either from errors of measurement or unknown causes of disturbance; to point out the species of experiments which should be made to obtain a particular sort of information, or to decide between two laws which existing phenomena both indicate as of nearly equal credibility; to make all those investigations which are necessary for the calculation of results to be used in practice, as in nautical astronomy, application of force and machinery, and conduct of money transactions; in a word, though that word by itself would not have presented a sufficiently precise idea, to find out truth in every matter in which nature is to be investigated, or her powers and those of the mind to be applied to the physical progress of the human race, or their advancement in the knowledge of the material creation.

The main branches of mathematical science were formerly stated to be arithmetic and geometry, springing out of the simple notions of number and space. This is too limited a description. Unquestionably the science of numbers, strictly and demonstratively treated, and that of geometry, or the deduction of the elementary properties of figure from definitions which are entirely exclusive of numerical considerations, must be considered as the elementary foundations, but not as the ultimate divisions, of mathematics. To them we must add the science of operation, or algebra in its widest sense—the method of deducing from symbols which imply operations on magnitude, and which are to be used in a given manner, the consequences of the fundamental definitions. The leading idea of this science is operation or process. just as number is that of arithmetic, and space and figure of geometry: it is of a more abstract and refined character than the latter two, only because it does not immediately address itself to notions which are formed in the common routine of life. It is the most exact of the exact sciences, according to the idea of their exactness which is frequently entertained, being more nearly based upon definition than either arithmetic or geometry. It is true that the definitions must be such as to present results which admit of application to number, space, force, time, &c., or the science would be useless in mathematics, commonly so called; but it is not the less true that a system of methods of operation, based upon general definitions, and conducted by strict logic, may be made to apply either to arithmetic or geometry, according to the manner in which the generalities of the definition are afterwards made specific.

The most important question connected with the

mathematical sciences, is the manner in which they should be taught as disciplines of the mind. This concerns all who consider any branch of knowledge in that light; and as education spreads, this view of the subject will become of more and more consequence. Vitally essential as these sciences are to the advancement of the arts of life, we feel, in regard to this branch of their utility, in the situation of those who know that they must and will be attended to, because their cultivation is necessary to the supply of wants which all can feel, and the promotion of interests which all can understand. It is not so with the first-mentioned object of their study, but rather the reverse; for the wants of life being as easily supplied by the results of an illogical as of a logical system (provided only that vicious reasoning be not allowed to produce absolute falsehood), the facilities which laxity of reasoning affords in the mere attainment of results will always recommend it to those whose main object it is to apply the fruits of calculation to the uses of life. Such has been, and we are afraid will continue to be, the tendency of the great advance which the last century made in application.

All we should positively contend for is the necessity of making the entrance to the study as strict and rigorous as reason can make it, to all who are to receive liberal education. In the higher branches of mathematics many opinions prevail, and it would be impossible to make a formal standard of rigour. Add to this, that with a certain degree of experience in the estimation of reasoning, it may be comparatively immaterial which of several different methods is adopted; either may be rigorous if properly understood, and if the habit of reducing looseness of phraseology, or dangerous abbreviation of logic, to strict definition and formal deduction shall first have been well formed. To assist in gaining this end, we shall propose—

First, that no student should be allowed to enter upon the use of language in mathematical reasoning until he has acquired more acquaintance with the nature of assertion, denial, and deduction, than can be obtained from previous education as now given: this is to be done by the study of the elements of logic.

Secondly, that no consideration of facility or practical convenience should prevent the first study of arithmetic and geometry from being strictly demonstrative, and formally rigorous: rigour being defined to consist in explicit statement of every assumption, and logical treatment of every inference.

On the first of the preceding recommendations we shall only observe, that in order to distinguish between accurate and inaccurate inference, an acquaintance with the exact extent of meaning of the several modes of communication is absolutely necessary. This cannot be learnt from the ordinary use of language, which abounds in implications to be suggested by the circumstances of the speaker, the context of the words, or the tone in which they are delivered. Before the phrases of demonstration can be made to convey a meaning limited in both directions, the strict use of language must be made a study; if this be neglected, the words of any book may pass between the teacher and the learner, but no precaution has been taken to secure their conveying the proper meaning, neither too much nor too little.

On the second recommendation, we must first

explain that we hold many points of controversy very cheap, as far as they concern the discipline given by the most elementary branches of mathematics. It matters nothing, in our view of the case, whether an axiom be really incapable of proof, or whether the substitution of another would or would not place the science on a more simple basis. The habit to be formed is that of tracing necessary consequences from given premises by elementary logical steps: the premises to be true or false, the consequences to be true if the premises be true, and dubious (not necessarily false) if the premises be false. The only error which, at the stage in question, it is intended to avoid, is the deduction, as a necessary consequence, of that which is not so. The mind of the learner, however, is allowed to dwell too much at the outset on the absolute truth or falsehood of the conclusions, to the neglect of their connection with the premises: hence it arises that when a process occurs in which it is essential to examine that connection for its own sake, it is the universal complaint that beginners find difficulty and obscurity. From what other cause arises the dislike of the indirect demonstration? [ABSURDUM, REDUCTIO AD.]

Unfortunately for the mental progress of the student, he is often allowed to use premises of an easy form, in cases where a complete preparation for the subject would require more extended first principles, and greater prolixity of deduction. To this, as before observed, no objection can be taken in itself, provided that no consequences be admitted except the legitimate ones. But something more is admitted: the pupil is presented, in consideration of his attention to one set of premises, with the consequences of another, and is allowed to make believe that he has come fairly by the latter. Thus, by a theory which applies only to the ratio of number to number, he is permitted to draw general conclusions upon all ratios. When, in opposition, we advise that the first studies should be demonstrative and rigorous, we do not imply, for instance, that the more difficult system should in all cases be preferred to the less complete but more simple: we confine ourselves to insisting that whatever the premises may be, the conclusions should really follow; and that if the latter be necessarily of a limited character, the limitation should be stated.

The necessity of a demonstrative system of arithmetic is practically denied, in this country at least, by the use of a set of dogmatical rules. Such training would be less prejudicial if the notions of the student on reasoning were more settled, so that he could receive these rules with some fitting idea of their purpose, and of the extent to which they are to be considered as knowledge. As it is, he has no other view of arithmetic presented to him, and his conceptions of number are allowed to be first fettered, and afterwards led astray, by ideas derived sometimes from the reception of the conventional for the necessary, sometimes from modifications of truth which are convenient in practice though unsound in theory. Such an addition to his stock of mathematical power predisposes him to acquiesce in the shifts by which rigour is avoided in other parts of the science; and an arithmetic from which both sequence and accuracy of thought have been excluded is the asylum of geometry against truth, when the latter becomes too

difficult for an unenergetic, that is, untrained power of investigation.

MATHEW, REV. THEOBALD, commonly known as *Father Mathew*, the great apostle of temperance, was born at Thomastown, in Tipperary, on the 10th of October, 1790. He was educated at Maynooth, was ordained a priest of the religious order of Capuchins in 1814, and commenced his labours at Cork. Here he became the counsellor, physician, banker, and friend of the poor, and won their universal love and respect. He introduced the religious brotherhood of St. Vincent de Paul, founded large schools, and established a cemetery on the model of that at Père-la-Chaise. But the great work of Father Mathew's life is the marvellous reformation which he effected in the habits of his countrymen, by converting large numbers of them from drunkenness to sobriety. In 1838 he established in Cork a temperance society, which, owing to his great influence, soon counted 150,000 members. The fame of his eloquence and energy spread rapidly through the country, and he gradually extended the field of his labours to all the towns of Ireland, many of the principal ones of England and Scotland, and even to America. The greatest possible enthusiasm was everywhere excited, and the numbers who were induced to take the temperance pledge are almost incredible, amounting in many instances to 20,000, and even to 50,000 in one day. His association included a large proportion of the adult population of Ireland of all ranks and creeds. The change in the habits of the Irish people was so great that many of the breweries and distilleries were closed. His own relatives, who were distillers, were among the earliest and largest sufferers in this way. Father Mathew's fortune and resources were always exhausted by his philanthropic labours, munificent charities, and the enormous expenses connected with his great mission; and in his declining years he was largely involved in pecuniary difficulties. A pension of 300*l.* was granted to him from the civil list, and collections were made on his behalf in various parts of the kingdom. He died on the 8th of December, 1856.

An excellent biography of Father Mathew was written by J. F. Maguire, Esq., M.P. for Cork, and published in London, 1864.

MATHEWS, CHARLES, was born June 28, 1776. His father intended him for a bookseller, but the son felt an irresistible inclination for the stage, and after several successful provincial appearances, appeared at the Haymarket Theatre, London, in 1803. He subsequently became celebrated in those original entertainments called 'At Homes,' which he gave both in England and America with extraordinary success. He died June 28, 1835, at Devonport. He ranked high as a comedian and a mimic.

MATHIOLA, a genus of cruciferous plants, consisting of annual and perennial herbaceous plants inhabiting the warm countries bordering the Mediterranean, and extending eastwards into Persia and some of the southern Asiatic provinces of Russia. Between thirty and forty species are known to botanists, among which are those which form the Stocks and Gilliflowers of gardens, sweet scented biennials much valued for the beauty and variety of their many-coloured flowers. The principal source of these has been *Mathiola incana*.

MATICA or MATICO. This name is applied to an astringent plant brought from Peru, where it has long enjoyed a high reputation for its styptic properties. Doubts exist as to its botanical origin. Cold water extracts, in about four hours, all its medicinal virtues, and is an eligible means of administering it. A tincture is also employed, and the powdered leaves are given both internally and applied externally. It does not owe its astringent properties to tannin: and it seems to exert a vital action on bleeding vessels, so as speedily to arrest the hæmorrhage. It has been used to check other discharges, such as the profuse expectoration and also the night sweats of consumptive patients. Few drugs exert more than a temporary influence over these symptoms; but among such, Matico seems well entitled to attention.

MATINS (from the Italian *matina*, or the French *matin*, 'morning'), strictly the first part in the daily service of the Roman church. Matins or mattins, however, were divided into two parts, which were originally distinct offices and hours, namely, the *nocturn* and *matin lauds*. The *nocturns* or vigils were derived from the earliest period of Christianity. They originated in the endeavours of the early Christians to avoid persecution, by performing their 'holy mysteries' at night. The custom was afterwards retained from devotion and choice. The *matin lauds* followed next after the *nocturns*, and were supposed to begin with daybreak. We find allusions in the writings of Cyprian, and all the subsequent fathers, to the morning as an hour of prayer. About the end of the third or beginning of the fourth century there was public worship in the morning, as we learn from the 'Apostolical Constitutions,' which record the order of the service.

MATLOCK. [DERBYSHIRE.]

MATRASS, a glass chemical vessel, employed for the purpose of digesting, boiling, and distillation.

MATRICARIA, a genus of plants belonging to the natural order *Compositæ*. *M. Chamomilla*, Wild Chamomile, is common throughout Europe, on dung-hills, in cultivated ground, and on way-sides and waste places. It was formerly used as a medicine, but its place has been taken by the common Chamomile and other plants of the same order.

MATRICULATION (Lat. *matricula*) is a register kept of the admission of persons into any body or society of which a record is preserved. Among ecclesiastical writers mention is made of two kinds of *matricula*, the one containing a list of the ecclesiastics, called *matricula clericorum*; the other of the poor provided for at the expense of the church, called *matricula pauperum*. In modern times the term matriculation is chiefly applied to the enrolment of students at the different universities.

At Oxford every student admitted is entered on the books of some college or hall, where he commences residence immediately on matriculation at the university. The fees are as follow:—A servitor or bible clerk, 10*s.*; a peer, or the eldest son of a peer, unless he renounces his privilege of a shorter term of residence, 8*l.*; every other privileged person, unless he renounces his privilege, 5*l.*; every other person, 2*l.* 10*s.*

At Cambridge admission to a college is either by a personal examination before the tutors and officers, or through a recommendatory certificate specifying

the age, qualifications, &c., of the candidate, signed by a master of arts of either university, and accompanied by a deposit of caution-money to the extent of from 10*l.* to 50*l.* The matriculation fees for the common chest of the university are as follow:—nobleman, 15*l.* 10*s.*; pensioner, 5*l.*; fellow-commoner, 10*l.* 10*s.*; sizar, 15*s.*

At London University every student who proposes to graduate must pass an examination before matriculation. This examination takes place twice a year—on the second Monday in January and first Monday in July. The fee for matriculation is 2*l.*

At the Scottish universities matriculation consists in signing a promise of good behaviour and obedience to the rules. There is a uniform fee of 1*l.* paid at matriculation each year.

MATRIX, or **GANGUE**. Metallic ores are seldom found unmixed in the place in which they occur; they not only accompany each other, but are frequently associated with useless stony bodies, and these are called the matrix, or gangue.

MATSYS, **QUINTIN**, the blacksmith painter of Antwerp, was born at Louvain about 1460, and brought up as a smith, in which occupation he distinguished himself by fertility of invention and admirable workmanship. At Antwerp he fell in love with the daughter of a painter, who having refused to give her hand to any but a member of his own profession, Matsys abandoned the forge, studied art under Roger Van der Weyden, and, inspired by love, rapidly rose into celebrity. He was married in 1491, and his first wife dying, re-married in 1508. His most famous works are—the so-called ‘Misers,’ at Windsor; a ‘Magdalene,’ at Corsham House, Wilts; and the ‘Descent from the Cross,’ in the Antwerp Museum. He died at Antwerp in 1530–31.

MATTER is the name for that out of which all objects external to the mind are thought to be composed, the question being reserved, whether the mind is or is not composed of the same substance. What this substance is to which the name of matter is given, we have no means of knowing. It is sufficient to know and say that man, subject to certain affections of his senses, is led to assign those affections to an external cause. This external cause is that which he calls matter; but all that is known of it is its capability of producing in him certain affections. When, therefore, we speak of the qualities of matter, we do not affect to say what that is which is the *substratum* of those qualities.

MATTHEW, **ST.**, the Apostle and Evangelist, was a native of Galilee, and a publican, or collector of customs and tribute under the Romans. While employed in his office at Capernaum he was called by Christ to follow him (Matt. ix. 9). The only further certain information which we possess concerning him is in the gospels. He is said to have preached the gospel subsequently in Persia and in Ethiopia, and to have died or been martyred at Naddabar in Ethiopia. An account which corresponds in all respects to that of the conversion of Matthew as related by himself is given by Mark (ii. 14), and Luke (v. 27), respecting a publican named Levi, the son of Alphaeus.

‘*The Gospel according to St. Matthew*,’ is a canonical book of the New Testament, ascribed by the unanimous consent of the early Christian writers

to the apostle Matthew. [GOSPEL.] It is generally considered to have been the first written, and most writers have fixed the date of this gospel about A.D. 38. There has been much discussion as to the language in which it was originally written, whether Hebrew or Greek. There may have been two originals, one in Hebrew for the Jewish converts, and one for general use in Greek. If there was only one, the probability is that it was in Greek.

MATTHEW OF WESTMINSTER, a monk of Westminster, and an old Latin chronicler of the time of Edward II. His work, which has come down to us, is entitled ‘Flores Historiarum.’ He begins with the creation, and the first half of the work is filled with the affairs of other countries, and of our own before the Conquest; the remainder contains a valuable account of our history from that period to the death of Edward I. An English translation is included in Bohn’s ‘Antiquarian Library.’

MATTHISSON, **FRIEDRICH VON**, was born at Hohendodeleben, near Magdeburg, January 23, 1761. In 1794 he obtained the appointment of reader and travelling companion to the reigning princess of Anhalt-Dessau, and during the next seven or eight years visited Italy, the Tyrol, and part of Switzerland, relative to which countries his ‘Briefe’ and his ‘Erinnerungen’ furnish many interesting details. His fame rests, however, on his ‘Elegy in the Ruins of an Old Castle,’ which is hardly less popular in Germany than that of Gray is with us, as is also his song of ‘Adelaide,’ with music by Beethoven. Matthisson also performed a good office for the poetical literature of his country by his ‘Lyrische Anthologie,’ a collection in 20 vols., published at Zürich, 1805–7. He died at Wörlitz, near Dessau, March 12, 1831.

MATTO GROSSO. [BRAZIL.]

MATY, **MATTHEW**, **M.D.**, was born in Holland in 1718, at Montfort, near Utrecht. He took his degree at Leyden and came to England in 1740. Through the popularity of his ‘Journal Britannique’ he was introduced to the leading literary men of the day, and had interest sufficient to obtain the post of principal librarian of the British Museum in 1772. He died in 1776. His works are ‘Mémoire sur la Caractère du grand Médecin, Boerhaave;’ ‘Authentic Memoirs of the Life of Richard Mead, M.D.’ At the time of his death he had nearly finished the ‘Memoirs of the Earl of Chesterfield,’ which was completed by his son-in-law, Mr. Justamond, and prefixed to that nobleman’s ‘Miscellaneous Works.’

MAUBEUGE. [NORD.]

MAUCHLINE. [AYRSHIRE.]

MAULÉON. [PYRÉNÉES, BASSES.]

MAUND, the name of a weight used in the East Indies, which varies in different provinces; but the ordinary Indian bazaar-maund is 82½ lbs. The Bombay maund is 28 lbs.; the Surat, 41 lbs.; the Madras, 25 lbs.; and the Bengal factory-maund, 74 lbs. 10 oz.

MAUNDY THURSDAY, the Thursday preceding Easter, so named from the *maunds*, or baskets, in which the alms or gifts made to the poor by our monarchs were formerly contained. These gifts were distributed to as many poor men and poor women as the sovereign numbered years, and consisted of victuals, clothing, and money. The lord high almoner,

and sometimes the monarch, formerly washed the feet of a certain number of the poor. James II. was the first who performed this ceremony. In 1838 a change was made in the maundy men and women receiving money from the clerk of the alms office instead of the accustomed fare.

The custom of the maundy is of considerable antiquity. Augustine, according to Du Cange, is first quoted for it. In England at least it was not entirely confined to royalty. In the earl of Northumberland's 'Household Book,' begun in 1512, folio 354, we have an enumeration of 'Almaner of things yerly geven by my lorde of his maundy, ande my laidis and his lordship's children.'

MAUPERTUIS, PIERRE-LOUIS MOREAU DE, was born at St. Malo, 17th July, 1698. Upon quitting the army, he applied himself assiduously to the study of the mathematics and astronomy. In 1723 he was admitted a member of the Royal Academy of Paris, and in 1727 a member of the Royal Society of London. In 1736 Maupertuis, in company with Clairaut, Camus, Lemoine, and Outhier, were deputed by the Academy to measure an arc of the meridian in Lapland. They were afterwards joined by the Swedish astronomer Celsius.

Maupertuis was one of the first among his countrymen who defended the Newtonian theory against the attacks of Descartes. When Frederick II. was about to re-organize the Academy of Berlin, he offered the presidency to Maupertuis, who accepted it. But his residence at the court of Prussia, which dates from 1745, seems to have been chiefly occupied in cultivating the good graces of Frederick, and he showed but little interest in scientific research. He died at Basle, 27th July, 1759, at the house of two of the sons of John Bernoulli, with whom he had always been on terms of friendship. His latter years were embittered by a dispute with Koenig, professor of mathematics at the Hague and foreign associate of the Academy of Berlin, respecting a mechanical principle of considerable importance, which Maupertuis appears to have been the first to promulgate, and from which he deduced the laws of the reflection and refraction of light, and those to which the collision of bodies are subjected, but of which he was unable to give any general demonstration. This principle, which he incorrectly designated 'the principle of least action,' he enunciated in terms identical with those employed at the present time. The Academy of Berlin, to whose arbitration the dispute was referred, decided in favour of Maupertuis, and ordered the name of Koenig to be erased from their list of associates; but even this decision, added to the support of the celebrated Euler, seemed inadequate to compensate Maupertuis for the raillery of Voltaire, who, although totally incompetent to judge on the scientific merits of the case, had taken the part of Koenig, and published his satirical piece entitled 'Diatribes du Docteur Akakia, Médecin du Pape,' wherein he was too successful in turning into ridicule both Maupertuis and his 'principle.' Frederick laughed at the satire, but ordered it to be burnt by the common executioner, which led to Voltaire's asking and obtaining permission to leave Berlin. ('Vie de Voltaire,' by Condorcet.) A list of the published works of Maupertuis is given in Quérard's 'Dictionnaire Bibliographique.'

MAUR, ST., CONGREGATION OF, a celebrated

society of Benedictines in France, who professed to follow the primitive rule of that order. It was first established in 1618. Among its more eminent members in the seventeenth century may be enumerated Hugh Menard, Luc d'Acheri, Jean Mabillon, Thierry Ruinart, and Bernard de Montfaucon.

MAURA, SANTA. [IONIAN ISLANDS.]

MAURIAE. [CANTAL.]

MAURICE OF NASSAU. [NASSAU.]

MAURICE, ELECTOR AND DUKE OF SAXONY, son of Duke Henry of Saxony, and grandson of Albert, surnamed the 'Courageous,' the founder of the Albertine line, a younger branch of the electoral family, was born in 1521. In 1542 he married Agnes, daughter of the landgrave of Hesse. Although a zealous Protestant, as his father had been, Maurice did not scruple to serve as a volunteer under the Emperor Charles V. 'Ambition,' says Voltaire, 'led him to second the views of the emperor, as ambition led him afterwards to denounce them.' This did not prevent him, however, from paying attention to home affairs. The laws which he established in 1543 are remarkable for their religious and moral bearing. Nor was he wholly under imperial domination; for when in 1542, at the suit of Henry, duke of Brunswick, who had been driven from his dominions, he was cited with the landgrave and the other confederates to appear before the Imperial Chamber, he publicly refused to acknowledge its jurisdiction, while composed entirely of men of a hostile religion, who had openly declared against keeping faith with 'heretics.'

On the breaking out of the war in 1545, between the duke of Brunswick and the landgrave of Hesse, the former applied to Maurice to intercede with his father-in-law to obtain peace. After repeated solicitations, he induced the landgrave to offer terms; but those offered involved so complete a submission on the part of the duke that they were indignantly rejected, and the war broke out afresh. It terminated, however, in the defeat of Brunswick, who, through the mediation of Maurice, was induced to surrender. The prince was accused of having acted a treacherous part in this transaction, and betrayed the duke; but he successfully cleared himself from the charge.

In 1546, on the breaking out of the war between the emperor and the Protestant confederates, John Frederick, elector of Saxony, and the landgrave of Hesse appeared on the latter side, for which they were duly outlawed by imperial authority. Meantime, Maurice had been secretly negotiating with the emperor and Ferdinand of Spain, the former of whom, as an inducement to support his cause, invited him to take possession of the electorate of Saxony. Maurice seems to have hesitated a little at this juncture; but some negotiations which he established with the Protestants led to no result, and he went boldly over to the emperor. During the long and active war which ensued, he distinguished himself greatly by his successes over his Protestant friends. In the following year (1547) the elector was taken prisoner at the battle of Muhlberg. Maurice and the elector of Brandenburg now interceded for the landgrave with the emperor, and by his permission they guaranteed the former his freedom, on condition that he surrendered and made an humble submission. But the emperor, less mindful of his allies' honour than his own interest, detained the landgrave in

prison, notwithstanding repeatedly reiterated remonstrances. Maurice had meantime received the electorate of Saxony from the emperor, and was solemnly invested therein in 1548.

In 1549 several charges having been made against him relative to his alleged attachment to popery, he refuted them in an able letter to his subjects. In 1550 he opposed the emperor through his representatives at the Diet at Augsburg, by protesting against the Council of Trent. In the same year he was appointed to the command of the imperial army which besieged Magdeburg, where he met with considerable success, although he seems to have been willing to favour the inhabitants as far as possible.

In 1551, on the emperor summoning the States to the Council of Trent, Maurice caused the heads of his doctrines to be drawn up by Philip Melancthon; but he refused to send his divines unless a safe conduct was granted them, not only by the emperor, but by the council itself—instancing the case of John Huss, in which the authority of the former had been set at nought. Towards the end of the year, he held a convention in his own states, to make peace with Magdeburg, which was eventually concluded.

In the meantime he had not forgotten the landgrave. After in vain praying the emperor for his restoration to liberty, he proposed to throw off a mask which had been long irksome to him. He accordingly entered into negotiations with the king of Denmark and many of the German states, and also with the king of France. Denmark and most of the states sent ambassadors to the emperor to mediate on behalf of the landgrave, but ineffectually; and Maurice now prepared for open hostilities. In 1552 he took the field with the Protestant princes, and achieved a brilliant campaign. The king of France had in the meantime made war upon the emperor, who, pressed on all sides, was eventually compelled to succumb. The result was the celebrated treaty of Passau, (August 12, 1552) which restored to the Protestants the free exercise of their religion, and the rights of which they had been deprived since the victory of Muhlberg.

Maurice now turned his arms against Albert, duke of Brandenburg, who had repudiated the treaty, and defeated him at Sievershausen in Luneburg, but fell mortally wounded in the engagement (July 11, 1553). He left behind him the renown of a sagacious statesman, a subtle diplomatist, a great captain. 'His was a nature,' says Ranke, 'like none other that Germany has ever produced—so secret, so enterprising, so energetic, so much a man of flesh and blood and not of mere ideas. The fate of Protestantism in Europe depended upon his actions: his desertion from its cause brought it to the verge of ruin; and his desertion from the emperor was the salvation of liberty.'

MAURITIUS, the Island of, called also ISLE DE FRANCE, is situated in the Indian Ocean, between 19° 45' and 20° 33' S. lat., and between 56° and 57° E. long. Its length is about 36 miles, breadth 20, and area 600 square miles.

The resident population of Mauritius on the 8th April, 1861, when the census was taken, was 310,050, the military amounted to 2350, and the crews in harbour to 1062, furnishing a grand total of 313,462—an excess over the census of 1851 of 129,956.

The Indian born population, exclusive of other Asiatics, numbered 172,425, the remainder being negroes, hill coolies, whites, and about 5000 British. The whites of the island are chiefly of French extraction, and speak the French language. The population, excluding the garrison and the shipping, was officially estimated on the 31st December, 1863, to be 323,254, as against 310,050 in 1861, as given above. In 1862 there were 13,986 emigrants, chiefly from India. The dependencies on Mauritius are Seychelles, the Chagos Archipelago, Rodrigues, and some other small insular groups, of which collectively the population was 9058 at the last census.

The island is surrounded by a coral reef, generally running parallel to the shores, at the distance of one or two furlongs, and mostly dry at low water. In this reef occur eleven breaks, by the greater number of which vessels of considerable burden may approach the island. The water between the reef and the shores, being less agitated than the open sea, affords facilities of communication between the places along the coast. The interior of the island consists of a great number of lofty hills, of which the Brabant mountains attain a height of 3000 feet, and Peter Botte Mountain presents an extraordinary shape. In the mountains at the back of Port Souillac and Grand Port is a small lake, which is considered to be an extinct crater. The rains and hurricanes are very violent.

This island was formerly covered with woods, and even now a considerable part of the native forest is allowed to remain for ornament round the plantations. The climate is healthy, the mean temperature of the year at Port Louis being 78°·7; in winter 75°, in summer 81°·8 Fahr. In some of the more elevated districts, however, the climate resembles that of the hills of India, and the thermometer usually stands 7° or 8° lower than at Port Louis. The surface is well watered, and the soil rich in the valleys, producing wheat, maize, yams, and manioc; but the principal product is sugar, the cultivation of which spread rapidly after the English obtained possession of the island; but since 1848 it has often greatly failed from an insect called the 'borer' attacking the canes. This insect is the great enemy of vegetable life, and for its extirpation a prize of 2000*l.* has been offered, but as yet no person has made the desired discovery. Another disease has also attacked the canes, which, when cut, prove destitute of juice and saccharine substance, though their outward appearance indicates health and ripeness. About 30,000 persons are employed on the sugar estates, of whom about 6000 are coolie immigrants from India. The total exports of sugar in 1863 amounted to 274,548,951 lbs., value, 2,494,556*l.*, being a slight increase on 1862, when the quantity was 268,162,351 lbs., worth 2,232,249*l.* The other articles of export are cotton, rum (358,399 gallons), oil, linseed, hides, copper (7000 cwts.), and specie (59,000*l.*), worth altogether 2,720,098*l.* in 1863. The principal articles imported in the same year were haberdashery, mercery, and millinery, and cotton manufactures, plain and coloured, worth altogether about 150,000*l.*; copper (8000 cwts.), wheat (38,000 qrs.), rice (1,284,790 cwts.), other grain, hardware and cutlery, machinery and mill-work, guano (22,000 tons), specie (301,758*l.*), and

wine. The total value of all the imports was declared to be 2,540,605*l.*, of which 569,084*l.*, only, came from the United Kingdom. Nearly half the exports, however, are sent to Great Britain. British vessels carrying 428,462 tons, and foreign ships carrying 182,808 tons, entered and cleared at the ports of this colony in 1863, the total being 611,270 tons. It is a strong proof of the endurance of national tastes in matters of food and clothing, that France still holds the third place as to imports, though she takes but an inconsiderable portion (about a ninth) of the produce of the island. The revenue in 1863 was 518,278*l.*, and the expenditure, 482,524*l.* A public debt of 600,000*l.* was incurred in 1863 for the construction of railways, some of which are now in working operation.

The government of the Mauritius and its dependencies is vested in a governor—whose salary is 7000*l.* a year—aided by an Executive and a Legislative Council, consisting of seven official and eleven non-official members, the latter chosen from the landed proprietors and principal merchants of the island. All their acts are subject to the approval of the British government. The principal towns in the island are Port Louis and Mahébourg. The total cost of the defences and garrison during the year 1863 was 137,500*l.*, of which about 31,000*l.* was defrayed by the colony. Mauritius was taken possession of principally for the protection of British trade in the eastern hemisphere, and its advantages as a coaling station in the direct line to India and China render its retention of more essential importance than ever in case of another maritime war. The roads generally throughout the island are excellent, and two or three lines of railway have very recently been constructed.

Horses are few, and seldom bred in the island. Mules and asses are more numerous, and principally used for the saddle. Cattle, goats, sheep, hogs, and fish abound.

Port Louis, the capital of the island, is situated near the north-western extremity, on a small bay called Port North-West, or Port Louis, which can accommodate a numerous fleet of ships. The town and harbour are strongly fortified, but the entrance to the latter is difficult, and during the hurricane months it is unsafe, except in an inner basin called the Panfaron. The population of the city in 1861 was 74,525, being an increase of 24,616 since 1851. The town has a Roman Catholic cathedral, a Protestant church, and two mosques, a citadel, barracks, bazaar, theatre, and royal college, with between 240 and 250 pupils. Since 1864 railways have been constructed from this port to the extremities of the island, and the town was recently lighted with gas. Among the public buildings may be mentioned the Governor's residence and government offices (which, however, are little better than sheds), central railway terminus, civil hospital, &c. The local affairs of Port Louis are managed by a municipal corporation, which is deeply in debt. In the city is a library containing more than 60,000 volumes, mostly French books; a good botanical garden; and some docks for the repair of vessels. There is another port in the southern part of the island called *Port Grand* or *Mahébourg*, which is not, however, much frequented, as it is encumbered with coral reefs, and difficult

of access for shipping. A lighthouse was erected near it in 1863. There is packet communication monthly between Mauritius and Ceylon.

Mauritius was discovered by the Portuguese in 1505. The Dutch surveyed it in 1598, and planted a settlement in 1640, naming it in honour of Prince Maurice, but they abandoned the island in 1708. In 1715 the French took possession of it, formed a settlement at Port North-West, and called the island *Isle de France*. They remained in its undisturbed possession to the year 1810, when it was taken from them by the British, who since the peace of 1814 have retained it. This island is the scene of St. Pierre's well-known romance of 'Paul and Virginia.' (*Governor's Reports; Colonial Blue Book, &c.*)

MAUSOLEUM, a term applied in modern times to a sepulchral chapel or edifice erected for the reception of a monument; but it originally designated the magnificent structure raised by Artemisia as the tomb of her husband Mausólus, king of Caria, at Halicarnassus, 352 B.C. Of this monument no remains now exist; but from Pliny's description it appears to have been nearly square in its plan, measuring 113 feet on its sides, and 93 on each of its ends or fronts, and to have been decorated with a peristyle of thirty-six columns (supposed by Hardouin to have been 60 feet high, or upwards), above which the structure was carried up in a pyramidal form, and surmounted at its apex by a marble quadriga executed by Pythis, who, according to Vitruvius, was joint architect with Sátyrus in the building. It was further decorated with sculptures and reliefs by Scopas, Bryaxis, Timotheus, and Leóchaes. The entire height was 140 feet.

The mausoleum erected at Babylon by Alexander the Great, in honour of Hephæstion, appears to have been still more magnificent. Those of Augustus, in the Campus Martius, and Hadrian at Rome, were structures of great magnitude and grandeur, and resembled each other in being circular in plan. Hadrian's is now converted into the *Castello di St. Angelo*, in which shape it is familiar to almost every one.

Such places as Henry VII.'s Chapel and the Pantheon of the Escorial may also be considered as mausoleums; but the term is generally restricted to a detached edifice erected merely as a private burying-place or to contain tombs. The queen has recently erected one at Frogmore, near Windsor, where the remains of the prince consort and the duchess of Kent have been interred; and a handsome edifice of this nature, which is said to have cost 100,000*l.*, adorns the grounds of the duke of Hamilton, at Hamilton, in Lanarkshire.

MAUVE. [DYING.]

MAVIS. The name given in Scotland to the *Turdus musicus*, thrush, or song-thrush, which inhabits every European country, being permanent in Britain and spread over the three kingdoms. It haunts gardens and woods near streams and meadows. Its song is sweet and has considerable compass; it can be made to repeat musical airs, and in some instances to articulate words.

MAXENTIUS, MARCUS AURELIUS VALE-RIUS, son of Maximianus, the colleague of Diocletian in the empire, was living in obscurity when, after his father's abdication, and the elevation of Constantine

to the rank of Cæsar, he became envious of the latter, and dissatisfied with the neglect of Galerius towards him. Accordingly he stirred up a revolt among the prætorian soldiers at Rome, and was proclaimed emperor in 306. He retained the imperial title and possession of Italy till 312, when he was defeated by Constantine, and was drowned in attempting to cross the Tiber. [CONSTANTINUS.]

MAXIMA and MINIMA. These Latin words, which simply mean 'greatest' and 'least,' are used to imply, not the absolute greatest or least values of a varying quantity, but the values which it has at the moment when it ceases to increase and begins to decrease, or vice versa. Thus if it be said that the height of the barometer was a maximum at ten o'clock, it means that up to that hour the barometer rose, and then began to fall; in which case it would still be said to have been a maximum, even though it should afterwards rise, and stand at a greater height than at ten o'clock. Thus it is possible that there should be several maxima and minima in one day, and even that one of the minima should be greater than one of the maxima: that is, at one moment when the fall ceases and a rise begins, the barometer may then be higher than it was at another time when a rise had ceased and a fall begun.

MAXIMIANUS, MARCUS AURELIUS VALERIUS, a native of Pannonia, born of obscure parents, served in the Roman armies with distinction, and was named by Diocletian his colleague in the empire in 286. The remainder of his life is given under DIOCLETIAN, CONSTANTIUS I., and CONSTANTINUS. He was put to death at Marseilles, by order of Constantine, for having conspired against his life, in 310.

MAXIMINUS, CAIUS JULIUS VERUS, was originally a Thracian shepherd. He was of gigantic size and great bodily strength. Alexander Severus gave him the command of a new legion raised in Pannonia, at the head of which he followed Alexander in his campaign against the Germans on the banks of the Rhine, where he induced some of his companions to murder Alexander in his tent, as well as his mother Mammaea, in 235.

Maximin, being proclaimed emperor, named his son, also called Maximin, Cæsar and his colleague in the empire. But his cruelty and rapacity aroused enemies against him in various parts of the empire. The province of Africa revolted, and proclaimed Gordian, who was soon after acknowledged by the senate and the people of Rome, in 237. On the news of the defeat of Gordian and his son by the Roman governor of Mauritania, the senate proclaimed emperors Clodius Pupienus Maximus and Decimus Cælius Balbinus, and Maximin was shortly afterwards killed in 238, by his own soldiers, while he was besieging Aquileia.

MAXIMINUS, DAIA, or DAZA, an Illyrian peasant, served in the Roman armies, and was raised by Galerius, who was his relative, to the rank of military tribune, and lastly to the dignity of Cæsar, in 303, at the time of the abdication of Diocletian and Maximian, when he had for his share the government of Syria and Egypt. After the death of Galerius, in 311, Maximin and Licinius divided his dominions between them, and Maximin obtained the whole of the Asiatic provinces. Valeria, the daughter of

Diocletian and widow of Galerius, having escaped from Licinius into the dominions of Maximin, the latter offered to marry her, and on her refusal banished her with her mother into the deserts of Syria. He persecuted the Christians and made war against the Armenians. A new war having broken out between Licinius and Maximin, the latter advanced as far as Adrianople, but was defeated, fled into Asia, and died of poison or despair at Tarsus, in 313.

MAXIMUS PLANUDES. [PLANUDES.]

MAXWELLTOWN. [KIRKCUDBRIGHT.]

MAY, the fifth month of our present year, was the second in the Old Alban calendar, the third in that of Romulus, and the fifth in the calendar of Numa Pompilius. In the Alban calendar it consisted of twenty-two days; of thirty-one in the calendar of Romulus; and of thirty in that of Numa. Julius Cæsar restored to it the odd day of which Numa had deprived it, and of which it still keeps possession. Its etymology is doubtful.

MAY, THOMAS, was born in 1595. In 1637 May was defeated by Sir William Davenant as candidate for the office of laureate, which the death of Ben Jonson had left vacant, which so exasperated May that he became a strong parliamentarian, wrote a history in favour of that party, and held office under it. In November, 1650, he was found dead in his bed. He was buried in Westminster Abbey, but, on the Restoration, his body was removed to a large pit in the churchyard of St. Margaret's, Westminster, and his monument pulled down.

MAY-APPLE, the *Podophyllum peltatum* of botanists, is a useful plant, with an agreeable fruit, but the leaves are poisonous and the root cathartic. It is chiefly cultivated for the sake of its active medicinal properties.

MAY-DAY. The first day of May; so called in England by way of eminence, in commemoration of the festivities which from a very early period were universally, and in many parts of the country are still observed. Many of the rites, such as pulling off branches of trees, adorning them with nosegays and crowns of flowers, dancing round a pole decked with garlands, had no doubt their origin in the heathen observances practised at this season in honour of Flora, the goddess of flowers.

MAY-DEW. The dew of May, which is said to whiten linen, and to afford by repeated distillations a red and odoriferous spirit.

MAY-FLY, the popular name of the *Nemopterus* insects of the genus *Ephemera* and its allies.

MAY-WEED (*Anthemis arvensis*, or Wild Chamomile), a troublesome weed in corn, which is difficult to eradicate, as it is propagated both by seed and by the low-running branches which strike into the soil and take root. It flowers in May, as its name denotes, and sheds its seed long before the corn is reaped. The only certain mode of extirpating it is by great care in clearing the land when it is fallowed or prepared for turnips, ploughing it in as soon as the flowers appear, and never allowing it to go to seed.

MAYENCE. [MAINZ.]

MAYENNE, a department in France, is bounded N. by the departments of Manche and Orne, E. by the department of Sarthe, S. by Maine-et-Loire, and

W. by Ille-et-Vilaine. It approaches in shape to a rectangle, 54 miles long by 40 wide. The area is 1988 square miles, and the population in 1861 was 375,163.

Surface and Products.—The surface of the department is strewed with hills, and in some places cut up by valleys and ravines. From a distance the country has the appearance of a vast forest, such is the number of trees planted in the hedge-rows that inclose each field. The population of Lower Maine does not, as is the case in most parts of France, live in hamlets or villages, but is scattered among isolated farmhouses, each of which stands among thick hedges, and contains a family that is supplied with every necessary of life, both of food and clothing, from the land and their own industry. This isolated and independent existence has left its impress on the people in a certain rudeness of address, an honest but obstinate adherence to old usages, and a consequent aversion to things called improvements. The soil in the arrondissement of Château-Gontier, and in part of that of Laval, is productive in bread-stuffs of all kinds; and sufficient corn for home consumption is raised. Meadow land is scanty, nevertheless a great number of beasts are fed, which form a source of considerable profit to the farmer. Flax, hemp, and fruit trees are extensively grown, and the vine is cultivated to a small extent, but the wine made is of inferior quality. Cider and perry are extensively made. The forests furnish timber for the navy. Well-woolled sheep, pigs, and fowls are numerous. Bees are kept in great numbers.

Rivers.—The department belongs almost entirely to the basin of the Loire, and is drained chiefly by the *Mayenne* (the ancient *Meduana*), which rises in the west of the department of Orne, and running nearly south past the towns of Mayenne, Laval, and Château-Gontier, divides the department of Mayenne into two pretty equal parts. It afterwards flows through MAINE-ET-LOIRE, and joins the Loiret on the right, near Angers. The total length of its course is 100 miles, for the last 45 of which it is navigable.

The department is traversed by the railway from Paris to Brest, which passes through Laval.

Industry.—Iron mines are worked for the supply of some smelting furnaces and forges. There are coal mines near Laval. Marble, granite, flint, building and lime stone, and slate, are quarried. White sand, used in the manufacture of glass, is raised. Linen spinning and weaving are the chief manufactures; cotton stuffs, haircloth, linen thread, and paper are made.

The climate is healthy, and resembles that of the south of England.

Divisions, Chief Towns, &c.—The department contains 1,272,312 acres, and is divided into three arrondissements, which with their subdivisions and population are as follows:—

Arronds.	Cantons.	Communes.	Pop.in1861.
Laval, . . .	9	90	133,770
Mayenne, . .	12	110	163,734
Château-Gontier	6	72	77,659
Total, . . .	27	272	375,163

In the arrondissement of Laval, the chief town is LAVAL, which is also the capital of the department. *Argentré*, 6 miles E. from Laval, stands on the slope of a hill near the Jouanne, and has marble quarries, tanyards, and 1745 inhabitants. *Chailland*, 12 miles from Laval, has coal mines, iron forges, smelting furnaces, and a population of 2544. *Evron* stands in a remote but fertile district, 17 miles E. by N. of Laval, and has a population of 5101. This town has a corn market, linen manufactures, and some trade in wine, wool, and brandy.

In the arrondissement of Mayenne, the chief town, *Mayenne*, stands on the steep slopes of two hills, united by a bridge across the river Mayenne, 18 miles N. by E. from Laval, and has a tribunal of commerce, a college, a council of prud'hommes, and 10,370 inhabitants. The streets are irregularly built, and very steep. In the vicinity are some iron foundries. Linen, calicoes, and cotton yarn are the chief industrial products of the town, which has also bleach-mills and dyehouses. *Ambrières*, 6 miles N. from Mayenne, is a well built town of 2720 inhabitants. A castle now in ruins, built here by the Conqueror, is the most interesting object in the town. *Bais*, a town of 2239 inhabitants, S.E. of Mayenne, was burned by the Vendeans in 1799. *Ernée*, prettily situated on the river Ernée, 14 miles W. from Mayenne, is a well built town, with wide straight streets and 6320 inhabitants, who manufacture linen yarn, needles, and cloth. There are iron mines and iron forges near Ernée. The town has a communal college. *Gorron*, 12 miles N.W. from Mayenne, has a population of 2687. The ancient castle of Gorron, one of the frontier fortresses of Maine, has been entirely destroyed, and a corn market erected on its site. *Lassay*, 10 miles N.E. from Mayenne, has 2504 inhabitants and an ancient castle, the erection of which dates from the year 825, and which was the best preserved of the old fortresses of Maine. *Prez-en-Pail*, 20 miles N.E. from Mayenne, on the road to Alençon, has a population of 3300, and a large market for cattle. *Villaines-la-Juhel*, E. of Mayenne, has 2615 inhabitants, who manufacture woollen cloth.

In the arrondissement of Château-Gontier, the chief town, *Château-Gontier*, is situated in a beautiful plain, 16 miles S. from Laval, on the left bank of the Mayenne, over which a stone bridge leads to a large suburb. Of the castle built here by Foulques Nera, count of Anjou, who intrusted its safe keeping to a knight named Gontier (whence the name), there is scarcely a vestige. The town has some bleaching grounds; 7755 inhabitants, who manufacture linen and woollen fabrics, and trade in clover seed, thread, iron, timber, and wine. *Cosse-le-Vivien*, a market town, N.W. of Château-Gontier, has 3372 inhabitants. *Craon*, formerly a fortified town, and famous for its siege by the prince of Conti in 1592, is situated on the left bank of the Oudon, 12 miles W. from Château-Gontier, and has 4291 inhabitants, who manufacture coarse woollens, and trade in corn, linen, thread, &c.

The department forms the see of the bishop of Laval; it is included in the jurisdiction of the Cour Impériale of Angers, and Academy of Rennes; and belongs to the fifth corps d'armée (Tours), and sixteenth Military Division, of which Rennes is head-

quarters. It returns three deputies to the Corps Legislatif.

(*Dictionnaire de la France; Annuaire pour l'An 1866.*)

MAYER, SIMONE, was born in Bavaria, June 14, 1763, and at an early age sent to study music in Italy, in which country he passed the greater portion of his life, and drew his last breath. In 1802 he was chosen maestro di capella to the church of Maria Maggiore in Bergamo. In 1799 appeared his first distinguished opera, now known under the title of 'Il Fanatico per la Musica.' In 1802 he produced his 'Il Misteri Eleusini;' and following on this came his 'L'Equivoco,' 'La Ginevra di Scozia,' 'Lodoiska,' 'Aleramo ed Adelasia,' 'La Rosa Bianca e la Rosa Rossa,' and the most celebrated of all, 'Medea,' in which Madame Pasta made so great an impression throughout Europe. Mayer died in 1845.

MAYER, TOBIAS, was born at Marbach, a town of Wurtemberg, on the 17th of February, 1723. He was left an orphan and unprovided for at a very early age. To gain a livelihood he began teaching the mathematics, and at the age of twenty he studied the principles of gunnery, probably with a view of entering the army. He published a memoir in 1750, 'On the Libration of the Moon.' In 1751 he became director of the observatory at Göttingen, and at the same time or subsequently was appointed professor of economy in that university. At Göttingen, during the remainder of a very short life, he laboured with the most praiseworthy zeal to promote the sciences of geography, navigation, and astronomy. His 'Zodiacal Catalogue' was 'deserving of all confidence' (Delambre), and comprised 998 stars, including those whose correct positions are of most importance to the astronomer. In 1755 he published his 'Lunar Tables' in the 'Acts of the Academy of Göttingen,' and a copy of them was forwarded to the London Board of Longitude. By order of the Board the accuracy of the tables was rigorously tested by Dr. Bradley, who was able in no instance to detect an error greater than 1' 30" (the errors of the other tables then existing sometimes amounted to 10'), and even part of this he was of opinion might be fairly attributed to his own observations. These tables were printed by the Board of Longitude in the year 1767, and likewise the 'Solar Tables' by the same author, in the year 1770. After the death of Mayer at Göttingen on the 20th of February, 1762, the British Parliament, at the recommendation of the Board, paid his widow 3000*l*.

MAYNE, JASPER, was born in 1604, in Devonshire. After being at Westminster school, he was entered as a servitor of Christchurch, Oxford; and in 1631 he commenced M.A. Taking holy orders, he became a popular preacher. He was created D.D. in 1646. Firmly devoted to the royal cause, he was deprived of his student's place in 1648, and two livings which he then held. He resided, till the Restoration, as chaplain in the family of the earl of Devonshire. In 1660 he was restored to his livings; became chaplain in ordinary to the king, a canon of Christchurch, and archdeacon of Chichester. He died in Oxford in 1672. He is remembered only through his plays: 'The City Match,' a Comedy, given in Dodsley's 'Old Plays;' and 'The Amorous Warre,' a tragi-comedy.

MAYNOOTH. [KILDARE.]

MAYO, a maritime county of the province of Connaught, in Ireland, is bounded E. by Sligo and Roscommon, S. by Galway, and W. and N. by the Atlantic Ocean. It lies between 53° 27' and 54° 19' N. lat., and between 8° 31' and 9° 20' W. long. Its greatest length E. to W. is 72 miles; its greatest breadth N. to S. is 58 miles. The area is 2131 square miles, or 1,363,882 acres, of which 497,587 are arable, 800,111 uncultivated, 8360 in plantations, 848 in towns and villages, and 56,976 under water. The population in 1851 was 274,830, and in 1861, 254,796, of whom 246,583 were Roman Catholics, and 6739 belonged to the Established Church.

The coast line, 250 miles in length, is indented with the Bays of Killala, Broadhaven, and Blacksod (the two last being separated from each other by the narrow isthmus of Belmullet), the entrance into the peninsula of the Mullet, Tulloghane Bay, Clew Bay (studded with numerous islets), and the Killerries. Near the coast are the islands of Achill, 35,283 acres; Clare, 3959 acres; Inishturk, 1451 acres; Innisboffin, 2315 acres, and numerous smaller. The surface is of every character; much mountain and waste, and much level and fertile land. The summits of Mulrea, Nephin, and Croagh Patrick are 2680, 2530, and 2370 feet above high sea level; on the summit of the last is a chapel dedicated to St. Patrick.

The soil is mostly light, and with the moist climate better suited to grazing than tillage. The subsoil in the level parts is limestone; in the others red sandstone, mica slate, granite, and quartz; iron ore abounds, but remains unwrought for want of fuel; there are several valuable slate and marble quarries. Lakes Conn, Carragh, Cullen, Castlebar, Carramore Fyogh, and some smaller ones, are within the county; those of Mask and Corrib border it on the south. The occupations are agriculture and fishing; pasturage is more attended to than tillage; the linen manufacture formerly flourished here, but has declined. The salmon fishery on the Moy and the other rivers of the county is very considerable. The breeds of cattle and sheep are generally improved. The chief crops are oats, flax, and potatoes.

The only navigable river in the county is the Moy, which is one of the finest rivers of Ireland. There are no canals. Many good roads have been constructed during the present century.

The coast fishery gives employment to several thousand fishermen. Turbot, sole, cod, ling, hake, haddock, plaice, oysters, lobsters, and herrings are caught.

Divisions and Towns.—Mayo is divided into nine baronies, and contains seventy-three parishes. It is in the diocese of Tuam, Killala, and Achonry; in the Connaught Circuit, and the assizes are held at Castlebar. The county returns two members to Parliament, the number of voters on the register in 1865 being 3679. Mayo is within the Dublin or Northern Military District; and there are barrack stations at Castlebar, Ballinrobe, Westport, Foxford, and Ballaghaderreen.

The following are the principal towns, with the population of each in 1861:—

Ballina is a town and port, 18 miles N.N.E. from

Castlebar, on the banks of the Moy, which here separates the counties of Sligo and Mayo. The river affords excellent salmon fishing, and is the resort of many anglers during the summer season. The population of Ballina proper is 4399; of the portion of the town in the county of Sligo, which is called Ardnaree, 1020: total, 5419 (comprising 4734 Roman Catholics), being an increase of nearly 200 since 1851, contrary to the general rule in Ireland. The town has been much improved of late years, and its trade has greatly increased. It is the seat of a poor-law union, with a large workhouse, and has breweries, flour mills, and manufactures of snuff. The public buildings comprise a fine old church, a large Roman Catholic chapel, Baptist and Methodist chapels, a sessions-house, and two branch banks. Since 1855 Ballina has been governed by a board of fifteen commissioners elected under the Towns Improvement Act (Ireland). The number of vessels which entered the port in 1865 was 101 (9243 tons), and the clearances, 105 (9308 tons). The customs revenue in the same year was 3094*l*.

Ballinrobe is on the Robe, a stream which falls into Lough Mask, 3 miles W. from the town. It contains a sessions-house, union workhouse, church, and Roman Catholic chapel. Population, 2506.

Castlebar, the county town, is situated near the bottom or north-eastern end of the Castlebar Lake, and is watered by the Castlebar River, which flows N.E. and N. to Lough Cullin and Lough Conn. The streets are tolerably regular, and in the square are the county courts, public offices, and a promenade. The town contains also a parish church, spacious Roman Catholic chapel, Methodist meeting-house, castle, infantry barracks, linen hall, workhouse, and county gaol. Castlebar has a good retail trade, and much corn and agricultural produce, and a considerable quantity of coarse linens are disposed of at the weekly markets. It was formerly a parliamentary and municipal borough, but has been disfranchised; and its lighting, paving, &c., is now regulated by twelve town commissioners. Population, 3022.

Clare is a small town with an active retail trade, about 30 miles S. by E. from Ballina, and 13 N.W. from Ballinrobe. Population, 1323.

Crossmolina is a small market town, about a mile from the north-western shore of Lough Conn, watered by the river Deel, which falls into Lough Conn. It consists principally of low slated houses. Population, 1110.

Killala. [KILLALA.]

Westport is a modern town, with regular streets, which were laid out by the late marquis of Sligo with considerable taste; the town occupies a narrow valley, which is watered by a pretty mountain stream running through the centre of it. Two of the principal streets run parallel with the river; and rows of trees on either side form, so far as they extend, the north and south malls. In these streets are a Roman Catholic chapel, court-house, banks, &c. The other streets branch from the malls, and from the acclivity of the grounds are in many places very steep. A good trade is done in corn and provisions, and the distillery and the brewery add considerably to the trade and home consumption of the place. The port and principal corn stores are separated from the town by the intervening demesne of Lord Sligo, and are

about a mile to the westward, at the S.E. extremity of Clear Bay. It is called *Westport Quay*, and has a fishery and several coastguard stations. The parish church is situated in the beautiful demesne of Lord Sligo. There are, besides, in the town a commodious Roman Catholic chapel, and small Presbyterian and Methodist meeting-houses, a linen hall, market house, barracks, a gaol, and workhouse. The linen trade is thriving. Westport is 10 miles S.W. of Castlebar, is governed by eighteen commissioners, and has 3819 inhabitants, 3482 of whom are Roman Catholics. The customs revenue received at the port in 1865 was 1401*l*. The number of vessels which entered the port in the same year was 75 (8372 tons), and the clearances 88 (10,616 tons).

History and Antiquities.—This county formed part of the grant made by King Henry II. to William Fitz-Adelm de Burgh about the year 1180, O'Connor being at that time the native king of Connaught, which included Mayo. There is very little known of the subsequent proceedings of the settlers until the period of the great rebellion succeeding the assassination of William de Burgh, earl of Ulster, in 1333. About this time Mayo was a county. It renounced, however, all subjection to the English law immediately after the murder of the earl, and remained independent for more than two centuries. The first step towards a return to English law and manners was made in 1575, when the chiefs made their submission to Queen Elizabeth; but it was not till 1586 that the English supremacy was fully acknowledged. The old families of Mayo, in general, took part in the rebellion of 1641 and the succeeding wars, and very extensive forfeitures were the consequence. The chief political event after that time was the invasion by the French, under General Humbert, in 1798. The invading force consisted of 1100 rank and file only; but such was the alarm caused by their unexpected descent, that they easily carried the towns of Killala and Ballina; and being joined by a large body of the peasantry, defeated General Lake, at the head of 6000 men, before the town of Castlebar. The surrender of the invading force at Ballinamuck, however, soon restored tranquillity.

The antiquities of the county are chiefly ecclesiastical. There are round towers at Killala, Turlogh, Meelick, and Balla. At Cong are the remains of a splendid abbey, originally founded in the seventh century, and re-edified by O'Connor in the twelfth. At Ballyhaunis are the ruins of a largely endowed abbey, founded by the family of Nangle. Very fine remains of a Franciscan friary at Moyne, founded by William de Burgh, are still standing. Rosserk Abbey, in the same neighbourhood, built by the Joyces in the fifteenth century, is another very striking ruin. The remains of Ballintubber Abbey, seven miles from Ballinrobe, are among the most elegant specimens of early architecture in Ireland. Numerous other remains of religious houses founded by the families of De Burgh, O'Malley, and Nangle, throughout the county, are enumerated.

The military antiquities are not in general of much extent or interest. Carrig-a-Nile, Doona Castle, Inver Castle, and Doonbriste Castle, are the principal.

MAYOR. [MUNICIPAL CORPORATIONS.]

MAZAGAN. [MOROCCO.]

MAZANDERAN. [PERSIA.]

MAZARIN, GIULIO, was born at Pescara in the Abruzzi, on the 14th of July, 1602. His early education was conducted at Rome under the direction of the Jesuits, at whose college he highly distinguished himself; but having attracted the notice of Jerome Colonna, afterwards Cardinal Colonna, he was introduced into the Spanish university of Alcalá, where he continued his studies with great distinction. Returning home, he entered the Pontifical army, serving in the Valteline as captain of infantry; but it was speedily discovered that his genius lay in a different direction. Employed to negotiate between the French and Spanish generals, he was successful in gaining the confidence of both, and in eventually bringing about the peace of Monçon, in 1626. Soon after, France, Germany, Spain, and Savoy being involved in the disputed succession to the duchy of Mantua, and Cardinal Sacchetti being empowered by Pope Urban to act as mediator, Mazarin accompanied him for the purpose of affording assistance. In reality the prime mover of the affair, every success crowned his efforts, when, in 1631, he effected the treaty of Cherasco, which restored and established peace. In 1634 Mazarin was despatched as nuncio to Paris, where, if he did not obtain the object of his mission, he at least contrived to ingratiate himself with the French monarch. In 1636, therefore, he returned to Rome as the agent and champion of the court of France; but Urban declined to gratify Louis by making his envoy a cardinal, and in 1639 the latter again left Rome for Paris. Having been appointed ambassador to Savoy, where his exertions restored peace, we find, in 1641, the name of Mazarin in the list of promotions to the conclave. During the famous Cinq-Mars conspiracy, the new cardinal remained a faithful adherent of his illustrious patron, Richelieu, and on the decease of the latter in 1642, immediately entered upon the functions, if he did not bear the title, of prime minister. The queen-regent, Anne of Austria, however, being prejudiced against Mazarin, raised the bishop of Beauvais to the post of premier; but the sagacious Italian was not slow in convincing her of her mistake, and quickly regained the reins of power. During the long minority of Louis XIV., Mazarin continued to administer the regency; and under his rule the foreign policy of France was completely successful, although at home the country was the prey of intestine strife. Carrying out the projects of his predecessor, Mazarin continued the war with Spain and Germany—a war immortalized by the heroic memories that cluster round such names as those of Condé and Turenne. Finally, the French minister had the satisfaction of concluding the peace of Westphalia, by which the European strife of thirty years was closed, France also gaining thereby several important territorial acquisitions. Meanwhile, the war of the Fronde tormented the vitals of the kingdom; it had broken out the very same year that the war with Germany was concluded; and the Parliament of Paris, in conjunction with the higher aristocracy, revolted against the authority of Mazarin. Headed by the cardinal de Retz, the Frondeurs simply declared against the minister, simultaneously asserting their attachment to the throne. At the outset, Mazarin was forced to yield and flee the capital at the peril of his life; but by dint of subtle plotting

and machinations, he counteracted the efforts of his foes; the disorders of the Fronde were conclusively terminated by the declaration of the king's majority in 1653, and the cardinal was restored to the full enjoyment of unbounded power. But at the comparatively early age of fifty-nine, Mazarin expired at Vincennes on the 9th of March, 1661, meeting death with unshrinking firmness. It has been observed by a recent writer, that of the remarkable ability displayed by Mazarin there cannot be a doubt. Attempts have indeed been made at different times and by various individuals to undervalue his reputation; but that he divined the character of Louis XIV., that he trained Colbert, that he detected and overcame De Retz, may well be received as infallible proofs of his penetration, his skill, and his political sagacity. Inferior in gigantic grasp of mind to Richelieu, he possessed a manœuvring and diplomatic genius that was emphatically his own. Constitutionally timid, he was no hero; he had no great inborn ideal of statesmanship to guide him in his path, and his chief glory was that he walked, an apt pupil, in the footsteps of his great master.

MAZEPPA, IVAN STEPHANOVITCH, Hetman (that is, commander-in-chief) of the Cossacks of the Ukraine, has become celebrated by a poem of Lord Byron, which has for its subject his extraordinary adventure. He was the son of a Polish gentleman in Podolia. The popular story of his arrival among the Cossacks on the back of a wild horse to which he had been bound by the husband of a woman whom he had seduced, has been superseded by a prose version given in the contemporary memoirs of Passek, which state that he retired among the Cossacks overwhelmed with shame at his exposure in his native land. He was born about 1640 in Podolia, was educated at court, and became page to John Casimir, king of Poland. His military talent as displayed at the head of the Cossacks obtained for him the title of Hetman. His submission to the czar of Muscovy, and his secret league with Charles XII. of Sweden, are matters of history. He died in Turkey, whither he had retreated after the battle of Poltava, about 1709.

MAZÈRES-EN-AOIX. [ARIÈGE.]

MAZZOLINI, LODOVICO, a painter of Ferrara, sometimes called Lodovico Ferrarese, was born about 1481. His works are miniature altar-pieces, and are on the whole little inferior to the small works by Garofalo. He died at Ferrara in 1530. His masterpiece is considered to be the picture on wood of 'Christ disputing with the Doctors', in the Gallery of Berlin. There are also three very characteristic works of this master in the National Gallery in London.

MAZZUOLI. [PARMIGIANO.]

MEACO. [MIACO.]

MEAD, a beverage made of water and honey by fermentation. It has been in use from ancient times, and is mentioned by Pliny, who says it has all the bad qualities of wine and none of the good ones. It is, however, a very luscious and palatable liquor.

MEAD, RICHARD, M.D., was born at Stepney, 11th August, 1673. He took the degree of M.D. at Padua in 1695. On his return to England he was appointed physician to St. Thomas' Hospital, London, in 1703; anatomical lecturer at Surgeons'

Hall in 1711; and was afterwards elected a fellow of the Royal College of Physicians. He was also physician to George II. His reputation was very great. He died in 1754. Dr. Mead published 'A Mechanical Account of Poisons,' London, 1702; 'A Short Discourse concerning Pestilential Contagion,' 1720; some papers on Grecian coins struck in honour of physicians; 'On the Scurvy,' 1749; 'On Small Pox and Measles,' 1748; 'Medicina Sacra, seu de Morbis Insignioribus qui in Bibliis memorantur,' 1748; 'Monita et Præcepta Medica,' 1751.

MEADOW SAFFRON. [*Colchicum autumnale*.]

MEADOWS are properly low grounds on the banks of rivers, which, being kept moist by their situation, and also occasionally flooded by the rise of the waters, are best adapted for the growth of grass, and are generally mown for hay. Some meadows of great extent, belonging to a community or district, in which every inhabitant has a right to send his cattle to graze under certain regulations, are never mown.

When meadows are private property they become much more valuable. The flooding is encouraged or prevented according to circumstances, and in many cases artificial irrigation is adopted. [IRIGATION.] If they are exposed to be too often inundated, they are protected by dams and sluices.

The herbage of low wet meadows is generally coarser and less nutritious than that of those which lie higher: hence upland hay, as it is called, is preferred for the better sort of cattle. Upland meadows are very valuable wherever there is a demand for good hay. Not being annually recruited by flooding, they would degenerate if some pains were not taken to keep up their natural fertility. This may be done in various ways: the most obvious is to recruit them frequently with the richest animal and vegetable manure, which, being spread over the surface at a time when showers are abundant, that is, either early in spring or immediately after midsummer, is washed down to the roots of the grass. A meadow, the soil of which is naturally of a rich nature, and adapted to produce fine grasses, may be mown year after year without any perceptible change in the quality of the hay; but meadows of inferior quality require to be occasionally cropped close, to check the growth of the coarser grasses, and to allow the finer to rise.

Of late years the practice of *soiling* has been extensively adopted; that is, all the grass is mown and carried every day in a green state, to cows or horses tied up in a stable. By this means all the advantage of mowing for hay is obtained, besides an abundant supply of rich manure, which can be applied to the land in a liquid and diluted state, when its effect is powerful and certain.

When a natural meadow has been neglected, and the grass is of an inferior quality, and mixed with rank weeds and moss, it requires much care to restore it to its original fertility. In most cases the shortest method and the best is to plough it up, clean and manure it during a course of tillage, and then to lay it down again in a clean and enriched state, by sowing the best sort of grass seeds.

It must be observed that it is not a matter of

indifference what cattle are turned into the meadow after hay-making. Horses invariably produce coarse weeds by their dung and urine; cows may be depastured in autumn, as long as the surface is dry; but sheep are far more advantageous, and may be kept in the meadows at all times, if they are not too wet for the health of the sheep, and if there is no danger of their having the rot. As soon as the surface becomes soft by the autumnal rains, cattle should be excluded.

MEAL-WORM (*Tenebrio molitor*), the name of a heteromorous beetle whose larva occurs in meal; thus the name.

MEAN. By the mean of two or more quantities is meant an intermediate quantity determined by mathematical rules. There are more ways than one of finding a mean, but the two principal results of this kind are called the *arithmetical mean* and the *geometrical mean*. The names are not properly expressive of the distinction between them, but they are established by use.

An arithmetical mean is the simple *average*, formed by adding the quantities together, and dividing by the number of quantities. A geometrical mean is the square root of the product of the quantities.

The arithmetical mean, or average (which is always to be understood when the word mean is mentioned, unless the contrary be specified), is taken to be the most probable result of a number of discordant quantities, which would have been the same but for errors of observation or experiment.

In assuming the average as the most probable result, it is presumed that any one measurement is as likely to err one way as the other; that is, as likely to be too small as too great. If nothing but results be known, this presumption is justifiable; but if it be known that there is more tendency to error of one sort than the other, the most probable result cannot be ascertained until it is found out by how much the average of a very large number of observations would be affected by this tendency.

It is obvious that when observations nearly agree with each other, the average must be nearly the truth required, and the nearer the agreement of the observations, the more nearly. If the observations do not agree well, the average is still more likely than anything else, but not so likely as before.

MEARNS. [*Kincardineshire*.]

MEASLES (*Morbilli*, *Rubeola*), is the popular name of a contagious disease, characterized by an eruption on the skin, chiefly affecting children, and seldom attacking the same individual more than once.

It is ushered in by more or less fever, a running from the nostrils and eyes, with some inflammation of the latter, sneezing, hoarseness, a dry cough, difficulty of respiration, and occasionally slight soreness of the throat. The rash usually appears on the fourth, but sometimes on the third, fifth, or sixth day of a febrile disorder; and after a continuance of four days, gradually declines with the fever. The eruption first shows itself in distinct red and nearly circular spots, having some resemblance to flea-bites: these spots gradually coalesce and form small slightly elevated patches of an irregular figure, but approaching nearest to that of semicircles or crescents. At the commencement of the eruption

the catarrhal symptoms and fever are somewhat augmented, and during its height the whole face is often swollen and the eyelids thereby closed; on its decline, which begins on the fourth or fifth day, the fever ceases, and from those parts of the body previously covered by eruption the cuticle separates in small bran-like scales. With respect to the treatment, little is required during the eruptive stage of the disorder, which is seldom attended with danger. It is chiefly necessary to open the bowels, to confine the patient to a light vegetable diet, with cold acidulated aqueous drinks, and to maintain a cool temperature in the room, which should be moderately darkened. It is frequently epidemic in this country, and although sometimes assuming a fatal type, it is more frequently mild.

MEASURE. One number or magnitude is said to measure another, when the first is contained an exact number of times in the second. [INCOMMENSURABLES; PROPORTION.]

MEASURES. [WEIGHTS AND MEASURES.]

MEAT. In the boiling of meat some regard should be paid to scientific principles. In the general cookery of domestic life this knowledge is most essential. Liebig, the celebrated German chemist, has devoted much attention to the subject; and he has lately published a work on the 'Chemistry of Human Food.' He there tells us that the slow boiling of flesh effects a chemical change in its composition; and that, according to the length of time employed in boiling and the amount of water used, a more or less perfect separation of the soluble from the insoluble constituents takes place. The water or soup in which the flesh has been boiled contains the soluble matter, and the *bouilli*, or meat from which the soup was made, consists chiefly of fibrous, insoluble matter, nearly useless as nourishing food. Thus it is obvious, that when the water in which the meat has been boiled slowly is thrown away, by far the greater part of the soluble or nutritious matter is wasted.

A very different mode of cooking should be adopted when it is wished to eat the meat. The muscular fibres of flesh in its natural state are everywhere surrounded by a liquid containing dissolved albumen. When this is removed by boiling with water, the muscular fibre becomes hard and bony, and this hardness increases the longer it is boiled. 'It is obvious, therefore,' observes Liebig, 'that the tenderness of boiled meat depends upon the quantity of albumen deposited between the fibres, and there coagulating: for the contraction or hardening of the fibres is thereby, to a certain extent, prevented. If the flesh intended to be eaten be introduced into the boiler when the water is in a state of brisk ebullition, and if the boiling be kept up for some minutes, and then so much cold water added as to reduce the temperature of the water to 165° or 158°, the whole being kept at this temperature for some hours, all the conditions are united which give to the flesh the qualities adapted to its use as food. When it is introduced into the boiling water, the albumen immediately coagulates from the surface inwards, and in this state forms a crust or shell; which no longer permits the external water to penetrate into the interior of the mass of flesh. But the temperature is gradually transmitted to the interior, and there effects the conversion of the raw flesh into the state of boiled

meat. The flesh retains its juiciness, and is quite as agreeable to the taste as it can be made by roasting.

MEATH, formerly distinguished as *East Meath*, a county in the province of Leinster, in Ireland, is bounded N. by Monaghan, N.E. by Louth, E. by the Irish Sea, S.E. by Dublin, S. by Kildare, S.W. by King's County, W. by Westmeath, and N.W. by Cavan. Its form is very irregular. Its greatest length E. to W. is 47 miles; its greatest breadth N. to S. is 40 miles. The area is 906 square miles, or 579,899 acres, of which 547,391 are arable, 16,033 uncultivated, 12,767 in plantations, 464 in towns and villages, and 3244 under water. The population in 1851 was 140,750; in 1861, 110,373, comprising 103,327 Roman Catholics, and 6492 members of the Establishment.

Surface, Coast Line, Geological Character.—The coast has a tolerably straight outline running south by east from the mouth of the Boyne to the boundary of the county of Dublin near Gormanstown. The shore is low, skirted by sand-banks or hills, and broken by one or two small streams which flow into the sea. The county has altogether only about ten miles of coast, and no harbour of importance. The climate is comparatively dry and cold. The surface is mostly level or undulating, rising towards the west and north-west.

The county of Meath is for the most part included in the great central carboniferous limestone district of Ireland; the whole of the southern part of the county, and considerable portions of the north and west, are occupied by this formation. A small tract is occupied by the rocks of the limestone formation, and by a small coal-field, the beds of which, however, are found to be not worth working.

The county belongs almost entirely to the basin of the Boyne; a small portion in the northern part belongs to that of the Dee, the heights about Slane separating the two. The southern and south-eastern borders are watered by the affluents of the Liffey, or by some smaller streams which flow into the sea between the Liffey and the Boyne. The chief affluents of the Boyne are the Blackwater, Menagh, Blind, and Deel. The Boyne flows into the sea near Drogheda. The Nobbor is the chief tributary of the Dee. There are several small lakes. Lough Sheelin, which separates the counties of Meath and Westmeath from that of Cavan, is of an oval form, 5 miles long, and about 2½ miles broad. It contains a small islet called Church Island, with the ruins of an old church on it. Lough Bawn, 1½ mile long, but very narrow, and some smaller lakes, lie on the western border of the county. The lake of Kilminalham, formed by an expansion of the river Nobbor, is about one mile long and above a quarter of a mile broad. Bogs are numerous, but the aggregate of their extent is small: the largest is on the border of the county south-west of Athboy.

About 14 miles of the Royal Canal pass through this county, giving access to Dublin and to the Shannon. The county is tolerably well provided with roads, and it is traversed by the Dublin and Drogheda and the Midland Great Western Railways.

Agriculture and Productions.—This county has very few mountain wastes. The land is level, and rich pasturage. The soil is for the most part a loam of the richest character, and in many places of such

depth that the turning up of a fresh portion of the soil by ploughing deeper than usual is considered as an efficient substitute for manuring. The whole quantity of land devoted to green crops is small, in consequence of the abundance of the natural pastures, which are of unequalled richness, and have led the farmers to give their chief attention to grazing.

The quantity of cattle fattened in the pastures of the county is considerable, and the breeds are of superior kinds. The grazing is carried on on a large scale. Many persons fatten from 300 to 500 cows in a season, besides bullocks and sheep. The horses are generally of an inferior kind. The pigs are of a good breed. Poultry is abundant.

The occupations of the inhabitants are almost exclusively agricultural, but some coarse linens are manufactured.

Divisions and Towns.—Meath is divided into eighteen baronies, and contains 146 parishes. It is in the diocese of Meath, which was founded about 1150. Portions of the county are in the dioceses of Armagh and Kilmore. It is in the Home Circuit, and the assizes are held at Trim. The county returns two members to Parliament, the number of registered electors in 1865 being 4155. Meath is within the Dublin or Northern Military District; and there are barrack stations at Navan and Trim.

The following are the principal towns, with the population of each in 1861:—

Athboy, 'the Yellow Ford,' a small town, 7 miles N.W. from Trim, is watered by a stream called the Athboy River, a feeder of the Boyne. Population, 982.

Drogheda is partly in Meath. [DROGHEDA.]

Kells, a very ancient market town, is 10 miles N.W. from Navan, near the south bank of the Blackwater, and on the Kells extension of the Navan branch railway, 36 miles N.W. from Dublin. It contains a sessions-house, a handsome Roman Catholic chapel, an ancient church, with a round tower and cross in the churchyard, and an ancient stone cross, richly carved, in the centre of the town. There are also a district bridewell, union workhouse, fever hospital, market-house, two banks, and some manufactures of lace. The town is governed by fourteen commissioners, who regulate the paving, lighting, cleansing, draining, water supply, &c. The principal proprietor is the marquis of Headfort, whose seat is in the immediate neighbourhood. There is something very imposing about the entrance to Kells—the spacious and well-wooded avenues, the wide streets, adorned with old trees, and terminated by the venerable church and handsome Roman Catholic chapel. The town is improving; and at the weekly markets considerable quantities of produce are disposed of. Population, 3224.

Navan, a market town, is situated at the confluence of the Blackwater with the Boyne, 26 miles N.W. from Dublin, with which, and with Drogheda, it is connected by railway. The town consists of three main streets, from which several lanes branch off. It contains a handsome church and a spacious Roman Catholic chapel, a court-house, a barrack, infirmary, fever hospital, two banks, and a union workhouse. The town is situated in a very rich agricultural district, and much corn is sold at the weekly markets. Brewing, distilling, flax-spinning,

and paper-making, are carried on, and there is a large retail trade. The town has also numerous corn mills, some manufactures of sacking, and exports considerable quantities of agricultural produce by the Boyne. Fifteen town commissioners regulate the local affairs of Navan. Population, 4187, including 4002 Roman Catholics.

Trim, the county town of Meath, 25 miles N.W. from Dublin, is situated on the banks of the Boyne, over which there is an old bridge. It is a very ancient place. The remains of a castle, built in 1220, occupy an area of four acres, and consist of the keep and various other towers and outworks. There are also some remains of an abbey, and a tower of great antiquity is connected with the parish church. The county court-house is a modern structure, and there is a new county prison, a spacious building. Trim is not a place of much thoroughfare, and has little trade. It is a disfranchised parliamentary borough, and is now governed by twelve town commissioners. Besides the parish church there is a Roman Catholic chapel, schools, infantry barracks, union workhouse, bank, &c., and a pillar to the late duke of Wellington, who is said to have been born at the demesne of Dangan, 3 miles S. of the town. This place was taken by Cromwell in 1649. Several Irish parliaments have been held here. Population, 2058, of whom 1791 are Roman Catholics.

History and Antiquities.—At an early period Meath constituted one of the kingdoms into which Ireland was divided. Teamor, now Tara Hill, near the Boyne, was the residence of the sovereign of Ireland, and the seat of the supreme government, and the place where St. Patrick made his first efforts for the conversion of the Irish to Christianity. The kings of Meath became afterwards tributaries to the kings of Ireland. In the invasions of the Northmen, or Danes, the kingdom of Meath suffered severely. Before the invasion of Ireland by Henry II., Dermot MacMurchad, king of Leinster, had reduced O'Melaghlin, king of Meath, and other princes, into a state of subjection; but a quarrel between some of these chiefs led to an invitation by one of them to the English to enter Ireland; and the result was that Richard Strongbow took possession of Meath in 1171, which was conferred by Henry II. as a county palatine on Hugh de Lacy, who was appointed governor of the English pale or district.

For a century and a half Meath was a scene of conflict, sometimes between the English and the Irish, and sometimes between the king and the powerful barons. The English dominion, never fully established, appears rather to have decayed during the reigns of the latter Plantagenet and the Lancastrian princes, and the civil war of the Roses. In the reign of Henry VIII. the power of the English began to revive, when the ancient county of Meath was divided, and West Meath, including the present counties of West Meath, Longford, and part of King's County, was formed into a separate county.

There are several remains of antiquity in the county. At Tara, once the seat of the Irish monarchs, are considerable earthworks. There are considerable ruins of the castles of Scurlogstown, Dunmoe, Athlumley, and Asigh. Slane Castle and one or two others have been fitted up as residences. There are

round towers at Kells, and at Donoughmore, near Navan. There are numerous ruins of ancient monastic edifices: those of the monastery at Duleek, supposed to be the most ancient monastic edifice built of stone and mortar in Ireland, present some remarkable traces of rude architecture. The front of the ancient cathedral at Clonard yet exists, and there are several stone crosses. The ruins of Beective Abbey are extensive and picturesque.

MEATH, WEST, or as it is sometimes written in one word, WESTMEATH, is an inland county of the province of Leinster, in Ireland, bounded by Meath, King's County, Roscommon, and Longford. The greatest length E. to W. is 40 miles; the greatest breadth N. to S. is 35 miles. The area is 708 square miles, or 453,468 acres, of which 365,218 are arable, 56,392 uncultivated, 8803 in plantations, 628 in towns and villages, and 22,427 under water. The population in 1851 was 111,409; in 1861 it had fallen to 90,879, comprising 83,749 Roman Catholics, and 6336 who belonged to the Church of England.

Surface and Geology.—The county is for the most part a gently undulating surface, not rising in any part to a very great height. The whole belongs to the central carboniferous limestone district of Ireland, with the exception of two small districts of yellow sandstone.

The western side of the county belongs immediately to the basin of the Shannon, which forms its western boundary. Lough Ree, the largest of the series of lakes into which that river expands, is also on the western border. This noble sheet of water is 17 miles long from north to south, and of a varying breadth, above 7 miles in one part. Its outline is exceedingly broken and irregular, and its surface studded with a number of small islands finely wooded, some of which have ecclesiastical ruins. The streams which flow into the Shannon or into Lough Ree are all small. There are many small lakes and small bogs.

The central part of the county is drained by streams that empty their waters into several inland lakes, which are connected by small streams with each other, and ultimately with the river Shannon. The chief of these lakes are Lough Sheelin, Owel, Ennel, and Deveragh. These lakes vary from 6 miles to 2 miles in length, and some of them are studded with small islands.

The eastern and south-eastern sides of the county abound with bogs, and some of them are of very considerable extent. The lakes of West Meath abound in pike and very fine trout.

Agriculture and Industry.—The soil comprises heavy loam, light loam, hilly sheep-walks, and a great deal of bog. The chief crops raised by the farmer are oats and potatoes, with some wheat. Flour and meal are manufactured in large quantities. The occupations of the inhabitants are wholly agricultural—chiefly grazing and dairy farming. The long-horned cattle are much valued; some of the best specimens are grazed in this county, and all the stock participate in the blood. The sheep also are of superior breeds.

The Shannon is navigable for steamboats conveying goods and passengers. The Royal Canal crosses this county from east to north-west, and a branch of the

Grand Canal proceeds to Kilbeggan. The principal roads are good. The Midland Great Western Railway passes through the county.

Divisions and Towns.—West Meath is divided into twelve baronies and sixty-three parishes. It is chiefly in the diocese of Meath and the Home Circuit; the assizes are held at Mullingar. The county returns two members to Parliament, and one member is returned for the borough of Athlone. The number of voters on the county register in 1865 was 3568. West Meath is within the Dublin or Northern Military District, and there are barracks at Mullingar.

The following are the principal towns, with the population of each in 1861:—

Athlone is partly in West Meath and partly in Roscommon. [ATHLONE.]

Kilbeggan, 14 miles S.S.W. from Mullingar, is situated on the upper Brosna, and is connected by a branch canal with the Grand Canal, by which corn and other agricultural produce are sent to Dublin. Population, 1283.

Moate, 10 miles E.S.E. from Athlone, contains a neat court-house, a church, Roman Catholic chapel, and meeting-houses for Methodists and Quakers. Population, 1960.

Mullingar, the county town of West Meath, is situated near the centre of the county, and is watered by the Brosna, here a small stream. It is on the Royal Canal (which connects it with Dublin and the Shannon), and is 50 miles W.N.W. from Dublin by the Midland Great Western Railway. It is an important junction railway station. The business is limited to the retail trade of the district, and to the regular cattle fairs and markets. The public buildings of the town comprise the parish church, which is a handsome structure; a large Roman Catholic chapel, considerably enriched in its exterior; a nunnery; two schools; county infirmary; market-house; two banks; extensive infantry barracks and the union workhouse, both at a short distance from the town; and the county gaol and court-house, which are substantial and plain buildings. The local affairs of the town are administered by fifteen commissioners. Population, 5375.

History and Antiquities.—This county was included in the kingdom of Meath, of which it formed the western division. In common with the rest of that kingdom, it suffered severely both from the ravages of the Danes and from civil dissensions, and was included in the county palatine of Meath, granted by Henry II. of England to Hugh de Lacy. It was the scene of frequent hostilities for several centuries between the native Irish and the English. West Meath was separated from Meath or East Meath in the reign of Henry VIII. In most of the subsequent dissensions it shared the fate of the parent county.

There are many vestiges of antiquity scattered through the county, as well as numerous ruins of ancient castles, including some erected by the De Lacys. Sonnagh Castle, one of these, stands on the verge of a small but picturesque lake. Of monastic buildings there are several ruins; and some churches, formerly conventual, are still used for divine worship by Catholics or Protestants.

MEAUX. [SEINE-ET-MARNE.]

MECCA, or MEKKA, the birth-place of Mohammed (571), and the holy city of the Mohammedans,

is situated in that part of Arabia which is called El Hejaz or Hedj, about $21^{\circ} 38'$ N. lat., and $40^{\circ} 8'$ E. long., 70 miles from the Red Sea, in a straight line.

This city is situated in a narrow and sandy valley, bounded by mountains from 200 to 500 feet high. The streets of Mecca are broader than those of eastern cities in general, the houses lofty and of stone, and they have numerous windows which give them a lively and European aspect. The only public place in the body of the town is the large square of the great mosque, which is only enlivened during the Haj (Pilgrimage) by the great number of well-stored shops. The streets are all unpaved, and the town is badly supplied with water—mostly by an aqueduct from the vicinity of Arafat. Most of the houses are constructed for the accommodation of lodgers, and divided into numerous separate apartments, each consisting of a sitting-room and a small kitchen. Except four or five houses belonging to the sheriff, two colleges, and the mosque, Mecca has no public edifices.

The mosque, called Bait-ullah ('God's House'), is only remarkable for the Kaabah ('cube'), which it incloses. The Kaabah stands in an oblong square, surrounded by colonnades; on the east there are four rows of pillars, and on the other sides only three. They are united by pointed arches, every four of which support a small dome, plastered and whitened on the outside. The number of these domes is 152. Seven paved causeways lead from the colonnades towards the Holy House, in the centre—an oblong massive structure, constructed of the gray Mecca stone, in large blocks of different sizes, joined together in a very rough manner. The only door which leads into it is opened only two or three times in the year. At the south-eastern corner of the Kaabah, near the door, is the famous Black Stone. It is an irregular oval, about seven inches in diameter, composed of about a dozen smaller stones of different sizes, well joined together with cement, and perfectly smoothed. Every pilgrim kisses this stone, and it is believed to be the angel who, at the last day, will indicate those of the faithful by whom the Haj has been duly performed. [KAABAH.]

There are several other buildings within the area of the mosque, mostly appropriated to reading prayers, preaching, or the performance of devotions. The Zemzem, or Holy Well, is supposed to be the spring found in the wilderness by Hagar; it is inclosed in a square building of massive construction, and the well-room is beautifully decorated.

The Meccawi, or inhabitants of Mecca, with few exceptions, are Arabians from different countries; but they have amalgamated, and they wear the same sort of dress and have adopted the same customs. They are estimated to number altogether from 30,000 to 60,000. Except a few potteries and dyeing-houses, the people of Mecca have not a single manufacture. During the Haj Mecca becomes one of the largest fairs in the East, and certainly the most interesting, from the variety of nations which frequent it. And from this cause the profligacy of the city, as described by Mr. Palgrave in his recent work on 'Central and Eastern Arabia,' is rampant.

Mecca is governed by a sheriff, chosen from one of the many tribes of sherifs, or descendants of Mohammed, in the Hedjaz.

ME'CHAIN, PIERRE-FRANÇOIS-ANDRÉ, was born 16th August, 1744, at Laon, a town of France, in the present department of Aisne. An accident brought him under the notice and patronage of Lalande. The necessity of affording some pecuniary assistance to his father obliged Mechain to dispose of an astronomical instrument which, by rigid economy, he had recently been able to purchase. Lalande became the purchaser, and, after acquainting himself with the past history of Mechain, procured for him a government appointment as hydrographer. In 1791 the National Convention having determined upon employing the length of the arc of the meridian comprised between Dunkirk and Barcelona as the basis of their new trigonometrical measures, the measurement of the southern portion of this arc, between Rodez and Barcelona, was, at the recommendation of the Academy, confided to Mechain. The northern portion was allotted to M. Delambre. His skill as an observer is particularly mentioned by Delambre, and also the accuracy of all his calculations connected with the survey. Of this Mechain himself was unconscious. He had employed the repeating circle, an instrument which he regarded as absolutely infallible, and finding a difference of three seconds between his observations at Barcelona and Montjouy, he attributed it wholly to his own incapacity. Upon his return to Paris, which he reached with much personal risk, fearing to divulge this discrepancy, he refused to deliver his papers to the Academy. The subject continuing to prey upon his mind, he applied, after several years, to the French Board of Longitude, and urged them to prolong the measurement of the arc from Barcelona to the Balearic islands. To this the Board consented; but being unwilling to dispense with his services at the Paris Observatory, they suggested that Mechain should not be the conductor of the survey. This, however, would have been to relinquish the chief object of his application. He obtained permission to depart, but soon after his arrival in Spain he was attacked by an epidemic disorder, of which he died on the 20th of September, 1805, at Castellon, a town of Catalonia.

MECHANICAL POWERS is the name given to certain simple machines, in which one driving force or effort is made to produce motion against one resistance. As to the general principle of the action of machines, known as that of the 'Conservation of Energy,' or of the 'Equality of Energy and Work,' see the article MACHINE. When only one driving force and one resistance are concerned, that principle leads to the consequence that the effort and the resistance are to each other inversely as the velocities of their points of application, called respectively the driving point and the working point. The use of a machine is to enable an effort, acting through a given distance, to overcome either a resistance greater than the effort through a less distance, or a resistance less than the effort through a greater distance. The theoretical condition of there being but one effort and one resistance is never exactly realized; because in addition to the useful resistance there are always wasteful resistances, which render a greater effort necessary to drive the machine than if the useful resistance alone were to be overcome. In estimating efforts and resistances it is to be borne in mind that an effort acts directly with, and a resistance directly

against, the motion of its point of application; so that when a force is applied to a point in a machine, in a direction oblique to the motion of that point, that force is to be resolved into a transverse component and a direct component, and the direct component alone taken into account. In many writings on the mechanical powers, the resistance is called the 'weight,' and the effort the 'power.' The mechanical powers are classed as follows:—

I. Simple machines, consisting of a body turning about an axis, and having a resistance opposing, and an effort promoting that motion, which forces bear to each other the inverse ratio of their leverages, or perpendicular distances from the axis. This class comprehends the LEVER, and the WHEEL AND AXLE.

II. Simple machines in which the advance of a moving piece is promoted and opposed by a pair of forces, one or both of those forces being oblique to the direction of motion. This class comprehends the WEDGE, the INCLINED PLANE, and the SCREW.

III. Simple machines in which a body is pulled by two or more piles of one cord. This class comprehends the PULLEY.

MECHANICS (from *Μηχανή*, 'machine,' 'device'), originally meant the art of contriving and making machines: then it was extended to the science of the action of machines; and it now comprehends the whole science of those relations of bodies to each other which consist in *motions*, and in tendencies to produce or to prevent motion, called *forces*. The science of mechanics, in its most comprehensive sense, is divided into two branches: *Cinematics*, or *Kinematics* (from *κίνημα*, 'motion'), relating to the comparison of motions with each other; and *Mechanics* proper, to which it has been proposed by some authors to apply the name *DYNAMICS* (from *δύναμις*, 'power,' or 'force'), relating to forces as well as to motions. The latter branch is again subdivided into *STATICS* (*στατική*), relating to balanced combinations of forces, and what is usually called *Dynamics*, and by some authors, *Kinetics* (from *κίνησις*, 'a mover'), relating to forces as causing motion. Another mode of subdivision of mechanics into branches is founded on the condition, solid or fluid, of the bodies whose actions and motions are considered; and is indicated by the prefixes *stereo* (from *στερεός*, 'solid'), and *hydro* (from *ὕδωρ*, 'water'). The prefix *stereo* is used seldom, but *hydro* frequently, as in *HYDROSTATICS*, *HYDRODYNAMICS*, *HYDRAULICS* (the last term meaning properly the science of the flow, or conveyance of fluids, from *αὐλῶν*, 'channel'). *PNEUMATICS* (from *πνεῦμα*, 'wind') means the mechanics of fluids in the gaseous state.

All motions may be expressed by means of changes in the relative distances and directions of points; and all such distances and directions are subjects of geometry; hence all questions in cinematics are solved by geometry. The application of the principles of cinematics to machines constitutes a branch of applied mechanics called *PURE MECHANISM*. [MECHANISM.]

The science of statics is founded on two facts:—*That every force consists in a pair of equal and opposite actions between a pair of bodies*; and *that forces can be represented in direction and magnitude by straight lines*. The former fact is called the *LAW OF ACTION AND REACTION*. The latter fact enables

questions respecting combinations of forces to be solved by geometry: the result of putting together a number of forces being found by putting together the lines representing those forces.

The science usually called *Dynamics*, and by some authors *Kinetics*, is founded on two facts called, the *LAW OF MOTION*. The *FIRST LAW* is, that a *body under no force, or under balanced forces, moves uniformly as to direction and speed*; in other words, *to change the speed or direction of a body's motion requires an unbalanced force*. The *SECOND LAW* is, that *an unbalanced force produces a change in the body's velocity in the direction of that force, which change is proportional directly to the magnitude of the force and the time during which its unbalanced action continues, and inversely to the mass of the body*.

An immediate consequence of the second law is, that an unbalanced force produces a change in the half-square of the velocity with which a body is moving along the line of action of that force, which change is an increase or diminution, according as the force acts with or against that motion, and is proportional directly to the force and the distance through which it acts in its own direction, and inversely to the mass of the body.

The law of action and reaction is sometimes called the 'Third Law of Motion,' but it is in fact a law which holds of all forces, whether producing motion or only tending to do so.

Mechanical Quantities are motions, times, and forces, and quantities depending on motions, times, and forces. The following is a statement of the chief kinds of mechanical quantities, and the principles of their measurement:—

Motion of Translation is simply the length of the line described by a point in the act of changing its position relatively to some other point, and is measured like any other length.

Motion of Rotation consists in the turning of a body into a new angular position, and is measured either in turns and fractions of a turn, or in *circular measure*; that is, by the ratio of a circular arc subtended by the angular motion to the radius of that arc. One turn = 6.2832 nearly, in circular measure. Circular measure is that generally used for scientific purposes.

Time is measured by means of some motion believed to be uniform, or sensibly uniform, such as the rotation of the earth; or by the repetition of equal and similar motions by a given body under precisely similar circumstances, as by the swings of an accurate pendulum.

Velocity, or *Linear Velocity*, is measured by dividing the extent of a motion of translation by the time that it occupies, and is expressed in units of motion per unit of time (as in feet per second).

Angular Velocity is measured by dividing the extent of a motion of rotation by the time that it occupies, and is expressed, for practical purposes, in turns and fractions of a turn per unit of time; and for scientific purposes in circular measure per unit of time.

Acceleration is the rate at which the velocity of a body increases; and *Retardation* the rate at which it diminishes; each found by dividing the change of velocity by the number of seconds that it occupies.

Deviation is the rate at which a body swerves from a straight course, and is found by dividing the square

of the velocity of a body moving in a curve, by the radius of that curve.

Force is measured in two ways, statically and dynamically; and the fact of the agreement of the results of those two ways of measurement is the second law of motion in another shape. The statical measurement of forces is performed by balancing them against each other, either directly or by the aid of suitable machines. It is practicable only with forces exerted amongst bodies at and near the earth's surface, and therefore accessible to man. The unit adopted as a standard in this mode of comparing forces with each other is the weight of some individual body, preserved for the purpose: in Britain, for example, it is the weight of a piece of platinum, called the *standard pound*, kept in the Exchequer Office at Westminster. The dynamical (or as some would call it, the kinetic) measurement of forces is effected by comparing together the motions impressed by them on a given mass of matter in a given time; and this is practicable with bodies whether near or distant, so long as their motions can be accurately determined. From the kinetic mode of measurement is derived a certain unit of force used in scientific calculations, and called the *absolute unit of force*; it is the force which, acting for one second, impresses a unit of velocity on a unit of mass. In Britain the unit of velocity is a foot per second, and the unit of mass the mass of the standard pound. The force of gravity in the average latitude of Britain, acting freely for one second, impresses on the body a velocity of very nearly 32·2 feet per second; hence the ordinary unit of force in Britain, being the weight of the standard pound, is very nearly 32·2 absolute units.

To calculate, in absolute units, the force which produces a given change in the motion of a body, multiply the rate of acceleration, retardation, or deviation, as the case may be, by the mass of the body. This is the only way in which forces acting amongst inaccessible bodies can be compared together.

The *masses* of bodies are known to be proportional to their weights, because of the force of gravity impressing equal velocities in equal times upon all similarly situated bodies, large and small.

The *intensity* of a force is found by dividing its magnitude by the space throughout which its action is distributed. In the case of gravity, that space is the whole volume of the body under consideration. Dividing the weight of a body in pounds by its volume in cubic feet, we obtain, so to speak, the intensity of its weight, or in other words, its *heaviness*, in pounds to the cubic foot. Pressure and tension are forces distributed over surfaces. Dividing the amount of a pressure or tension in pounds by the area of the surface over which it is distributed, in square feet or in square inches, we obtain the intensity of that pressure or tension in pounds on the square foot, or on the square inch.

Statical Moment expresses the tendency of a *couple* of forces to turn a solid body about. A couple is a pair of forces equal, parallel, and opposite, but not directly opposed; and its moment is found by multiplying either of the forces by the perpendicular distance between them, called the *arm*, or *span*, of the couple. The British unit of statical moment is a *foot-pound*: that is, the moment of a couple of forces, each of one pound, with a span of one foot.

Work consists in driving a body against a resistance: that is, a force directly opposed to its motion; and its quantity is computed by multiplying the resistance by the extent of the motion performed against it. [MACHINES, and MECHANICAL POWERS.] The British unit of work is the foot-pound: that is, a resistance of one pound overcome through one foot, or a weight of 1 lb. lifted 1 foot. The foot-pound of work must not be confounded with the foot-pound of statical moment.

Energy is the power to perform work, and is expressed in the same units. The *potential energy* of a body is the work which it is capable of doing, in moving from its actual position to another position which it tends to approach. For example, a store of a million lbs. of water, in a reservoir 100 feet above the level of the sea, and capable of being allowed to descend to that level, possesses 100 million foot-pounds of potential energy.

Impulse is the product of a force, in absolute units, into the time during which it acts on a body, in seconds.

Impetus, or *momentum*, is the product of the mass of a moving body into its velocity. The second law of motion might be otherwise expressed by saying, that the *momentum produced is equal to the impulse exerted*.

Angular Momentum is the product of the momentum of a body into its perpendicular distance from an axis about which it is revolving.

The *Actual Energy* of a moving body is the product of its momentum into half its velocity—in other words, of its mass into half the square of its velocity, divided by the number of absolute units of force in a unit of weight (in British measures, 32·2). A consequence of the second law of motion is, that the *potential energy expended in accelerating a body, is equal to the actual energy gained by the body*.

The term *action* is used to denote the product of the mass of a moving body, its velocity, and the space which it traverses.

Moment of inertia is the product of the mass of a rotating rigid body into the mean of the squares of the distances of its particles from the axis about which it rotates. This quantity, being multiplied by the half-square of the angular velocity, and divided by the number of absolute units in a unit of weight, gives the actual energy of the body.

Mechanical Centres are imaginary points at which, for the sake of convenience in calculation, forces are conceived to be concentrated, notwithstanding that in reality every force has its action more or less diffused. The most important kind of mechanical centre is the *centre of gravity* of a body, or of a system of bodies, at which, in reasoning about the equilibrium or motion of the body or system as a *whole*, its whole weight may be treated as concentrated. That point is identical with the *centre of mass*, at which, under the same circumstances, the whole mass of the body or system may be treated as concentrated. There are other kinds of mechanical centres, but they cannot here be explained in detail.

Amongst the consequences of the laws of motion are certain principles applicable to systems of bodies universally. These are the following:—

CONSERVATION OF MOMENTUM. The resultant momentum of a system of bodies is unchanged by their actions on each other.

CONSERVATION OF ANGULAR MOMENTUM (called also *conservation of areas*). The resultant angular momentum of a system of bodies is unchanged by their actions on each other.

CONSERVATION OF ENERGY. The total energy, actual and potential, of a system of bodies, is unchanged by their actions on each other (provided, in estimating quantities of energy, regard be had to the presence of energy in other forms than that of ordinary mechanical energy, such as heat).

LEAST AND GREATEST ACTION. In all motions in which the forces acting on bodies depend on their positions only, the action is either a minimum or a maximum.

In the science of mechanics there have gradually come to be included mechanical theories of various physical phenomena whose mechanical nature is not directly obvious to the senses, such as the transmission of light and heat, and the action of heat upon the cohesion and elasticity of bodies.

The leading events in the history of mechanics as a science are—the discovery of the principles of the equilibrium of parallel forces, and of hydrostatics, by Archimedes, in the third century B.C.; the discovery of the principle of the balance of oblique forces, by Stevin, and of the laws of accelerated and retarded motion, by Galileo, both of whom flourished during the second half of the sixteenth, and first half of the seventeenth centuries of the Christian era; and the final completion of the principles of abstract mechanics, with the proof that they apply to the heavenly bodies as well as to those on earth, by Newton, towards the end of the seventeenth century. Since the time of Newton no new fundamental law has been discovered in mechanics; but the art of applying mathematical principles to mechanical questions, and the introduction of mechanical principles into the theories of physical phenomena in general, have been rapidly and extensively developed.

MECHANICS' INSTITUTE, a species of educational club, originally established by Dr. Birkbeck, who in 1800 collected an assemblage of the mechanics and engineers of Glasgow, and delivered before them a course of lectures on natural philosophy and other scientific subjects. In 1823 his idea was taken up by various noblemen and gentlemen in London, among whom should be named Lord Brougham; and the first institution of the kind, specially designed for working men, clerks, and artisans, was founded in Southampton Buildings, London. Similar establishments may now be met with in every town in the kingdom of any social or commercial importance. They are supported partly by the members' subscriptions, and partly by contributions, and include a reading-room, a lending library, a lecture room, and classes for the study of the arts and languages. 'Working men's clubs,' recently introduced, are modifications of the old Mechanics' Institutes. They are intended to be self-supporting, to be entirely managed by working men, and to furnish numerous innocent opportunities of recreation to the jaded 'children of toil.'

MECHANISM, or PURE MECHANISM, is the term introduced by Professor Robert Willis to denote that branch of Applied Mechanics which relates to the comparative motions of moving pieces in machines, considered irrespectively of the forces which act upon

those pieces, and irrespectively also of the absolute speed of those motions. For example, when the machinery of a clock is examined, the mere form and arrangement of the moving pieces is sufficient to show that the minute hand makes twelve revolutions for one of the hour hand, and the seconds hand sixty for one of the minute hand. These are facts in pure mechanism; being true independently of the number of revolutions that the hour hand or any other moving piece makes in a given time, and of the force by which the clock is driven. In order that a question regarding the motion of a body may be capable of solution by means of the principles of pure mechanism alone, the body must be either a solid of invariable figure, or a cord of invariable length.

The comparative motion of two bodies at a given instant consists of two elements; the *ratio of the velocities* of those bodies to each other, and the *relation between the directions of their motions*. When the manner in which the bodies are connected with each other is known, their comparative motion can be determined by means of the principle, that the *component velocities of a pair of directly connected points along their line of connection are equal*; and this is the direct problem of pure mechanism. The inverse problem is, to determine how a pair of bodies ought to be connected, in order that they may have a given comparative motion; and this includes amongst its particular cases the designing of the forms of the working surfaces of all pieces of machinery.

(The chief authority on pure mechanism is Professor Willis' treatise on that subject. A summary of its principles, with some of their most useful applications, is given in Rankine's *Manual of Applied Mechanics*.)

MECHLIN, Malines, or Mechelen, a large town in the Belgian province of Antwerp, 13 miles by railway N. of Brussels, and 75 miles E. of Ostend, stands on the Dyle, a navigable feeder of the Scheldt, in $51^{\circ} 2' N.$ lat., $4^{\circ} 29' E.$ long., and has a population of 33,855. The city is well built and remarkably clean. The cathedral, which was built in 1451, and has a tower 370 feet high, the palace of the archbishop, who is primate of Belgium, the arsenal, which contains a cannon foundry, the town-house, and the church of the Jesuits, are the chief public buildings. There are also a Franciscan convent, and an asylum for 800 widows. In the cathedral is the celebrated painting of the 'Last Supper,' by Rubens. The town is the residence of a military commandant, and has a diocesan college, a Roman Catholic university, an academy of painting and architecture, and a society of fine arts. Mechlin is a place of great trade, and was formerly famous for its lace manufactures, but this branch of industry has greatly declined, and at present the principal things made here are shawls, woollen stuffs, starch, tobacco, and beer. An extensive trade in corn, flax, and oil is also carried on. There is water communication with Louvain by means of a canal, which is navigable for vessels of 160 tons, and the city also constitutes an important central point of junction for the entire Belgian system of railways.

MECHOACAN, or MICHOCACAN. [MEXICO.]

MECKLENBURG, a country in North Germany, lying between $53^{\circ} 8'$ and $54^{\circ} 2' N.$ lat., and between

10° 40' and 13° 45' E. long., consisting of the grand-duchies of Mecklenburg-Schwerin and Mecklenburg-Strelitz, and the principality of Ratzeburg, is bounded N. by the Baltic, E. by Prussia, S. by Prussia and Hanover, and W. by Lauenburg and Lübeck.

The surface of Mecklenburg may be described generally as a plain; the soil is fertile, and the pasture excellent; cattle are extensively reared, and cavalry horses are exported. The forests produce some excellent timber, and fish abound on the coast and in the lakes. Wheat, rye, barley, oats, peas, and rapeseed, are raised in large quantities for exportation—a great proportion of the barley being sent away in the shape of malt. The climate is moist, but healthy and temperate, though the winters are often severe.

Agriculture is very flourishing over the whole country. A considerable part of the surface is covered with lakes; the largest of these, Müritz, is 18 miles long by 8 broad. The chief rivers are—the Warnow, which is about 100 miles long, and falls into the Baltic Sea at Warnemünde, below Rostock; the Recknitz, which falls into the Baltic further east; the Elde and the Sude, feeders of the Elbe, which touches the south-western boundary at two points.

The grand ducal house of Mecklenburg is the only reigning family in Europe of Slavonic origin, and claims to be the oldest sovereign house in the western world. In their full title, the grand dukes style themselves Princes of the Vandals; and they trace their descent to Genseric, king of the Vandals, who died in 477, and whose offspring settled on the southern shores of the Baltic as rulers of Mecklenburg. One of their descendants, Burewin, obtained the hand of Matilda, daughter of Henry the Lion, and through the influence of the latter was enrolled among the princes of the Holy Roman Empire. They received the ducal title from the Emperor Charles IV. in 1340, and assumed that of Grand Duke by permission of the Congress of Vienna, in 1815. Previous to 1701, Mecklenburg-Schwerin and Mecklenburg-Strelitz formed but one state; at that date the separation of the latter took place, in favour of a younger son of the reigning duke. There being no law of primogeniture at the time, the Diet was unable to prevent the division of the country, which was protested against by subsequent dukes of Mecklenburg-Schwerin without avail.

MECKLENBURG-SCHWERIN comprises an area of 4834 square miles, and had, in 1862, 551,761 inhabitants, the great majority of whom are Lutherans. Although the country is but thinly populated, emigration is carrying off large numbers of the inhabitants, and the population is actually decreasing. This causes great uneasiness amongst the landed proprietors and farmers, for during harvest time hands are scarce, and are likely to become still more so. It is not, however, to be wondered at, for the agricultural population are little removed from the condition of serfs. At the meeting of the Diet, in April, 1864, a bill was passed investing all landed proprietors with power to condemn the labourers on their estates for simple 'neglect of service' to a week's imprisonment, and, besides, 'twenty-five blows with a stick.' The bill became law in May, 1864. There are numerous restrictions on marriage, in consequence of which the proportion of illegitimate children is

greater than in any other part of Germany, and is, moreover, increasing from year to year, so that on an average, one out of every four children born is now illegitimate. In education, also, the grand duchy is behind all other states of the Confederation.

The grand duke has no civil list, or any other grant from the country. His income consists of a large part of the revenues of the state domains, and is valued at above 120,000*l.* per annum. The crown estates altogether comprise nearly one-fifth of the territory of the duchy, and are valued at nearly 12,000,000*l.* They are looked upon, in all respects, as the private property of the duke. The political institutions of the grand duchy are of an entirely feudal character. Nearly the whole legislative power and part of the executive is in the hands of the proprietors of Rittergüter, or knight's estates, numbering 624. Seldom more than one-fourth of these, however, exert their privileges and take their seats in the Diet. To these representatives of their own property are joined thirty-nine members, nearly all burgomasters, delegated by the municipalities and corporate bodies of a like number of towns. The great bulk of the population is without political rights. The Diet meets in annual session, and every two years forms a joint assembly with the states of Mecklenburg-Strelitz, in common legislation for both duchies. The executive is represented in a ministry appointed by and responsible alone to the grand duke. No official budget has ever been published. The statements of public income and expenditure made by statistical writers are grounded on mere supposition, and vary considerably. The expenditure, probably, amounts to about 125,000*l.* per annum. The predominating form of religion is the Lutheran.

To the army of the Confederation, Mecklenburg-Schwerin contributes 5967 men, of which 4693 are infantry, 747 cavalry, and 527 artillery. The actual force kept under arms amounts to about 5500 men, who are raised by conscription, and the purchase of substitutes is permitted. Six years is the nominal period of service, of which two-thirds are allowed on furlough. The commercial navy of Mecklenburg-Schwerin consisted, on December 31, 1864, of 419 vessels, of a total burthen of 151,740 tons. The greater number of these vessels, namely, 372, of a tonnage of 135,612, belonged to the port of Rostock.

The number of vessels which entered and cleared from Mecklenburg-Schwerin in the year 1864 was as follows:—

	Arrived.	Departed.	Tonnage.
Port of Rostock, .	520	464	71,547
Do. Wismar, .	244	254	31,311
Total, .	764	718	102,858

Of these only 81 were British, the greater part being Danish and Swedish. The wheat and flour exported by sea is almost all sent to England at the average price of 38*s.* to 40*s.* per quarter. The total value of all the exports to the United Kingdom in 1864 was 324,564*l.* In the import trade the coal from England is the most important, and has, for some years, been considerably increasing. The value of all the home produce of the United Kingdom received direct in 1864 was 51,252*l.*, but the great mass of imports into Mecklenburg comes by rail from Ham-

burg—for instance, all manufactures, and a great quantity of coffee, sugar, rice, &c.

The following are the principal towns of the duchy:—

Bützow is a decayed town of 3894 inhabitants, some of whom are engaged in manufactures of paper and playing cards.

Doberan, a bathing-place and market town, containing the summer residence of the grand duke, about 2 miles from the Baltic, and 40 miles N.N.E. of Schwerin, has mineral springs and baths, at a temperature of 42° Fahr. Population, 3350.

Güstrow is one of the finest towns in the grand duchy. It was formerly the residence of the princes. The most remarkable buildings are the cathedral, containing some costly monuments of the reigning family; and the old palace (now a house of correction), described as the finest princely residence of the middle ages in Mecklenburg. The town is inclosed by walls, and is a place of considerable commercial importance, having from fifty to sixty factories of various kinds, and many breweries and distilleries. Population, 9100.

Ludwigslust is a market town, with a station on the Hamburg and Berlin Railway, 21 miles E. of Schwerin. It has a tobacco factory and paper mills. Population, 5000.

Malchin is between the lakes Malchin and Cumber, 24 miles E.S.E. of Güstrow. Weaving and turning are carried on here. Population, 4500.

Parchim is 23 miles S.E. of Schwerin, on the Elbe, and has manufactures of woollen cloths, leather, chicory, straw hats, and tobacco. Population, 6489.

Rostock, a trading port, and the largest town in the grand duchy, is situated in 54° 5' N. lat., 12° 20' E. long., on an eminence on the bank of the river Warnow, 9 miles from its mouth in the Baltic, and at the termination of a branch of the Hamburg and Berlin Railway, 44 miles N.E. of Schwerin. It consists of the old, the middle, and the new towns, with several suburbs. The principal buildings are the arch-ducal palace; the university; the court of justice; the town-hall; and the churches of St. Mary and St. Peter: the former contains the tomb of Grotius, and possesses one of the finest organs in Northern Germany; the latter, built in the twelfth century, is remarkable for its fine steeple, 420 feet in height. The university, founded in 1419, has twenty-three professors, and possesses a library rich in Oriental and Spanish literature, theological and other schools, an anatomical theatre, laboratory, and botanic garden. Rostock is the principal trading port of Mecklenburg, and has manufactures of woollen cloth, soap, and chicory; with breweries, distilleries, vinegar, colour, and chemical factories, and sugar refineries. There is also some shipbuilding carried on here. The depth of the water in the river is from 8 to 9 feet, and vessels above that draught load and unload at Warnemünde, the out-port of Rostock. In one of the principal squares is a statue to Blücher, who was a native of this place, which was long one of the Hanse Towns, and retained, until lately, some exclusive privileges. Population (1862), 26,396.

Schwerin, capital of the grand duchy, and of Mecklenburg district, is situated on the west shore

of the lake Schwerin, and on the railway from Hamburg to Wismar, 35 miles S.E. of Lubeck. The town has a striking and important appearance when viewed from a distance. It is a long, irregular, and plain town, containing two or three fine buildings—the grand ducal palace, which is built on a peninsula in the lake, and is an old fortified structure, containing a good picture gallery, and a museum; a fine modern building appropriated to state business; and an old Gothic cathedral, 305 feet in length, and 135 in breadth. Schwerin is the residence of the grand duke. Besides the public edifices already mentioned, there are Lutheran and Roman Catholic churches, a Jews' synagogue, a mint, government offices, &c. This town is mentioned in old records of 1018 as a strong fortress. The manufactures are of vinegar, cloth, pottery, and tobacco. Population (1862), 22,919.

Sternberg, where the Diet meets once every two years, is a small place 29 miles S.W. of Rostock. Population, 1945.

Wismar, an important fortified sea-port on Walpich Bay, 18 miles N.E. of Schwerin, on a branch railway to Hamburg and Rostock. In 1864 the number of vessels belonging to the port was 47, measuring 16,128 tons. The harbour is not deep, but it is considered one of the safest in the Baltic. The town is tolerably well built: the streets being broad and well paved. The principal buildings are—several Gothic churches, a handsome modern town-hall, hospitals, schools, orphan asylum, &c. There are shipbuilding docks, and several breweries and distilleries. The exports consist chiefly of corn; the imports are mostly Swedish productions. Fishing, agriculture, and the manufacture of tobacco, sail-cloth, and linen, employ a large proportion of the population. Wismar was bought by Schwerin in 1803, of the Swedish government, for 1,200,000 dollars. It was founded in 1229, and for a time belonged to the Hanseatic League. Population, 13,128.

MECKLENBURG-STRELITZ lies to the east of Mecklenburg-Schwerin, and covers an area of 997 English square miles, of which 527 belong to the grand duke, nearly one-fourth of it being forest lands. The country is flat, and similar in its features to Mecklenburg-Schwerin; but owing to its being further from the sea, the climate is less humid and changeable.

The population, which, according to the last census, numbered 99,060, is decreasing. The loss, amounting to 690 in eight years, is caused by a strong tide of emigration. The country is divided into two separate provinces, the first of which, Stargard, has a Diet composed of landowners, while the second, Ratzeburg, has no representative institutions whatever. The Stargard Diet periodically joins the legislative assembly of Mecklenburg-Schwerin. Only the possession of a Rittergüt, or knight's estate, gives right to a seat in the Diet, to which neither the towns nor rural populations send any deputies. There are sixty-two such proprietors in the province of Stargard, only a small number of which, however, choose to take their seats. The executive is entirely in the hands of the grand duke, who swallows up the whole of the public revenue.

Mecklenburg-Strelitz contributes 197 men, includ-

ing 200 artillery, to the army of the Germanic Confederation; but by an arrangement with the grand duke of Mecklenburg-Schwerin, the latter has undertaken to furnish the artillery, in return for twice the number of foot-soldiers. The troops are raised by conscription, and serve for a period of six years. The Congress of Vienna permitted Duke Charles Frederick of Mecklenburg-Strelitz to adopt the title of Grand Duke, notwithstanding the exceedingly limited extent of his territory. He is, however, one of the wealthiest of German sovereigns, more than one-half of the country being his own private property. A territory of 7 square miles, with 10,000 souls, which was added to the newly created grand duchy in 1815, was sold by the late grand duke George to Prussia, in 1819, for the sum of 1,000,000 thalers, or '100 thalers per soul.' It is impossible at present to decide what changes will be effected in this and other small German states by the late war between Prussia and Austria (1866).

The principal places are the following:—

New Brandenburg, a pretty, circular town, with broad straight streets, is built near the Tollense lake; manufactures of woollen cloth, cards, paper, and tobacco are carried on. The grand duke has a palace in the town, and a country house in the neighbourhood. Population, 10,000.

Stargard (called Old Stargard) is a small town with 1618 inhabitants.

Strelitz, capital of the grand duchy, situated between the lakes Zierker and Glambeck, 60 miles N.N.W. of Berlin, consists of the old and new towns, which, though one mile apart, form one city. Old Strelitz was formerly the ducal residence, and has a large horse market. New Strelitz, founded in 1733, is built in the form of a star, with eight divergent rays. This town is the usual residence of the grand ducal court. The most remarkable edifice is the ducal palace, which contains a library of 50,000 volumes, and a curious collection of German antiquities. The inhabitants chiefly depend for their support on the expenditure of the court. In the town are a theatre, college, mint, and other government offices. The united population of the two towns is 10,479.

Ratzeburg, a small principality belonging to Mecklenburg-Strelitz, and situated between Schwerin, Lübeck, and Lauenburg, is traversed by the river Trave, and is bounded on the west by the lake of Ratzeburg, by means of which timber, corn, pulse, flax, and cattle are sent to Lübeck for exportation. The inhabitants also carry on considerable fisheries. Ratzeburg, the chief town, mostly belongs to Lauenburg, with the exception of the cathedral and the hospital, which belong to Strelitz. It is the seat of administration of the Duchy of Lauenburg, and has a population of 3250. (*The Statesman's Year-Book*, 1866; *Almanac de Gotha*, 1866; *Consular Reports*, &c.)

MECONIC ACID (Gr. *μήκων*, 'the poppy'), a substance which is found only in opium, where it exists in combination with the alkali Morphia. Meconic acid is a crystalline substance, which acts on litmus paper, and has a sour taste; it is soluble in four times its weight of water, and also in alcohol. The crystals do not alter by exposure to the air, but when heated to 212° they lose 21·5 per cent. of water, and become opaque. When strongly heated,

it is totally vaporized and decomposed. It appears to consist of 3HO, C₁₄, HO₁₁.

The salts which contain this acid are called *meconates*. The chief among them are combinations of the acid with Ammonia, Potash, Soda, Lime, Magnesia, Barytes, and Iron: the whole of these crystallize.

When a solution of meconic acid is heated to ebullition, carbonic acid is evolved, and a brownish solution results; this consists of colouring matter and *metameconic acid*. When a meconate, as of potash or lime, is boiled with hydrochloric acid, no colouring matter results, and yet metameconic acid is formed. This acid is in hard anhydrous grains. *Pyromeconic acid* is a crystalline body, fusible between 248° and 257°, and then flows like oil: it is entirely soluble at a moderate temperature. The relation between the three acids is thus shown:—

MECONIN, *Opimyl*, a neutral principle existing in opium. It is colourless and inodorous, is at first tasteless, but afterwards acid; it is soluble in water, alcohol, and ether, and crystallizes well in any of them; the crystalline form is a six-sided prism with dihedral summits; it fuses at 194°, and is volatilized at 310°, without undergoing any change of properties.

MECONO'PSIS (from *μήκων*, 'a poppy,' and *ψις*, 'a resemblance'), a genus of plants belonging to the natural order *Papaveraceæ*. There is only one species, *M. Cambria*, the Welsh Poppy, and this is a native of Great Britain, but it is a rare plant. It is also found in many parts of Europe. It has yellow flowers, is an ornamental plant, and may be introduced into the garden. It will grow in a rich light soil, in a shady situation. It may be propagated by dividing the roots, or by seeds.

MEDAL (Ital. *medaglia*). Numismatists have usually given the name of medals to those coins that have been struck or cast for particular purposes and on extraordinary occasions, in commemoration of victories, treaties, coronations, and similar important events, or in honour of remarkable persons, in distinction to those which have been issued and generally circulated as money. [COIN.]

Greek medals and medallions are very rare, few being known of earlier date than the establishment of the imperial power at Rome, and when Greece was under Roman dominion. Some of Sicily are not, however, so scarce; they are of very fine design and workmanship, and deserve the careful attention of the connoisseur. Roman medals are more common. Many of great excellence and in high preservation are contained in the collection of coins in the British Museum.

The earliest examples of modern medals and medallions seem to be of the fifteenth century, though there is one remarkable exception to this in a medal of David II., king of Scotland. It is of gold, and was probably executed during that prince's captivity in England, sometime between the years 1330 and 1370. From the fifteenth century there is a succession of medals in most European countries. A

gold medal of the council of Florence, dated 1439, is one of the earliest. A still earlier one, if the date 1415 is correct, is of John Huss; but some doubts have been entertained of its authenticity. Vittore Pisano, a painter of Verona, is celebrated as the restorer of the art at that period; but the medal alluded to of David of Scotland seems to prove that it was practised before his time. Pisano's medals are very large, and are all cast. They are usually inscribed 'Opus Pisani Pictoris.' It is curious that he should always refer to his being a painter while exercising a totally distinct branch of art. The papal medals commence properly with Paul II., who began to reign in 1464; those of pontiffs who lived prior to that date having been added to the collection by successors. The German medals commence in 1453, and are very numerous. The Sicilian medals appear as early as 1501. The Spanish medals begin in 1503. The earliest of Venice appear in 1509; and those of Denmark in 1516. The first Dutch medals seem to be of 1566, and they are remarkable for the elaborate views, maps, and plans that are engraved on many of them.

The French medals do not exhibit any remarkable excellence till the reign of Louis XIV. gave an impulse to the art, and we find his entire life illustrated by medals; some of them are well designed and finely executed. The medallion history of Napoleon deserves notice in the series of medals of France. It is of great extent, and is for the most part honourable to French art.

The series of English coins and medals is one of the most perfect. The first medal is of 1480. It is of a large size, and executed in the early Italian manner. On one side is a portrait with *IO. KENDAL. RHODI. TURCUPELLARIUS*; on the reverse the arms of Kendal, with the inscription, *TEMPORE OBSIDIONIS TURCORUM, MCCCC.LXXX.* The next English medal is of the time of Henry VIII. It is of gold, and bears the king's portrait on one side, with an inscription on the reverse. The first coronation medal appears in the reign of Edward VI. The medals of Queen Mary are numerous, and very interesting from the devices they bear. The Scotch coronation medal of Charles I. is of gold, and was struck at Edinburgh. It is remarkable as being the first struck in Britain with a legend on the edge.

Some remarks on the manner of engraving dies for medals and coins will be found in the article on *Intaglio*. [*INTAGLIO*.]

MEDALLION, a medal of a large size.

MEDALLION, in architecture, any circular or oval tablet bearing on it objects represented in relief, as figures, heads, animals, flowers, &c.

MEDE, JOSEPH, was born at Berden in Essex, in the year 1586, and died in 1638. In 1602 he entered Christ's College, Cambridge, and took his degree of M.A. in 1610, and that of B.D. in 1618. He devoted his entire life, in the retirement of his college, to his studies, and has left, as the chief result of his application, his '*Clavis Apocalyptica*,' said by Bishop Hurd to have been the first rational attempt to explain the Apocalypse. This work was translated by Mr. T. Bransby Cooper in 1833.

MEDEA or **MEDEIA**, in Greek mythology, a daughter of *Eetes*, king of Colchis, who wedded Jason the Argonaut, and by her marvellous wisdom

assisted him to obtain the great prize of the Golden Fleece. But being deserted by Jason for the sake of Glauké, the daughter of Creon, king of Argos, she murdered her two children, poisoned the unfortunate Glauké, and then fled from the land in a chariot drawn by dragons. This is obviously one of the solar legends, and Medea's destruction of her children symbolizes the sun's pernicious influence upon the plants which it has first produced.

MEDEYAH. [*ALGIERS*.]

ME'DIA, a country of ancient Asia. In the time of Strabo it was divided into two divisions, Great Media and Media Atropatène. Great Media, which is a high table-land, had a good climate and a fertile soil. It was separated on the W. and S.W. from the low country watered by the Tigris and Euphrates by a range of mountains called Zagros and Parachotras; on the E. it was bounded by a desert and the Caspian mountains (the modern Elburz range); and on the N. and N.W. by the Cadusii, Atropatene, and the Matieni, thus answering for the most part to the modern Irak Ajemi. Atropatene, which corresponds to the modern Azerbaijan, extended as far north as the Araxes (*Aras*).

The principal town of Great Media was Agbátana, or Ecbátana (Hamadan), the summer residence of the Persian kings. [*ECBATANA*.] In the N.E. of Great Media, near the Caspian gates, was the town of Rajæ (now Rai), afterwards called Európus by the Macedonians, and Arsacia by the Parthians, which was founded, or rather colonized, by the Macedonians under Seleucus Nicátor.

The chief town of Atropatene was Gaza, or Gaziki, as it is called by Ptolemæus, at no great distance from the modern Tauris, or Taubreez. N.W. of Gaza was a salt lake, called Spauta, or Martianus (Shahey, or Urumiyeh).

According to Herodotus the Medes were originally divided into six tribes, one of which was the Magi.

Media originally formed part of the Assyrian empire, but its history as an independent kingdom is given differently by Herodotus and Ctesias. According to Herodotus there were four kings of Media: 1. Deioces, who reigned B.C. 710-657. 2. Phraortes, B.C. 657-635, greatly extended the Median empire, subdued the Persians and many other nations, but fell in an expedition against the Assyrians of Ninus (Nineveh). 3. Cyaxares, B.C. 635-595, extended the boundaries of the empire as far west as the Halys. In an expedition against Nineveh he was defeated by the Scythians, who had made an irruption into southern Asia. After the expulsion of the Scythians, he took Nineveh, and subdued the Assyrian empire, with the exception of the Babylonian district. 4. Astyages, B.C. 595-560, who was dethroned by his grandson Cyrus, and Media reduced to a Persian province.

The Medes revolted during the reign of Darius II., the father of the younger Cyrus, about B.C. 408, but were again subdued. On the downfall of the Roman empire they formed a part of the kingdom of the Seleucidæ, and were subject to the Parthians.

MEDIATISATION, a term used to signify the process of absorption of the smaller German principalities into the larger neighbouring states, by which they lost their *direct* connection with the empire, and became only *mediately* dependent upon it.

MEDICA'GO (from *μνδική*, the Greek name of one of the species), a genus of plants belonging to the natural order *Leguminosæ*. The species are exceedingly numerous, upwards of eighty having been described.

M. sativa, Lucern, is super-eminent as an artificial grass in temperate climates, and a most valuable plant for feeding cattle. It was in high repute among the ancients. The authors 'De Re Rustica,' speak of it with enthusiasm, and all over the continent of Europe, wherever husbandry has made any progress, it is in high reputation. Lucern is a plant which will not bear extreme frost nor superabundant moisture, and its cultivation is therefore restricted to mild climates and dry soils; but where it thrives, its growth is so rapid and luxuriant, that no other known plant can be compared to it. In good deep loams lucern is the most profitable of all green crops; when properly managed, the quantity of cattle which can be kept in good condition on an acre of lucern, during the whole season, exceeds belief. It is no sooner mown than it pushes out fresh shoots, and wonderful as the growth of clover sometimes is in a field which has been lately mown, that of lucern is far more rapid.

Lucern, sown in a soil suited to it, will last for many years, shooting its roots downwards for nourishment till they are altogether out of the reach of drought. In the driest and most sultry weather, when every blade of grass droops for want of moisture, lucern holds up its stem, fresh and green as in a genial spring. The only enemies of this plant are a wet sub-soil and a foul surface. The first is often incurable; the latter can be avoided by good cultivation.

M. falcata is a native of Europe on dry mountainous pastures. In England it is a rare plant, but is occasionally found on dry gravelly banks and old walls. This species is said to be the lucern which is cultivated in Switzerland. *M. lupulina*, Black Medick, or Black Nonsuch, is a native of Europe in meadows, pastures, and waste ground, and is plentiful in Great Britain. It affords excellent fodder for sheep, and must be treated in the same way as lucern. *M. arborea*, Tree Medick, is a native of the south of Europe, and appears to be the *κρίσιος* of Theophrastus, 'Hist. Plant.' lib. 4, cap. 5. Besides the first three species, described above, *M. maculata*, *M. minima*, and *M. denticulata*, are natives of Great Britain.

MEDICAL DEPARTMENTS of the Army and Navy are very important branches of the public service. That of the Army is under the control of a skilful and experienced officer, usually stationed at head-quarters, and called Director-general. His pay is 1500*l.* a year. The medical staff has charge of detachments, hospitals, &c., and comprises 6 inspectors-general, 22 deputy inspectors-general, 19 staff-surgeons-major, 46 staff-surgeons, 194 staff-assistant-surgeons, and 17 apothecaries and dispensers. There are also about 400 regimental surgeons, and 450 medical officers employed with the army in India. Every battalion has a surgeon and assistant-surgeon wherever situated, and an extra assistant when in India or the tropics. The total cost of the medical establishments, services, and supplies of the British army in 1866, exclusive of the regimental surgeons, was 246,544*l.* The medical department

of the navy is also governed by a director-general, whose pay is 1800*l.* per annum. The staff comprises similar ranks to that of the army, but the medical officers are not so numerous, as the sea service is much more healthy than the land service, and the navy is not so large as the army.

The total cost of the naval medical establishments at Haslar, Plymouth, Yarmouth, and Haulbowline, for 1866, was 14,238*l.*; the marine infirmaries at Woolwich, Chatham, Portsmouth, Plymouth, and Deal, 5437*l.*; the medical establishments at Malta, Bermuda, Jamaica, Cape of Good Hope, and Hong-Kong, 8452*l.* For medicines and medical stores for the navy in the same year the cost was 64,800*l.*

MEDICAL PRACTITIONERS. The statute 21 and 22 Vict. c. 90 relates to the medical profession, and enacts that those who falsely pretend to be, or take, or use the title of a physician, doctor of medicine, licentiate in medicine or surgery, surgeon, general practitioner, or apothecary, shall be liable to a fine of 20*l.* or imprisonment. All duly qualified persons are now registered; and if they do not register themselves they cannot fill certain offices, and cannot sue for their fees. By this Act, too, physicians are allowed to sue for their fees as legal debts, which before were considered honoraria, to be paid beforehand, like the fees of barristers.

ME'DICI, FAMILY OF. The oldest member of this family, of whom there is any distinct record, is Giovanni de' Medici, who, at the head of 100 Florentines, forced his way through the Milanese army in 1251. Other members of the family held important offices successively in Florence. The founder, however, of that greatness which his posterity enjoyed for several ages was Giovanni de' Medici, the great-grandfather of Lorenzo the Magnificent. By a strict attention to commerce he acquired great wealth; by his affability, moderation, and liberality, he secured the confidence and esteem of his fellow-citizens. Without seeking the honours of the republic, he was gratified with them all; and his lavish charity procured him the splendid title of the 'father of the poor.' He died in 1428, leaving two sons, Cosmo, born in 1389, and Lorenzo, in 1394, from the latter of whom is derived the collateral branch of the family, which in the beginning of the sixteenth century obtained the absolute sovereignty of Tuscany.

Even in the lifetime of his father, Cosmo had engaged not only in the extensive commercial transactions by which the family had acquired its wealth, but also in the affairs of state. The authority which Cosmo and his descendants exercised in Florence, during the fifteenth century, consisted rather in influence than in any definite power. A party headed by Rinaldo d'Albizi attributed the unfortunate result of the war against Lucca to Cosmo, and obtained his banishment in 1433; but he was recalled in triumph within a year to enjoy for the remainder of his life uninterrupted prosperity. Though a private citizen, he surpassed almost all the princes of Europe in his munificent patronage of literature and the fine arts. He established at Florence an academy for the explanation of the Platonic philosophy, at the head of which he placed the celebrated Marsilius Ficinus. By means of foreign correspondence, he collected the Greek, Latin, and Oriental MSS. which formed the basis of the Laurentian

library. He also endowed numerous religious houses, and built an hospital at Jerusalem for the relief of distressed pilgrims. By his prudent conduct and benevolence he acquired the title of 'father of his country,' which was inscribed upon his tomb; an appellation which, as it was founded on real merit, has ever since been attached to his name. He died August 1, 1464. He had two sons, Giovanni and Piero; and a natural son, Charles, who was canon of Prato.

Giovanni de' Medici was one of the Florentine ambassadors who were sent, in 1455, to take the necessary oaths to Pope Calixtus III. He died in 1463. Piero de' Medici succeeded to Cosmo's fortune and authority at Florence. He was nearly falling a victim to a base plot contrived by his minister Neroni. Piero died December 3, 1469, leaving by his wife, Lucretia Tornabuoni, two sons and two daughters, Lorenzo, Giuliano, Bianca, and Giovanna.

At the death of Piero de' Medici, his two sons inherited his property; but Lorenzo succeeded him as head of the republic. In 1472 he re-established the academy of Pisa: for this purpose he contributed a large sum from his private fortune, in addition to that granted by the state of Florence. Lorenzo, like his father, narrowly escaped a plot laid to assassinate him, by the Pazzi family, and his brother fell a victim to the conspirators. The citizens of Florence were so indignant at the atrocity that they killed two members of the Pazzi family, and hung the bishop of Pisa in his robes for assisting in the plot. This incident led to a war with Pope Sixtus IV., which was continued with varying fortune until 1480. Lorenzo now secured to the republic of Florence a degree of tranquillity and prosperity which it had scarcely ever known before; and by procuring the institution of a deliberative body, of the nature of a senate, corrected the democratical part of its constitution.

Lorenzo distinguished himself above all his predecessors by the encouragement of literature and the arts. His own productions are sonnets, canzoni, and other lyric pieces; some longer works in stanzas, some comic satires, carnival songs, and various sacred poems. Although the ancestors of Lorenzo laid the foundation of the immense collection of manuscripts contained in the Laurentian library, Lorenzo has the credit of adding very largely to the store. On the discovery of the art of printing, Lorenzo appreciated its importance. At his suggestion several Italian scholars devoted their attention to collating the manuscripts of the ancient authors, for the purpose of having them accurately printed. On the capture of Constantinople by the Turks, many learned Greeks took refuge in Italy; and an academy was established at Florence for the purpose of cultivating the Greek language. Lorenzo also augmented his father's collection of the remains of ancient art. He appropriated his gardens in Florence to the purpose of an academy for the study of the antique. To this institution, more than to any other circumstance, Roscoe ascribes the sudden and astonishing advance which, toward the close of the fifteenth century, was evidently made in the arts, and which, commencing at Florence, soon extended itself to the rest of Europe. Lorenzo died in 1492. A graphic account of his death-bed interview with Savonarola is given by Bur-

lacci. Lorenzo acknowledged the commission of three principal offences: the sacking of Volterra, the appropriation of charitable funds, and the execution of innocent persons on suspicion of being implicated in the Pazzi conspiracy. The priest-reformer refused him absolution until satisfied of three things: his sincere faith in God, his restitution of wealth improperly acquired, and the restoration of Florentine freedom. The dying statesman assented to the two first demands, but to the third made no reply, and turned his face to the wall. At the time of his death he was forty-two years old. His life has been written in English by Thomas Roscoe, and the incidents of his age described by Thomas Adolphus Trollope in his 'History of the Commonwealth of Florence.' By his wife, Clarice Orsini, Lorenzo had three sons (Piero, Giovanni, and Giuliano) and four daughters, who arrived at the age of maturity. Piero was born February 15, 1471, Giovanni in 1475, and Giuliano in 1478. Giovanni was afterwards known under the name of Leo X.; and Giuliano, having allied himself by marriage to the royal house of France, became duke of Nemours.

Giuliano, the brother of Lorenzo, left an illegitimate son, who was brought up under the protection of Lorenzo, and was destined to act an important part in the affairs of Europe. The final extinction of the liberties of Florence, the alliance of the family of Medici with the royal house of France, the expulsion of Henry VIII. of England from the bosom of the Roman Church, are principally to be referred to this illegitimate son of Giuliano de' Medici, who under the name of Clement VII. guided the bark of St. Peter through a succession of the severest storms which it has ever experienced.

Piero, the eldest son of Lorenzo, succeeded him in the administration of Florence. The invasion of Italy by the French is matter of history. The plundering of the palace of the Medici, and the dispersion of the valuable library which they had collected, are among the misfortunes which befel Florence during the same period. Piero, by his base treaty with Charles VIII., prepared the downfall of the state which his forefathers had contributed to raise and enlighten.

The Medici were expelled from Florence by the turbulent citizens in 1527, but restored by Pope Clement VII. and Charles V. in 1530. Two years later, the pope's natural son, Alessandro de' Medici, became duke of Florence, and on his assassination by his kinsman Lorenzaccio in 1537, was succeeded by Cosmo I., born in 1519, died in 1574. This able, prudent, and unscrupulous man greatly extended his power, crushed the liberties of Florence, but as some compensation extended its territories, and finally, in 1564, by papal grant, assumed the title of grand duke of Tuscany, a title which was extinguished by the erection of the Italian kingdom in 1860. [ITALY.]

MEDICINE, a science, the object of which is the cure of disease and the preservation of health. Occasionally it is used to comprehend all the branches of the healing art; at others, to comprise one great division, in contradistinction to *surgery* and *obstetrics*. Medicine, in this sense, includes many branches, the chief of which are anatomy, physiology, pathology, therapeutics, hygiene, materia medica, and pharmacy. The earliest records of the practice

of medicine are extremely obscure. Among the Jews it appears to have been entirely confined to the priests, and the whole art seems to have consisted in the prevention of contagion by isolation and cleanliness, and the administration of a few uncertain remedies. The Egyptians, according to the account of Herodotus, must have made some little progress; purging medicines and emetics were well known to them and much used; and such was the subdivision of labour, that there were physicians for every separate complaint, some for the eyes, others for the head, others for the teeth, others for the abdominal parts, and others for diseases which did not manifest themselves by outward visible symptoms. (Herod., ii. 84.) It appears, however, that in the time of Darius the son of Hystaspes, the Greeks possessed at least more skill than the Egyptians. (Herod., iii., 129.) The Greeks probably derived their knowledge of medicine, with that of many other arts, from Egypt, whence Chiron, the Centaur of their fables, is said to have first introduced it among them. His pupil Æsculapius [ÆSCULAPIUS] so much improved the art, that he was deified; and Machaon and Podalirius, his sons, accompanied the Grecian army to the siege of Troy. The descendants of Æsculapius were for many years the chief practitioners of medicine: they were called Asclepiadæ, and were the priests of the temples erected in honour of their progenitor, to which the sick were accustomed to resort for advice and the application of remedies.

In the sixth century before the Christian era, medicine, with other sciences, began to be more philosophically studied in Greece, and among the first of those who devoted much of their time to the investigation of the structure and functions of the animal body was Pythagoras. His pupils Democritus and Heraclitus appear also to have added considerably to the knowledge both of anatomy and of practical medicine, and their contemporary, Herodicus, first introduced the practice of gymnastic exercises, which afterwards formed so large a part of medical treatment. But the most remarkable man in the history of medicine in Greece was Hippocrates, one of the Asclepiadæ, who was born at Cos (where one of the chief temples was erected), B.C. 460, and was the pupil of Heraclitus and Herodicus. [HIPPOCRATES.] His sons Thessalus and Draco, and his son-in-law Polybius, were the most renowned of his descendants, and they are generally regarded as the founders of the medical sect or school which was called the Hippocratic or Dogmatic sect.

The establishment of the Alexandrian school of philosophy forms the next most important epoch. The science of medicine was assiduously cultivated, and the human body was first dissected in Alexandria by Erasistratus and Herophilus. [HEROPHILUS.] The former was the pupil of Chrysippus, a violent opponent of the Hippocratic school, and a bold innovator in medicine, with whom probably originated the schism in consequence of which, for some centuries, every physician ranged himself in one of two sects, the Dogmatists and the Empirics.

During the early periods of the Roman empire, medicine seems to have been little cultivated, and, according to Pliny (xxix. 1), Rome was for 600 years without professed physicians, though not entirely

without medical knowledge. The first individual of any eminence who practised medicine in Rome was Asclepiades of Bithynia [ASCLEPIADES], who lived in the century before the commencement of the Christian era; but he does not appear to have advanced the knowledge of the science. He was succeeded by his pupil Themison, the founder of a sect called Methodics, who held doctrines nearly intermediate between those of the Dogmatists and of the Empirics.

About two centuries later the Methodics were divided into numerous sects, as the doctrines of particular physicians became more generally received. The chief of these sects were the Pneumatics and the Eclectics. The former are represented by their most eminent writer, Areteus [ARETEUS], who lived in the reign of Vespasian, and the chief points of their doctrines are detailed in his life. Of the Eclectics, the most celebrated was Archigenes, of Apamea, who practised at Rome in the time of Trajan. But the most remarkable writer of this age was Celsus, in whose work, 'De Medicinâ,' the progress and condition of medicine previously to and during his life are amply detailed. [CELSUS.]

The individual whose history forms the next chief epoch in the history of medicine is Galen. [GALEN.] For a long time after his death physicians were chiefly occupied in commenting on his works, and imitating, as closely as they could, his practice. His writings were regarded as ultimate authority, and everything that seemed opposed to them was at once rejected. From the time of Galen to the seventh century the only names of any repute (and theirs is but small) are Sextus Empiricus, Oribasius, Aetius, Alexander Trallianus, and Paulus of Ægina; and, after the death of the last of these, no medical work of the least merit was published in the Greek language.

From the seventh to the twelfth century the only nation in which medicine made any progress, or was even prevented from retrograding, was the Arabian. It appears that in the conquest of Alexandria some books were saved from the burning of its magnificent library, and that among them were the writings of Hippocrates and Galen. The latter were soon translated into Arabic and diligently studied; and all the earliest Arabian works on medicine, as those of Ahrun in the eighth, and Serapion in the ninth century, are little more than transcripts of those of Galen. The most illustrious names of this school are Rhazes, Ali-Abbas, Avicenna, Mesne, Albucasis, Avenzoar, and Averroes.

From the decline of the Arabian school in the twelfth century to the beginning of the fifteenth, the history of medicine presents few circumstances of interest. The dissection of the human body was first publicly practised by Mondini at Bologna, about the year 1315; and at about the same time lived Gilbert, the first English writer on medicine who acquired any repute.

In the fifteenth century the sect of chemical physicians arose, and their doctrines, under the bold advocacy of Paracelsus, who publicly burnt the writings of Galen, obtained considerable credit and numerous supporters. In the middle of the sixteenth century the most important improvement commenced in the diligent and accurate study of anatomy by

Vesalius, who, disregarding the general obloquy which he incurred, carefully studied the structure of the most important parts of the human body.

From the time of Vesalius, the study of anatomy was diligently pursued, and in the early part of the seventeenth century was rewarded by several of the most interesting and important discoveries; as that of the circulation by Harvey, of the absorbents by Asellus, of the process of respiration by Malpighi, and numerous others. Among the most celebrated men of the seventeenth century, may be enumerated Glisson, Bartholin, Rudbeck, Fabricius, Hooke, Sylvius, Willis, Riolanus, Fallopius, Bellini, and Sydenham. Somewhat later appeared Stahl, Hoffmann, and Boerhaave.

Among the pupils of Boerhaave were Van Swieten and Haller. Before the time of Haller, the cases of Harvey, Glisson, Malpighi, and others, who devoted themselves to the simple observation of facts and the evident deductions from them, were exceptional; but since his time, the exceptions have rather been those who, with a comparative neglect of observation, have endeavoured only to find or support some theory by which all the phenomena they met with might seem explained. Haller's contemporary Cullen [CULLEN], though he yielded much more to theory, was of eminent service in the study of practical medicine; and his opponent Brown is acknowledged to have introduced many useful lessons in the same branch of the study.

With the gradual oblivion of the hypotheses of both Cullen and Brown, the theoretical study of medicine may be considered to have entirely ceased, and in the present day we may certainly be said to be without any general medical theory. From the time of Haller, medicine has acquired more and more nearly the character of a science of simple observation and the patient investigation of facts.

MEDICK. [MEDICAGO.]

MEDIETAS LINGUE, a jury consisting of half foreigners, half natives, used in pleas between a foreigner and a denizen.

MEDINA, (Arabic, Medinah-el-Nebi, 'the Prophet's city'), the second holy city of the Mohammedans, and the place where their Prophet was buried, is situated in that part of Arabia which is called El Hejaz, or Hedj, about 24° 27' N. lat., and 39° 53' E. long., and about 110 miles from the town of Yembo on the Red Sea, which is the harbour of Medina. Population 5000.

The city forms an oval, about 3000 paces in circumference, and 3000 feet above sea-level. The castle is built on a small rocky elevation, and strongly fortified. The whole is inclosed by a thick wall of stone, between thirty-five and forty feet high, flanked by about thirty towers and surmounted by a ditch: it is well fortified for an Arabian town, and has always been considered the principal fortress in Hejaz. Three well-built gates lead into the town. The houses are handsome, entirely of stone, and generally two stories high. As the stone is of a dark colour, the streets have rather a gloomy aspect, and are for the most part very narrow, often only two or three paces across; a few of the principal thoroughfares are paved with stone. The diminution in the number of pilgrims of late years has caused a great part of the houses to fall into decay. There are only

two large streets which contain shops. The great mosque containing the tomb of Mohammed is the only temple. There are two fine medresses or colleges. The suburbs extend west and south, and cover a larger area than the city itself. They are separated from it by an open space, narrow on the south, but forming on the west a large public place. The greater part of the suburbs consists of large courtyards with low houses built round them, and separated from each other by gardens and plantations: they are inhabited by the lower classes of the town, and those who are engaged in agriculture. Each court-yard contains thirty or forty families, so as to form a hamlet by itself.

The town is supplied with sweet water by a subterranean canal (about 25 feet under ground) which runs from the village of Koba, about three-quarters of a mile distant in a southern direction; and there are numerous wells attached to the houses. This plentiful water-supply made Medina a considerable settlement of Arabs long before it became sacred among the Mohammedans by the flight, residence, and death of their prophet.

The mosque containing the tomb of Mohammed is situated towards the eastern extremity of the city, and, like that of Mecca, forms an open square surrounded on all sides by covered colonnades, with a small building in the centre of the square. The colonnades are much less regular than those of Mecca. Near the south-eastern corner of the mosque stands the famous tomb, detached from the walls so as to leave between it and the southern wall a space of about 25 feet, and 15 between it and the eastern wall. The inclosure which protects the tomb from visitors is formed of a very close iron railing, pierced with several small windows. This inclosure is entered by four gates, three of which are constantly kept shut, and one only is opened every morning and evening to admit the eunuchs, whose office it is to clean the floor and light the lamps. The whole of the inclosure is covered with a lofty dome, rising far above the domes which form the roof of the colonnades, and visible at a great distance from the town. As soon as pilgrims to Medina catch sight of it they repeat some prayers.

The inhabitants of Medina, like those of Mecca, are not Bedowins, but strangers who have visited the place as pilgrims and afterwards settled there, or the descendants of such strangers. Medina is not so great a place of commerce as Mecca, and the merchants are not so rich, but it has the advantage of having a considerable tract around which is fit for cultivation.

MEDITATIO FUGÆ WARRANT, in the law of Scotland, is a writ by which a debtor, supposed to be about to make his escape from the country, is arrested and kept in custody until he pay the debt, or find security to pay it, if he shall be judicially found liable to do so.

MEDITERRANEAN (or *Midland-Sea*; Lat. *Mare Internum*; Germ. *Mittelmeer*), the name of the sea between the Straits of Gibraltar to the west and the Dardanelles and Syria to the east. It is comprised between the parallels of 30° 20' and 45° 50' N. lat., and the meridians of 5° W. and 36° E. long. The distance from Gibraltar to the farthest shore of Syria is 2000 miles, and the narrowest part, between

Sicily and Africa, is 79 miles across. The Mediterranean, including the islands, occupies an area of 784,000 square miles. The surface of country of which it receives the drainage is very difficult to estimate, but may be assumed to exceed this quantity.

The shores of Syria are mountainous between Tripoli and Tyre, but present in many places a large extent of low and flat coast. The coast of Anatolia, the west portion of Asia Minor, is mountainous, rising in some parts very near the sea to 7000 and 8000 feet. About 20 leagues from the nearest coast of Syria lies the island of Cyprus. The islands of Candia, the name given by the Venetians to the ancient Crete, and of Rhodes, are also in this part of the Mediterranean. The numerous islands in the Ægean, between Greece and Asia Minor, forming the Grecian Archipelago, are subject to very heavy squalls. Their sides being steep, and the water very deep, there are in general no anchorages except in particular places. The coast of the Morea, the ancient Peloponnesus, is mountainous, some of the summits exceeding 6000 feet. The coast of Albania, including the ancient Illyricum, is more mountainous and rugged. Off this coast and the Morea lie the Ionian Islands. Proceeding northward we enter the Adriatic, the entrance of which is 40 miles broad. The shores of Dalmatia and Istria afford numerous fine harbours; and above Ragusa are studded with islands affording good anchorage.

The Greeks, especially the Hydriotes, are active sailors. They employ small vessels, half-decked, which both sail and pull, but they seldom venture to sea except in fine weather or with a fair wind. The trade to the Black Sea is chiefly carried on in Greek bottoms. But the coasting trade of the Adriatic is mainly conducted by Austrian vessels and those of the Papal States. The vessels employed are mostly trabaculos, a kind of lugger, and seltees, small vessels of one mast.

The southern extremity of Italy is contiguous to Sicily; between them being the well-known Scylla and Charybdis. Scylla is considered in these days as an ordinary rock, but Charybdis is a vortex which might, on occasions, prove dangerous to a small vessel. The coasting trade is carried on in small Italian vessels.

The Gulf of Lyons, like all the gulfs on the north shores of the Mediterranean, is subject to violent gales from the northward, which sometimes last three days.

The islands of Sardinia and Corsica, lying north and south, extend over 80 leagues of the sea between Genoa and Tunis. The small island of Malta is, from its situation in the narrow sea between Sicily and Africa, and its excellent harbour, the great naval station of the Mediterranean, and second only in importance to Gibraltar.

The east coast of Spain presents numerous harbours, and is particularly adapted to navigation by steam vessels. The Balearic Islands, Majorca, Minorca, with Iviza, are adjacent to the Spanish coast. Gibraltar, standing at the foot of a rocky mountain 1430 feet high, is a place of extraordinary strength. From its situation, and the narrowness of the straits dividing Spain from Africa, which are only 11 miles across, Gibraltar is the key of the Mediterranean. A constant current sets through

the Straits of Gibraltar from the Atlantic at the rate of 2 or 3 miles an hour, and is felt as far as Cabo de Gata in Spain, 150 miles distant. Dr. Halley supposed this current required to supply the loss by evaporation, considering that the rivers which flow into this sea were not sufficient for the purpose.

Ceuta, opposite Gibraltar, is a strong fortress. The African shore from this place to Tripoli is hilly, and in some places sandy and sterile. On the low shelving shores of parts of these coasts the strong northerly winds do not blow home, and accordingly a ship may bear up on a lee shore and anchor in smooth water. Proceeding towards Barca, the ancient Ptolemais, we pass the Gulf of Sydra, or Greater Syrtis, an object of so much dread to the ancient seamen on account of marshes and sea-monsters. Admiral Smyth, who examined this coast, found that these terrors were poetical exaggerations of the difficulties of navigating a low and dangerous bight. Passing the desert shores of Libya, we arrive at Alexandria, founded on a sandy neck of land; and on the low and fertile shores of the delta at the mouth of the Nile, the ports of Rosetta and Damietta.

The navigation of the Mediterranean dates from a period of great antiquity. The story of Minos destroying pirates (Thucyd., i. 4) takes for granted the fact, that there must have been merchant vessels carrying something worth stealing from the earliest recorded period. That the Phœnicians and the Carthaginians navigated the Mediterranean at a very early date is quite certain. Strabo, who described this sea in the first century of the Christian era, describes the Mediterranean as being divided into three basins: the first lying between the Columns of Hercules and Sicily; the second, between Sicily and Rhodes; and the third, between Rhodes and the shores of Syria. His geographical positions, when tested by modern exactness, are found to be frequently wide of the truth.

This sea is navigated by vessels of no great size. There is a form of rig peculiar to the larger vessels, called *polacca*, which has originated in the suddenness and frequency of squalls, that often require the sail to be instantly taken in; for this purpose the masts are made in one piece, and the topsails, on being lowered, can slide down without interruption. The gales, though frequent and violent, never last long. The winds have been remarked as peculiarly variable in the Mediterranean, and three or four vessels have often been seen carrying different winds at the same time. The sirocco, or south-east wind, has always been noted for its depressing effects upon the animal system. Water-spouts are very common. Fish abound, especially the tunny, anchovy, and sardine; coral, sponge, and ambergris are found in large quantities.

The depth of the Mediterranean is without doubt very great, the sea being in most places unfathomable. Though poetically termed a 'tideless sea,' it is not strictly so; since in its latitudinal extent between Venice and the Lesser Syrtis it experiences a rise and fall of from five to seven feet; and there are slight tides in other places. Currents are numerous and strong. (Admiral Smyth's *Monograph on the Mediterranean*.)

MEDJIDIE, ORDER OF, instituted by the Sultan of Turkey in 1852, and conferred on many British

officers after the Crimean war. The decoration is a silver sun of seven triple rays, with the device of the crescent and star alternating with the rays. In the centre is the inscription 'Zeal, honour, and loyalty' in Turkish, and the date 1268, being the Mohammedan year corresponding to 1852. Inside the inscription is the sultan's name on a gold field. The order has five classes, and the badge differs in size for each class. A star of similar design to the medal is worn on the left breast by the first class, and on the right breast by the second class.

MEDLAR. [FRUIT.]

MEDOC. [GIRONDE.]

MEDULLA of Plants, the name given by older botanists to the pith of dicotyledonous plants, from a supposed resemblance to the spinal marrow (*Medula spinalis*) of animals. The *medullary rays* are the processes of cellular tissue stretching out from the pith. These rays become much compressed during growth. The *medullary sheath* is the ring or tube which surrounds the pith, composed chiefly of sap ducts. In monocotyledonous plants there is no proper distinction between the wood and the pith.

MEDUSA, in classical mythology, one of the three Gorgons. She had been celebrated for her personal charms and the beauty of her locks; but Minerva, in revenge for a violation of the sanctity of her temple, turned her locks into serpents, which had the power of petrifying those on whom she looked. She was killed by Perseus, who placed her head upon the ægis of Minerva, which he had used in his expedition, and it retained its petrifying power as before.

MEDUSA (Zoology), the Linnaean name for a genus of simple or free *Acalephæ*, vulgarly known to the British by the name of *Sea-blubbers* or *Sea-nettles*, extremely transparent, difficult to observe in their native element, and still more difficult to preserve, from their gelatinous and easily decomposed texture. These beautiful but evanescent animals are very numerous, swarming on many of our coasts and in our estuaries, and occurring in almost all latitudes. [ACALEPHÆ.]

MEDWAY. [KENT.]

MEERSCHAUM means, in German, *sea-foam*, and the equivalent French name of *écume de mer* is applied to the same substance. It is a silicated magnesian mineral, found in Greece, Turkey, and a few other countries, and is used by the Tartars for washing linen, somewhat in the same manner as pearl ash or fuller's earth. The mineral is principally used, however, as a material for tobacco-pipes, which, when made, are soaked in melted tallow, then in white wax, and finally polished with shave grass. If genuine, a meerschaum pipe acquires a beautiful dark brown colour after being smoked for some time, the oil of the tobacco being absorbed by the clay; and this is a point to which connoisseurs in smoking attach much importance.

MEERUT, a town and district of British India, in the north-west provinces. The town is situated in lat. $28^{\circ} 59' N.$, long. $77^{\circ} 46' E.$, 930 miles from Calcutta, and has 29,000 inhabitants. Here, on the 10th May, 1857, occurred a serious mutiny and massacre—all the officers of the native troops being shot, and the whole of the European inhabitants massacred, without respect to age or sex—after

which the rebel sepoys marched to Delhi, and, proclaiming the old pensioned Mogul emperor of India, inaugurated the sanguinary rebellion of that year. Meerut has a handsome English church, and was inclosed by walls, which, however, are now decayed. There is a military cantonment two miles to the north, and the town is the head-quarters of the Bengal artillery. The district of the same name extends from lat. $28^{\circ} 33'$ to $29^{\circ} 17' N.$, and from long. $77^{\circ} 12'$ to $78^{\circ} 15' E.$ The area is 2332 square miles, and the population about 1,200,000. The principal rivers are the Ganges (which forms the eastern and western boundary) and the Jumna, which supplies water for the Feroz Shah and Doab canals. The Ganges Canal also runs through the centre. The soil is fertile, fruits and sugar-cane being the chief products. The climate is healthy, with a minimum temperature of 32° , and a maximum of 102° Fahr.

MEGALICHTHYS (literally 'Great Fish'), in Geology, a large lizard-like fish of the carboniferous period. It occurs chiefly in the older beds of the coal measures, and is noted for its smooth, enamelled, lozenge-shaped scales, and comparatively small teeth. In the structure of its teeth, the Megalichthys bore great resemblance to those of a related form, the *Lepidosteus osseus*, which is still to be met with in some of the river swamps of North America. They were characterized by a hollow internal conical cavity, external flutings towards the base, and by growth from the bony substance of the jaw. The remains of the Megalichthys were first found at Burdiehouse, in the neighbourhood of Edinburgh. They have since been met with in different parts of the English coal field.

MEGALOSAURUS (Gr. *μεγας*, 'great,' and *σαυρος*, 'a lizard'), the name assigned by Dr. Buckland and the Rev. W. Conybeare to an extinct genus of Saurians found in the oolitic slate at Stonesfield, near Woodstock, and other localities. Huge fragments have been discovered in the ferruginous sandstone of Tilgate Forest in Sussex; and on the Continent in the oolite of Normandy; in the marble of Caen; and on the Jura, near Solothurn, according to H. Von Meyer.

Though no entire skeleton has yet been discovered, the number of bones and teeth collected give sufficient data to enable the observer to pronounce upon the general osseous structure, with almost as great a certainty as would be the result of the examination of the bones of the animal in a perfect and connected state.

The femur, or thigh-bone, and tibia, or leg-bone, are nearly three feet in length severally, so that the entire hind leg must have been nearly two yards long, and the discovery of a metatarsal bone measuring thirteen inches indicates that the foot was of a corresponding length. From these and other remains, including the vertebrae, teeth, &c., the size of this gigantic saurian has been calculated and its habits ascertained. The individual whose enormous thigh-bone (now in the British Museum) was obtained from the sandstone of Tilgate Forest, must have equalled the largest elephant in stature, and have measured from sixty to seventy feet in length.

That this gigantic lizard was carnivorous, the structure of its teeth sufficiently declares; and the

internal structure of the cylindrical and other bones shows that it was a terrestrial animal, though it may have occasionally taken to the water in pursuit of prey, such as Plesiosaurs and fishes. Its ordinary food is supposed to have been the smaller reptiles, crocodiles, and tortoises, whose remains occur abundantly in the strata where those of *Megalosaurus* abound.

MEGAPODIDÆ (Gould). 'The genera *Talegalla*, *Leipoa*, and *Megapodius*, form part of a great family of birds inhabiting Australia, New Guinea, Celebes, and the Philippine Islands. Their habits and economy are most singular, and differ from those of every other group of birds which now exists upon the surface of our globe. In their structure they are most nearly allied to the *Gallinaceæ*, while in some of their actions and mode of flight, they much resemble the *Rallidæ*; the small size of their brain, coupled with the extraordinary means employed for the incubation of their eggs, indicates an extremely low degree of organization.

'The three species of the family inhabiting Australia, although referable to three distinct genera, have many habits in common, particularly in their mode of nidification, each and all depositing their eggs in mounds of earth and leaves, which becoming heated, either by the fermentation of the vegetable matter or the sun's rays, form a kind of natural hatching apparatus, from which the young at length emerge fully feathered, and capable of sustaining life by their own unaided efforts.' (Gould, in Introduction to the 'Birds of Australia.')

MEGARIS, one of the political divisions of ancient Greece, was separated from Boeotia by the range of Mount Cithæron, and from Attica by the high land which descends from the north-west boundary of Attica, and terminates on the west side of the bay of Eleusis in two summits, formerly called Kerata, or the Horns, and now Kandili. Megaris was divided from the Corinthian territory on the west by the Oneian range of mountains, through which there were only two roads from the territory of Corinth into Megaris.

Megaris is a rugged and mountainous country, and contains only one plain of small extent, in which the capital, Mégara, was situated. The area was probably about 700 square miles. The rocks are chiefly calcareous. The country is deficient in springs.

Mégara was built on two hills, and connected with the port of Nisæa by two walls, built by the Athenians when they had possession of Mégara, B.C. 461-445.

Megaris in early times belonged to Attica, but it was taken from the Athenians by the Dorians, and a Corinthian colony was settled at Mégara. It remained for some time subject to Corinth; but afterwards asserted its independence. Mégara planted many colonies, of which the most important were Selymbria, Chalcédon, and Byzantium, on the Bosphorus and the Propontis, and Hyblæan Megara in Sicily. The history of this little state is inseparable from the general history of Greece.

MEGATHERIUM (Gr. *μεγας*, 'great,' and *θειον*, 'a bone'), the *Megatherioids* of Owen, who includes under this family the following genera of extinct Edentata:—*Megatherium*, *Megalonyx*, *Glossotherium*, *Mylodon*, *Scelidotherium*, and others.

It is in South America only that the remains of these

massive animals have been found; and we may add, it is only within the present century that the number of relics collected by enterprising travellers has enabled the philosophic anatomist to correct some errors, and to throw a new light upon the former history of the class Edentata. For a long time, the museum of Madrid afforded the only relics of the *Megatherium* in Europe; they were found on the banks of the river Luxan, south-west of Buenos Ayres, and sent over in 1789; but the skeleton they compose is deficient in several of its parts. Nevertheless Cuvier was enabled to determine with wonderful accuracy the affinities of this extinct giant of the Edentata.

The acquisition, some years ago, of a great portion of the bones of one of these animals by the Royal College of Surgeons, London, tended to supply the deficiency of our information on many points which still remained obscure. These remains were discovered in the bed of the river Salado, which flows through the pampas a short distance south from the city of Buenos Ayres, during an unusually dry period of three years, and presented by Don Hilario Soza, the owner of the property on which they were found, to Sir Woodbine Parish, who liberally transmitted them to the college, with other remains collected in the same locality. Among these remains were portions of an immense armadillo-like shell or crust, of osseous structure, consisting of rosettes united by sutures.

With such materials before him, Mr. Clift applied himself to the drawing up of a paper, entitled 'Some account of the remains of the *Megatherium* sent to England from Buenos Ayres by Woodbine Parish, jun., Esq., F.G.S., F.R.S., by William Clift, Esq., F.G.S., F.R.S.'

It was natural for Mr. Clift to suppose that the portions of dense tessellated armour found with the relics in question once formed the covering of this ponderous beast, and in this opinion Dr. Buckland and other scientific men coincided. It has, however, been since demonstrated by Professor Owen that this tessellated armour does not belong to the *Megatherium*, but to a large armadillo-like animal, to which the professor has assigned the name of *Glyptodon*, and whose hind feet, like the fore feet, appear to be so modified as to form the bases of columnar limbs destined to support an enormous incumbent weight. Moreover, from a rigorous examination of the details of the skeleton of the *Megatherium*, he proves the incompatibility of such a shield with its osseous structure.

The *Megatherium* must have been a most extraordinary animal. With the head and shoulders of a sloth, it combined in its legs and feet an admixture of the characters of the ant-eater and the armadillo. Its haunches were more than 5 feet wide, and its body 14 feet long and more than 8 feet high; its tail was massive and broad; its feet were a yard in length, and terminated by most gigantic claws. Heavily constructed, its movements were slow; it could neither run nor leap; but it could tear up the earth from the roots of trees, and then raised up on a tripod, composed of the hinder limbs and tail, wrestle with the trees of the forest, tear them down, and thus gain access to their leaves and tender shoots or branches.

The following comparative admeasurements, furnished by Mr. Clift, are in Sir Woodbine Parish's work, entitled 'Buenos Ayres and the Provinces of the Rio de la Plata:—

	Elephant. ft. in.	Megatherium. ft. in.
Expansion of the ossa ilia, . . .	3 8	5 1
Breadth of the largest caudal vertebra, ...	0 7	1 9
Circumference of middle of femur, ...	1 0	2 2
Length of the os calcis, . . .	0 7½	1 5

'The collection of fossils,' says Professor Owen, 'brought to England from South America by Mr. Darwin, has enabled me to add the following facts to the history of the Megatherium. Its teeth, for example, do not differ in number from those of the sloths, there being five on each side of the upper jaw. Microscopic examination having demonstrated a marked difference in the intimate structure of the teeth of the sloths and armadillos, I have ascertained by this mode of investigation that the teeth of the Megatherium have the same texture and composition as those of the sloth. And if, from identity of dental structure in two different animals we may predicate a similarity in their food, a glance at the bony framework of the Megatherium is sufficient to show that it must have resorted to other means of obtaining its leafy provender than that of climbing for it, whereby the necessity of inferring a proportionate magnitude of the trees which nourished the Megatherium is obviated.' (See Plate.)

In Professor Owen's admirable memoir on the *Mylodon* and other extinct gravigrade Edentata, the mode in which these animals struggled with the trees, and the peculiarities of their muscular forces, as well as of the nerves which supply the muscles, are depicted with graphic eloquence.

The Megatherium appears to have been furnished with a small proboscis as an adjunct to the tongue in stripping off the twigs and small branches of the prostrate trees; and as in the *Mylodon*, the two tables of the skull are widely separated by extensive cells.

With respect to the *Megalonyx*, it was obviously related to the Megatherium, but was of inferior size, not exceeding an ox in stature, though more solidly and heavily built. Its relics are apparently more rare than those of the Megatherium—they have been found in the cave of Lassa Grande, in Brazil, and also in the Big-bone Cave of Tennessee, U.S.

The genus *Gossotherium* (Owen) is founded on a fragment of a cranium in Mr. Darwin's collection, discovered in the bed of the same river in Banda Oriental in which the skull of the *Toxodon* was found. The fragment includes the parietes of the left side of the cerebral cavity, the corresponding nervous and vascular foramina, the left occipital condyle, a portion of the left zygomatic process, and the left articular surface of the lower jaw. No tooth nor locomotive extremity was present to lend its aid; and yet, upon the slender materials above stated, Professor Owen has been enabled to give generic distinction to the animal to which they belonged, and to fix its place in the animal series satisfactorily.

Allied to *Megatherium* is the genus *Mylodon* (Owen), of which three distinct species have been

described, viz. *M. Darwinii*, *M. Harlani*, and *M. robustus*, which far exceeds the others in size. An almost perfect skeleton of this last animal is preserved in the museum of the Royal College of Surgeons. Like the Megatherium it was formed for tearing down the trees of the forest, after having partially laid bare their roots. In stature it equalled a rhinoceros, but with bones infinitely more massive, muscles infinitely more voluminous and powerful. Its thick muscular tail conjoined to form with the hind limbs a firm tripod, which sustained the animal upright while, exerting its enormous strength, it swayed the tree to and fro, and at last pulled it down.

The gigantic and astonishing skeleton in question was discovered, as we are informed by Professor Owen, 'in the year 1841, by M. Pedro de Angelis, seven leagues north of the city of Buenos Ayres, in the fluviatile deposits constituting the extensive plain intersected by the great Rio Plata and its tributaries, and which has been raised during a recent geological epoch above the level of the sea.

'In this formation, and most probably anterior to its elevation, the animal must have been buried entire, for the parts of the skeleton were found little disturbed, and the very few bones that are wanting are such as would be likely to escape the search of the most diligent collector.

'About the same time, and near the same place, a tessellated osseous carapace of some large quadruped like an armadillo was exhumed, and information of this discovery having been communicated to the Royal College of Surgeons by Sir Woodbine Parish, late Her Majesty's Chargé d'Affaires at Buenos Ayres, both the carapace and the above-mentioned skeleton were purchased by the college.' This carapace is the shell of *Glyptodon clavipes* (Owen).

The *Scelidotherium* (Owen) was a large edentate quadruped, allied to *Megatherium* and *Orycteropus*. [AARD-VARK.]

The remains on which this genus is founded include the cranium, which is nearly entire, with the teeth, and part of the os hyoides; the seven vertical vertebrae, eight dorsal and five sacral vertebrae, both scapulae, the left humerus, radius and ulna, two carpal bones, and an ungual phalanx; the two femora, the proximal extremities of the left tibia and fibula, and the left astragalus.

These bones were discovered by Mr. Darwin at Punta Alta in Northern Patagonia, and in the same bed of partly consolidated gravel as that wherein the lower jaws of *Toxodon* and *Mylodon* were imbedded. All the parts were discovered in their natural relative position, indicating, as Mr. Darwin observes, that the sublittoral formation in which they had been originally deposited had been but little disturbed. This beach is covered at spring tides, and many portions of the skeleton were incrustated with *Fuustrea*: small marine shells were lodged within the crevices of the bones.

Sufficient of the cranium remains to indicate that its general form resembled an elongated, slender, subcompressed cone, beginning behind by a flattened vertical base which expanded slightly to the zygomatic region, and thence contracted gradually in all its dimensions to the anterior extremity.

MEGRIM (Fr. *migraine*, from Gr. *ἡμικρανία*), a severe intermittent pain affecting one side of the head.

MEHEMET ALI, Viceroy of Egypt, was born at Cavalla, in Roumelia, in 1769. He was one of the most remarkable men of the times in which he lived. In early life he was a humble tobaccoconist; but his tastes being more suited for a military career, he entered the army as a volunteer, and gained the favourable opinion of the governor of Cavalla by his success in suppressing the pirates of that island. In 1799 he headed a contingent of 300 Candian soldiers in an expedition to Egypt, where he co-operated with the British forces for the expulsion of the French. It was here that he laid the foundation of his military renown and his vast political ascendancy. In a short time he was enabled to seize the pachalic of Egypt, through the agency of the Mamelukes. In 1806 he was made Pacha of Cairo; and in the following year received the pachalic of Alexandria, as a reward for his services to the sultan of Turkey. But no sooner had he consolidated his authority, than he turned against his old confederates, the Mamelukes, 470 of whom were massacred in the citadel of Cairo, and 1200 in the country. After their destruction, Mehemet Ali had no difficulty in making himself master of Upper Egypt. He afterwards undertook the reduction of the Wahabies, and assisted the sultan, though unsuccessfully, in his attempts to subjugate the Greeks. About this time he reorganized his army on something like European principles, built a fleet, and erected fortresses and arsenals. His ambition, however, received a severe check by the destruction of his navy at Navarino in 1827. In 1830 he entered into a contest with the sultan for the possession of Syria, when the superiority of his disciplined army became manifest, and in 1832 he succeeded in carrying his victorious arms within a few days' march of Constantinople; but the contest was settled by the intervention of the European powers, though Syria was ceded to him on condition that he should acknowledge himself a vassal of the sultan. For seven years subsequently Mehemet Ali retained the uncontrolled dominion of Egypt, and continued to direct his energetic mind to the internal improvements of his newly-acquired kingdom. He found Egypt a sterile waste, and he left it a powerful country, enriched with commerce, and strengthened by ships and armies. He died at at Cairo on the 2nd August, 1849.

MEININGEN. [SAXE-MEININGEN.]

MEISSEN, a town in the kingdom of Saxony, situated about 16 miles N.W. from Dresden, on the left bank of the Elbe, over which there is a covered bridge, has numerous suburbs, and 10,500 inhabitants. The cathedral; the palace of Albrechtsburg, formerly the residence of the margraves of Meissen, in 1710 converted into a porcelain factory, employing 600 hands, who produce what is known as 'Dresden china'; and the former convent of St. Afa—are the chief buildings. The cathedral is the finest Gothic structure in Germany, and contains many monuments of very early times. There are also manufactures of hosiery, leather, colours, and camel's hair brushes, but the principal source of profit is the making of wine. The district was visited by a terrific flood in December, 1863.

MEISSENHEIM. [HESSE-HOMBURG.]

MEJERDA, or BA'GRADAS, is a river of Africa, which rises in the Great Atlas, and after a N.E.

course of 200 miles through Algeria and Tunis, enters the Mediterranean (Bay of Tunis), 24 miles N. of the city of that name. The Mejerda is not navigated, but it is used to irrigate the fields in the lower part of its course, where it flows through a wide and fertile valley. It overflows in the spring, and fertilizes the adjacent country.

MEKRAN. [PERSIA.]

MELADERMA (Gr. *μῆλας*, 'black,' and *δέρμα*, 'skin'), a genus of fishes of the family Zeidae, so called from the blackness of their skin.

The Greek word *melas*, or *mela*, 'black', is very frequently used as a prefix to compound words in zoology, mineralogy, and other departments of science; as *Melafusus*, 'black-spindled,' a genus of Mollusca, of the family Turbidæ, in which the shell is sub-fusiform, and the base contracted; *Melampus*, 'black-footed,' and *Melancantha*, 'black-spined,' each of them a genus of Mollusca, of the family Turbidæ; *Melania*, a genus of univalve fresh-water Mollusca, the shell of which has an epidermis, with a pointed spire; *Melaniame*, the Black Snails; *Melanite*, an opaque and velvet-black species of garnet, the constituents of which are silica, lime, oxide of iron, alumina, and oxide of manganese; *Melanella*, a genus of Mollusca, belonging to the Melaniana; *Melanochoite*, 'dark-coloured,' a mineral found in Siberia, of a deep orange-red or hyacinthine colour, with a resinous lustre, and nearly opaque, the specific gravity of which is 5.75; *Melantomia*, a genus of Mollusca, of the family Turbidæ, in which the shell is fusiform, and longitudinally ribbed; *Melasoma*, 'black-bodied,' a genus of birds belonging to the Dongo Shrikes, and of the family Laniadæ; also the name of a family of heteromorous Coleoptera, consisting of dark ash-coloured beetles, which are mostly apterous.

MELAIN, the colouring matter of the ink of the Cuttle-fish. It constitutes about three-fourths of the ink when dried by evaporation.

MELALEUCA, a genus of plants belonging to the natural order *Myrtaceæ*.

M. Cajuputi is the species which yields the chief part of the oil brought to Europe under the name of Cajeput oil. It is a native of Amboyna and other East India islands. The oil is obtained by distillation of the leaves and branches, which are collected the night before they are subjected to this process. It is very limpid, pellucid, and of a light or yellowish green colour. In its action on the human frame Cajeput oil participates in the properties of other volatile oils, and is rubefacient externally; stimulant, and antispasmodic, when taken internally.

M. leucodendron, the White Tree, or Cajeput Tree, is a native of the East India islands, and was at one time supposed to yield the oil of commerce. Roxburgh asserts that it possesses little or no fragrance in its leaves, and that it is seldom or never used for the distillation of the oil which is used in the European markets.

Upwards of thirty species of *Melaleuca* have been described, the majority of which are natives of New Holland. Many of them are fine plants with beautiful blossoms, and very desirable for the conservatory or greenhouse.

MELAMPYRUM, a genus of plants belonging to the natural order *Scrophulariaceæ*. Eight species

are enumerated by Don, six of which are European and two American. Of the six European, four are natives of Great Britain. *M. cristatum*, Crested Cow-wheat, is a native of woods and thickets in the eastern counties of England, and also generally of the north and middle of Europe. *M. arvense*, Purple Cow-wheat, is a native in fields of wheat in the south of Europe, and is found in Great Britain, though only rarely, in Norfolk and the Isle of Wight.

MELANCHTHON, PHILIP (or MELANTHON, as he himself was most accustomed to write the name), was born in the small town of Bretten, in the Palatinate of the Rhine, or Lower Palatinate, as it used to be called, the dominion of the elector palatine, on the 16th February, 1497. His father was George Schwartzerde, or Schwarzerdt. On the death of his father he was sent to the College of Pfortzheim, where he lodged in the house of a sister of the celebrated Greek scholar John Reuchlin, who was his relation; and it was from Reuchlin, who had translated his own Teutonic surname into the Greek formation Capnio, on the supposition of its connection with Rauch ('smoke'), that the young Schwartzerde (a compound, meaning, in English, 'black earth'), received the more melodious Grecized appellation of Melanchthon, by which alone he is now known.

After spending about two years at Pfortzheim, Melanchthon went to the University of Heidelberg, and thence to Tübingen, where he remained till, on the recommendation of his friend Reuchlin, he was in 1518 appointed, by the elector Frederic of Saxony, professor of Greek in the newly established university of Wittenberg. This situation he held as long as he lived. At Wittenberg Melanchthon became acquainted with Luther, then occupying the chair of theology in that university; and his name is immortally associated with that of Martin Luther in the history of the Reformation. The remainder of his biography is chiefly the detail of his various labours in the promotion of the doctrines of Protestantism. In 1519 he accompanied Luther to Leipzig, to hold a disputation on the divine origin of the papal authority, with Eckius, one of the ablest of the Catholic champions of that age. For some years after this he was actively employed, not only in writing books in defence of the reformed doctrines, but in founding schools and colleges, in visiting churches, and in other services of the same kind, undertaken at the command of the elector.

In 1530 he was appointed by the general body of the reformers to draw up what was intended to be the conciliatory confession, or exposition of their opinions, which was presented to the emperor at the Diet held at Augsburg in March that year. After the death of Luther, Melanchthon became involved in a bitter controversy with the more ardent spirits of his party, in consequence of his aversion to extreme courses, and especially the timidity he was accused of showing in his approval of the system of compromise between the two religions issued by the emperor in 1548, and afterwards known by the name of the Interim, an approval in which he stood nearly alone among the distinguished men of both sides. He died at Wittenberg, 19th April, 1560, leaving two sons and two daughters by his wife, the daughter of a burgo-master of that town, whom he had married in 1520. His death was in unison with the peaceful

tenor of his life. After having received some cordials, he was asked if he would have anything else; he replied, *Aliud nihil nisi Cælum*, 'Nothing else but Heaven.' His numerous works, consisting of theological treatises, commentaries on several of the Greek and Latin classics, Latin poems, and some historical and philosophical writings, were published in a collected form in five vols. folio, at Basle, in 1544, and in four vols. folio, at Wittenberg, in 1564, again in 1580, and again in 1601. A new and comprehensive German edition has recently been issued. His life was written by Wohllaart in 1860.

MELANORRHÆA, a genus of the natural family of *Terebinthaceæ*, tribe *Anacardiaceæ*. *Melanorrhæa usitata* is familiarly known as the Birmanese Varnish Tree. The tribe to which it belongs abounds in plants yielding a blackish, acrid, and resinous juice, used for varnishing and similar purposes, as the Marking Nut and the Japan Varnish Tree.

The Varnish Tree, or Theetsee, forms a large tree, with the habit of *Semecarpus*, and abounds in every part with a viscid ferruginous juice, which quickly becomes black by the contact of the atmosphere. The varnish is collected by inserting pointed joints of bamboo, which are closed at the other end, into wounds made in the trunk and principal boughs. The joints of bamboo are removed after from twenty-four to forty-eight hours, and their contents, which rarely exceed a quarter of an ounce, emptied into a basket made of bamboo and rattan previously varnished over. In Burmah, almost every article of household furniture intended to contain either solid or liquid food is lacquered by means of this varnish. It is also much employed in the process of gilding: the surface, being first besmeared with this varnish, has then the gold leaf immediately applied to it. The beautiful Pali writing of the Birmanese on ivory, palm-leaves, or metal, is entirely done with this varnish in its native and pure state.

MELANOSPERMÆE (Gr. 'black seed'), an important class of the *Algæ*, consisting of olive-green coloured plants, and including the following orders:—*Fucaceæ*, *Sporoclinaceæ*, *Dictyotaceæ*, *Chordoriaceæ*, and *Ectocarpaceæ*.

MELANTHACEÆ, are a natural order of poisonous Endogens, very nearly related to *Liliaceæ*. The most important species of the order are medical plants, viz., *Colchicum*, or Meadow Saffron, which is employed as a remedy for gout and rheumatism; *Veratrum album*, whose acrid poisonous rhizoma is White Hellebore; *Asagrua officinalis* and *Veratrum sabadilla*, both of which furnish the seeds called Sabadilla, now largely consumed in the preparation of Veratria; and a few North American plants of less moment.

MELASMA, a disease incident to old age, in which a black spot appears upon the skin, and develops into a painful ulcer.

MELASSES or MOLASSES. [MOLASSES.]

MELASTOMA, a genus of plants, the type of the natural order *Melastomaceæ*. The species of this genus are shrubs. The flowers are large, white, rose-coloured, or purple. *M. Malabathricum*, Malabar Melastoma, is a native of the East Indies, and frequent in the Indian Archipelago. The leaves of this plant are employed by the natives as a remedy in diarrhœa, dysentery, and mucous discharges.

MELASTOMACEÆ, an extensive natural order of polypetalous Exogens, nearly related to *Myrtaceæ*. The species are extremely numerous in tropical countries, where they usually form bushes or small trees, and are scarcely known beyond the tropics, with the exception of some *Rhexias*, which straggle into North America. In Europe the order is unknown, unless in gardens, where many species are cultivated for the sake of their gay purple or white flowers.

MELBOURNE, the capital of the colony of Victoria, Australia, is situated in lat. 37° 48' S., long. 144° 57' E., on the Yarra-Yarra river, 8 miles from its mouth, at the head of Port Philip. The river has a bar at its mouth, and a second about half-way to the town, so that the larger ships have to anchor at Hobson's Bay, near the entrance of the harbour. Formerly their cargoes were all discharged by river lighters; but there is now a railway direct from Melbourne, projecting into deep water on the E., and a second line from the W. side of the harbour. The city is commercially the most important in the Southern Hemisphere. The town was officially founded and named from the then English prime minister in 1837, but the site had been selected and occupied two years previously. Population (1851), 23,143; (1861), 108,242, including contiguous suburbs: it was estimated at 150,000 in 1865. The commerce of Melbourne has increased to a very great extent since the date of the gold discoveries in 1851, and now represents about nine-tenths of the entire trade of the colony. The exports and imports are each valued at from 12,000,000*l.* to 15,000,000*l.* annually, about two-thirds of the exports being gold.

The town is chiefly laid out on the right bank of the Yarra, which is crossed by a stone bridge. Its streets are straight, regular, and wide, and are paved and macadamized. Collins Street, the principal thoroughfare, is one-third wider than the famous Broadway at New York. It has been a municipality since 1843, with a 10*l.* franchise; the mayor and aldermen being elected by the council. South Melbourne and several other wards have established separate municipalities. The water supply is obtained from the head of the Plenty river, and it is conveyed a distance of 18 miles in iron pipes. The town was first lighted with gas in 1856, and now has steam, railway, and telegraph communication with the chief towns of Australia. A submarine cable to Tasmania was laid in 1859.

Melbourne has a public library, several handsome churches and chapels, mechanics' institute, hospital, benevolent and orphan asylums, Scotch college, an endowed university, with an annual income of 10,000*l.*, and a parliament house, finished in 1864, at a cost of 400,000*l.*; a custom-house, post-office in the Italian style, several banks and theatres, and Cremorne gardens; barracks, and a botanic garden. There is now a great extent of wharf accommodation, and a patent slip at Williamstown. The chief industrial establishments of Melbourne are flour-mills, tallow-boiling works, and brass and iron foundries. There are three daily and several weekly newspapers.

The shortest sea voyage to Liverpool (*via* Cape Horn), is 12,820 miles; average sailing voyage, eighty-five days; to Calcutta, 5230 miles; sailing voyage, forty-five days. The mean temperature of the year at Melbourne is 57°; in summer, 66°; in

winter, 49° Fahr. St. Kilda and Brighton are marine appendages of the capital, on the shore of Port Philip, visited for sea air, bathing, and occasional recreation.

MELBOURNE, WILLIAM LAMB, VISCOUNT, was born March 15, 1779. His father, Peniston Lamb, of Brocket Hall, Hertfordshire, was raised to the peerage of Ireland in 1770, by the title of Lord Melbourne, baron of Kilmore, created an Irish viscount in 1781, and finally elevated to the peerage of the United Kingdom in 1815, as Baron Melbourne, in the county of Derby.

The subject of this notice entered as a student at Lincoln's Inn, July 21, 1797, and was called to the bar November 23, 1804. In 1805 he married Lady Caroline Ponsonby (daughter of the earl of Bessborough), from whom he was afterwards separated. As Lady Caroline Lamb, she was well known for her literary talents. In the same year the Hon. William Lamb entered Parliament as member for Leominster, and joined the Whig party, then headed by Fox.

During the long and chequered administration of Perceval and Liverpool, Mr. Lamb continued in a course of moderate opposition, occasionally supporting the measures of government. He sat in Parliament for several different places; during the latter part of the time for the county of Hertford. On the accession of Canning to office (1827) he was made secretary for Ireland. Under Lord Goderich's public administration Mr. Lamb retained his office, and continued to serve with that of the duke of Wellington, until the resignation of Mr. Huskisson, in 1828, induced him also to resign. The death of his father, a few weeks afterwards, occasioned his removal to the House of Lords.

The prominent portion of Lord Melbourne's career commenced in 1830 with the Grey administration, when his lordship was appointed secretary of state for the home department. In this position he displayed a power of mind and a firmness of character which surprised the public, and acquired a reputation for political sagacity which marked him out for higher offices in the state. He was recognized as the leader of the Whig party in the upper house, and on Earl Grey's resignation of the premiership in July, 1834, was appointed his successor. He accordingly constructed an administration, but failed to secure the confidence of the sovereign.

In the following November the death of Earl Spencer, father of the then Lord Althorp, caused the removal of his lordship to the House of Peers, and he resigned the office of chancellor of the exchequer. The king intimated to Lord Melbourne that he considered the retirement of Lord Althorp as equivalent to a breaking up of the ministry. There was, therefore, but one course to pursue, and the duke of Wellington and Sir Robert Peel immediately came into power.

On the meeting of the new Parliament in February, 1835, Lord Melbourne in the upper house, moved an amendment to the address, in which he made their lordships express a hope that his Majesty's councils would be conducted in a spirit of well considered reform; and to lament the dissolution of the late Parliament, as having interrupted and endangered the vigorous prosecution of measures to which the wishes of the people were directed. The proposed

amendment, however, was eventually withdrawn. After a few months of adverse votes, the Irish tithe question drove the ministry from office, and Lord Melbourne was reinstated as first lord of the Treasury. The new premier lost no time in forming a decidedly liberal cabinet; and from April, 1835, to September, 1841, the Whig government effected some very beneficial reforms.

Not the least service which Lord Melbourne at this time rendered to his country was the political education of Queen Victoria, whom he trained to perform the responsible duties of her high position with a wisdom and an impartiality that won the 'golden opinions' of men of all parties. In 1841, having no longer a majority in the Commons, the premier retired from office; in the following year he was seized with a partial attack of paralysis, the result of over-exertion of the brain; but he recovered to a great extent, and for several years enjoyed a dignified and lettered ease. He died at his family seat, Broomfield Hall, 24th of November, 1848, in the seventieth year of his age. Lord Melbourne possessed a cultivated and lucid intellect, a cool, courageous temperament, a mind free from prejudice, a large share of common sense, and a highly honourable, frank, and chivalrous disposition. His grace of manner fitted him to shine in social circles, while his wide and liberal scholarship endeared him to men of letters.

MELCOMBE REGIS. [DORSETSHIRE.]

MELDRUM, OLD. [ABERDEENSHIRE.]

MELFI. [BASILICATA.]

MELIA, a genus of plants belonging to the natural family *Meliaceae*, to which it has given its name. The species are few, and chiefly Indian; one is naturalized in the south of Europe, and one is found in North America. *Melia azadirachta* is bitter, and considered a valuable tonic. *Melia azedarach*, the Pride of India, or Common Bread-tree, is a native of China and the north of India. It is much cultivated in the southern United States of North America. Its flowers resemble those of the lilac, and are very fragrant.

MELIACEÆ, a natural order of polypetalous Exogens, consisting of trees or shrubs, inhabiting all countries within the tropics, but very rare in colder climates; the *Melia azedarach*, or Bread-tree, a Syrian plant, now naturalized in the south of Europe, forming the principal exception. In general the species are bitter and astringent, but they are sometimes dangerously poisonous, acting violently as emetics and purgatives. The Cape Ash (*Esebergia Copensis*) and the Neim or Margosa Tree (*Azadirachta Indica*), belong to this order.

MELICA, a genus of plants belonging to the family of Grasses. There are two British species of this genus, *M. uniflora* and *M. nutans*, which are found in damp shady woods. *M. alissima*, a Liberian species, grows to the height of 3 or 4 feet.

MELILOTUS, a genus of plants belonging to the natural order *Leguminosæ*. None of the species are ornamental plants, and they are seldom cultivated except in botanical collections. Two species are found native in Great Britain. *M. officinalis* has long roots, and a branching stem two or three feet high. It grows wild in woods, hedges, and neglected fields. When cultivated in a dry soil and made into

hay, it has a powerful aromatic smell, and mixed in a small proportion with meadow-hay, gives it an agreeable flavour. *M. vulgaris* is a rare plant, and is found in sandy and gravelly places near the sea.

MELIPHA/GIDÆ ('Honey-eaters'), a family of Tenuirostral birds, described by Vigors, as 'that extraordinary group, the existence of the much more considerable portion of which was unknown to the Swedish naturalist, for which there was consequently no place in his system, occupies a prominent and important situation in the ornithological department of nature. Chiefly confined to Australasia, where they abound in every variety of form, and in an apparently inexhaustible multitude of species, they find a sufficient and never-failing support in the luxuriant vegetation of that country. There the fields are never without blossom, and some different species of plants, particularly the species of *Eucalyptus*, afford a constant succession of that food which is suited to the tabular and brush-like structure of the tongue in these birds. Their numbers and variety seem in consequence to be almost unlimited.'

Mr. Gould, in his splendid work on the 'Birds of Australia,' figures and describes fifty-eight species, exclusive of some few which are found in New Guinea and some of the Polynesian Islands. Mr. Gould admits the following genera: *Meliphaga*, *Glyciphila*, *Ptilotis*, *Plectorhyncha*, *Xanthomyza*, *Melicophila*, *Entomophila*, *Acanthogenys*, *Anthochara*, *Tropidorhynchus*, *Acanthorhynchus*, *Myzomela*, *Entomyza*, *Melithreptus*, and *Myzantha*. [TENUIROSTRES.]

MELISSA, a genus of plants belonging to the natural order *Labiata* or *Lamiaceæ*. In its recent state it has a rough aromatic taste and a pleasant lemon-like smell. It is frequently used in infusion, under the name of Balm Tea, as a common drink in fevers. It was one of the medicines recommended by Paracelsus, but at the present day it is only used as a popular remedy.

MELKSHAM. [WILTS.]

MELLITE (Gr. *μῆλι*, 'honey'), a mineral of a honey colour, found in Thuringia, and generally known as Honey-stone. It occurs nodular, granular, and crystallized. The crystals are translucent, and of a honey yellow colour. It is something like amber, but distinguished from it by its weak electricity and double refraction. Its specific gravity is 1.60, and its constituents are mellitic acid, alumina, and water.

Mellitic Acid has a sour bitter taste, is very soluble in water, and also in alcohol, and it crystallizes in colourless needle-form crystals. It consists of O⁴ H¹ C⁴.

MELLON, a compound which, like cyanogen, consisting of the same elements in different proportions, is considered as a compound radical. Mellon has a yellow colour; is insoluble in water, alcohol, dilute hydrochloric or sulphuric acids. By particular treatment there may be produced from it *hydromellonic acid*, a dirty white gelatinous substance, which becomes yellow on drying. Mellon consists of N⁴ C⁶, and this, with H¹, gives hydromellonic acid.

MELODRAMA (Gr. *melos*, 'a song,' and *drama*), a kind of dramatic performance in which music or singing is intermixed. It is, strictly speaking, a musical drama; but in France and England the name

has been extended to sensational plays of a serious nature, which are unworthy of the name of tragedy. Of these 'The Green Bushes' and 'The Colleen Bawn' may be named as favourable specimens. Operas were at first called 'melodramas,' and the word still retains its proper signification in Germany.

MELODY (Gr. *μελωδία*), a musical term for the disposition of sounds for a single voice or instrument in regular order, and in such a relation as to produce an agreeable effect upon the ear. The melody of a piece is sometimes called its air or motive.

MELÖE. The Linnæan genus *Meloe* included the several genera of heteromorous Coleoptera now forming the family *Cantharidae*, interesting on account of its including those beetles known under the name of 'blistering flies,' and employed in medicine. The term *meloe* is now restricted to the apterous *Cantharidae*, and the species are all beetles with large and swollen bodies, and short oval elytra, lapping over each other at the base of the suture. They are sluggish creatures, and feed on various plants, especially the species of *ranunculus*. When alarmed they emit from the articulations of their legs an oily yellow or reddish liquid.

MELOLONTIIDÆ, a family of coleopterous insects of the section *Lamellicornes*, and subsection *Phyllophagi*. This family, of which the common Cockchafer (*Melolontha vulgaris*) is an example, consists of three genera, *Melolontha*, *Rhizotrogus*, and *Serica*, and some sub-genera of minor importance. Species of this family are found in all parts of the world. In the genus *Melolontha* the antennæ are ten-jointed; the terminal five, six, or seven joints are lamellated, and form a large fan-like appendage; in the females the lamellated joints form a smaller club than in the males, owing to their smaller size, and also to a decrease in their number, there being six, five, or four; the labrum is deeply cleft on its lower margin; the claws of the tarsi are furnished with a spine on the under side near the base; the abdomen in the male sex often terminates in a horny pointed process.

Two species of this genus are found in England, the common Cockchafer (*Melolontha vulgaris*, Fab.), and the *Melolontha fulva*, a large species nearly an inch and a half in length, and which is of a blackish-brown colour, with irregular white markings. This beautiful insect is common in some parts of the Continent, but rare in this country, and has been found chiefly in the neighbourhood of Deal.

MELON (the *Cucumis melo* of botanists) is an herbaceous, succulent, climbing or trailing annual, cultivated for its fruit in hot eastern countries from time immemorial, but first introduced into England about 1570. Its original English name was *Musk Melon*. In regions where most cooling vegetables disappear on the approach of great summer heat and drought, the melon, together with the water-melon, become essential substitutes. The antiquity of the cultivation of melons being so remote, and their dispersion over large portions of Asia and Africa so extensive, their indigenous locality cannot be traced at the present day.

If the roots be favourably situated, so far as moisture is concerned, the melon will bear a tropical heat; and, generally speaking, it will not succeed

perfectly in the open air beyond the forty-third parallel of latitude. Its range of atmospheric temperature may be estimated at between 70° and 80°.

Light is so essential, that unless the plants are kept near the glass, no tolerable degree of flavour will be acquired. As much of the direct rays of the sun should be admitted as the plants will endure, more especially when the fruit is approaching maturity. A free admission of the air is also to be recommended, so far as is consistent with the maintenance of a high temperature. The regulation of moisture in the artificial atmosphere in which melons are grown under an English sky is, of all others, the greatest difficulty. Covering the soil with slates or tiles, or with clean gravel, has been successfully resorted to as a mode of preventing the air in the frame from being at all times saturated with moisture exhaled from the soil.

MELÖS. [MILÖ.]

MELPOMENE. [MUSES.]

MELROSE. [ROXBURGHSHIRE.]

MELTON MOWBRAY. [LEICESTERSHIRE.]

MELUN, the ancient *Melodunum*, capital of the French department of Seine-et-Marne, is situated on the Troyes Railway, 26 miles S.S.E. of Paris, and has 11,170 inhabitants, who manufacture woollen stuffs, printed calicoes, leather, bricks, tiles, and cement. This town was besieged and taken by the English in 1419. It is built on an island on both banks of the river Seine, the largest quarter standing on a slope on the right bank, and the three parts being united by two bridges. It is on the whole a well-built town; the banks of the river are lined with quays, and several new promenades have been formed. The church of St. Aspais, on the right bank of the Seine; the church of Notre-Dame, on the island; the monastery of St. Père, the Carmelite convent, now converted into a court-house, a prison, a guard-house, and theatre; the old monastery of La-Maison-des-Frères, and the central prison—are the chief structures in the town. Melun has a good trade in corn, flour, wool, and cattle.

MELVILLE, ANDREW, was born August 1, 1545. He was the youngest of nine sons, children of Richard Melville, of Baldory, near Montrose, in Scotland. At the age of fourteen, he was removed from the grammar-school of Montrose to St. Mary's College, in the University of St. Andrews. This place he left in 1564, with considerable reputation for his proficiency in philosophy and the languages, and repaired to the Continent. His philosophical acquirements obtained for him successively the place of regent in the college of St. Marceon, France, and the chair of humanity in the academy of Geneva, which place he reached on foot, and in a state of destitution. After a residence abroad of two years, he returned to England, and published his poetical paraphrase of the 'Song of Moses,' and a chapter of the Book of Job, in Latin.

Shortly after Melville's arrival in Edinburgh, in July, 1574, he was appointed by the General Assembly principal of Glasgow College. He introduced improvements in teaching and discipline of great importance, and infused an uncommon ardour into his pupils. It was not, however, as a mere scholar or academician that he was distinguished. He was active in the church courts and in the conferences

held with the Parliament and privy council on the then much agitated subject of church government. To him is generally ascribed the overthrow of episcopacy at that time and the establishment of presbyterianism, and he commonly went afterwards by the name of Episcopomastix, or the Scourge of bishops.

In the reformation and improvement of the universities Melville also took a leading part. At the end of the year 1580 he was translated from Glasgow to be principal of St. Mary's College in the University of St. Andrews, where he distinguished himself by his usual zeal and ability. In his scholastic labours he did not lose sight of the condition of the church, and being called on to open an extraordinary meeting of the General Assembly in 1582, he inveighed in strong terms against the arbitrary and oppressive measures of the court. For this he was cited before the privy council for high treason. The charge was not proved; but the privy council found him guilty of behaving irreverently before them, and sentenced him to imprisonment. Fearing his death was ultimately intended, he was urged by his friends to make his escape, and accordingly leaving Edinburgh he went to London, where he remained till about the end of 1585, when Arran having been driven from court, he returned to Scotland, and resumed his former station at St. Andrews. In May, 1606, after the king had ascended the English throne, Melville was desired by James to repair to London that he might consult him on ecclesiastical matters. Melville had various interviews with the king; but having written a Latin epigram, in which he expressed his feelings of indignation at some rites of the English church on the festival of St. Michael, he was summoned before the privy council, found guilty of *scandalum magnatum*, and imprisoned in various places until February 1611, a period of about four years, when, at the solicitation of the duke of Bouillon, who required his services as a professor in the University of Sedan, he was permitted to depart the kingdom. In 1620 his health, which had previously been slightly impaired, grew worse, and in the course of the year 1622 he died at Sedan. (*Life of Andrew Melville*, by Dr. McCrie.

MELVILLE ISLAND is situated on the northern coast of Australia, between 11° and 12° S. lat., and 130° 20' and 131° 34' E. long. Area, 1800 square miles. It is separated from Bathurst Island, which lies east of it, by Apsley Strait, 46 miles long by 3 broad. East of the island lies Coburg Peninsula, where a British colony was established some years ago [ESSINGTON, PORT], and between them lies Dundas Strait, 15 miles wide. The eastern end of Melville Island is only 15 miles from the mainland of Australia. The northern line of coast, and also the western, along Apsley Strait, where alligators abound, are low, intersected by swamps, and covered by impenetrable woods of mangroves. The interior is more elevated, and has an undulating surface. The island is well clothed with wood, and presents one mass of thick green foliage. Water is easily obtained by sinking wells. The natural vegetation is luxuriant, but the soil is not generally good for farming. There are several species of eucalyptus. The zoology of the island is very varied. The native inhabitants are of the Australian stock, but somewhat more intelligent.

ME'LYRIS, a genus of coleopterous insects established by Fabricius, for the reception of certain species of the Linnæan genera *Cantharis* and *Dermestes*. It belongs to the family *Serricornes* of Latreille, and constitutes the type of the family *Melyridæ*. The *Melyridæ* are active and often gaily coloured little beetles, usually found on flowers, which they frequent for the purpose of preying on other insects. The larvæ, as well as the perfect insects, are carnivorous. The family is intermediate between the *Telephoridæ* and *Cleridæ*.

MEMBRANE, a name given to different thin organs, representing a species of supple, more or less elastic webs, varying in their structure and vital properties, and intended in general to absorb or secrete certain fluids, and to separate, envelop, and form other organs. Membranes are either simple or compound. *Simple membranes* comprise three orders:—

1. *Mucous membrane* is so called on account of the mucous fluid by which it is constantly lubricated. Mucous membranes line the canals, cavities, and hollow organs, which communicate externally by different apertures on the skin. The mucous membranes have a striking analogy with the cutaneous tissue, in organization, functions, and diseases. They are composed of corium, papillæ, and epidermis, and are furnished with a multitude of follicles, which secrete a viscid humour—mucus. They receive a quantity of arterial vessels, veins, lymphatics, and nerves.

2. The *serous membranes* are thin, transparent, and composed of one lamina. One surface adheres to other textures; the other is smooth, polished, and moistened by a serous fluid. They are arranged in the form of sacs without apertures, as great intermediate reservoirs for the exhalant and absorbent systems, in which the serous fluid in passing from one system, carries some time before it enters the other. The serous membranes resemble the areolas membrane in structure and diseases. They facilitate the motion on each other of the organs which they envelop.

3. *Fibrous membranes*.—These are almost all continuous, and terminate at the periosteum, their common centre. They are not free or moistened by any particular fluid. They adhere by both surfaces to the adjoining parts; they are firm, resisting, but slightly elastic, and of a white colour, sometimes pearly and glistening. Their vessels are numerous in some, as in the dura mater and periosteum; in others, scarcely perceptible, as in the aponeuroses. The presence of nerves has never been proved, although several circumstances regarding their sensibility render their existence probable. The fibrous membranes serve in general to augment the solidity of the organs which they envelop, to retain the muscles in their respective positions, to favour the motions of the limbs and that of the muscles and skin, and to form canals and rings for the passage of different organs.

There are three species of *compound membranes*:—

1. The *sero-fibrous*, formed of a serous and fibrous lamina, intimately adherent to each other, as the pericardium and dura mater.

2. The *sero-mucous*, formed of a serous and mucous lamina, as the gall bladder at its lower part.

3. The *fibro-mucous*, consisting of the union of a fibrous and mucous membrane, as the mucous membrane of the nasal fossæ, gums, &c.

MEMECYLA'CEÆ are a very small natural order of polypetalous Exogens, consisting of a few tropical plants of little interest. Most of them inhabit the East Indies, the Isle of France, and Madagascar. No useful properties have been assigned to any of the species, except to *Memecylon edule*, an East Indian plant, whose leaves are an ingredient in the dyes of Coromandel, according to Roxburgh, and whose ripe, astringent, pulpy black berries are eaten by the natives.

MEMEL. [KÖNIGSBERG; NIEMEN.]

MEMLING, or MEMMELINCK, HANS, or JAN, was born probably about 1439, at or near Constanx. His principal works are—'St. Ursula and her Companions,' the 'Adoration of the Magi,' and the splendid altar-piece of the 'Marriage of St. Catherine.' There are pictures ascribed to Memling at the Hague, at Antwerp, at Louvain, at Berlin, and at Munich. The date of his death is uncertain, but it probably took place in Spain between 1499 and 1506.

MEMMI, SIMONE, or *Simone di Martino*, was a very celebrated Italian painter of the fourteenth century. He was born at Siena in 1284, or according to Vasari, in 1285. He was the rival of Giotto. Simone now owes his fame chiefly to Petrarch: they were both living at the same time at Avignon during the residence of the popes there, and Simone painted the portrait of the celebrated Madonna Laura for the poet, who rewarded him by writing two sonnets in his honour. Few of Memmi's works now remain, and these are dry and meagre performances. The principal are the frescoes of the chapel degli Spagnuoli at Florence.

MEMNON, in Greek mythology, a son of Eos, or the Morning, and Tithonos, or Titan, the Sun, but represented in the later legends as a son of Laomedon and brother of Priam, who took part in the Trojan war, and was slain by Achilles. His allegorical character, however, is shown by the tears of morning dew which his mother shed over his corpse, just as the big drops fell from the sky when Zeus bewailed the fate of his son Sarpedon. Memnon, at the request of Eos, was raised from Hades to Olympus.

The name Memnon would seem to be corrupted from *Mei-amun*, 'beloved of Ammon.' The Greeks applied it to a celebrated statue at Thebes in Upper Egypt, which at sunrise, either really emitted, or was fabled to emit, a musical sound like the voice of a harp. It is supposed to have been included in the gigantic pile of the Rhamesseion, so called from its reputed founder, Rhameses or Sesostris, whose immense ruins still attract the wondering notice of travellers.

MEMORY is a name given to one of what are called the faculties of the mind—the faculty of remembering or recollecting. The word is used to denote at the same time the operation or act of remembering and the state of the mind when it exercises the faculty, as distinguished from the faculty itself, but this last is a derived and by far the rarer use of the word.

When an idea is reproduced in the mind by any of the ordinary modes of association, and there co-exists with this idea the idea of its having been

before present in the mind, this complex state of mind is a case of memory. We are then said to remember the thing, the idea of which is thus present to the mind. This is an exercise of the faculty of memory.

There is a distinction between *remembering* and *recollecting*, which it is worth while to notice. The ideas that are remembered either come into the mind without any effort on the part of the person remembering, or with such effort. In the first case the person is more properly said to remember; in the second, to recollect. The effort of recollection may be generally described as consisting in seeking out for different ideas which are likely to recall, by any of the ordinary modes of association, the desired idea. What these modes of association are has already been explained in the article ASSOCIATION.

MEMPHIS. [TENNESSEE.]

MEMPHIS (the *Men Nefer* or 'Good Station' of the Egyptians, and the *Memf* of the Arabs), an ancient city of Egypt, once the rival of Thebes in magnitude and splendour, was situated on the western bank of the Nile, about 10 miles S. of Cairo, on the site of the present villages of Kaff-el-Tyat, Metrahenny, and Koum-el-Azyzeh. There are still considerable remains scattered over an extensive area, though it has for hundreds of years been used as a stone quarry by the successive conquerors of the country.

MEN'AGE, GILLES, was born at Angers, August 23, 1613. Ménage began life as an advocate at Paris; but finding this profession not to suit his taste, he became an abbé. He resided for a time in the family of Cardinal de Retz, but finally established himself in a house of his own in the cloister of Notre-Dame, which soon became celebrated for the assemblies of men of letters, whom he continued to gather around him every Wednesday evening to the end of his long life. Of his numerous works the following are the most important:—'*Origines de la Langue Française*;' '*Poemata Latina, Gallica, Græca, et Italica*;' '*Observations sur la Langue Française*;' '*Origini della Lingua Italiana*;' '*Anti-Baillet*;' a valuable edition of Diogenes Laertius, with annotations; and some other editions of classical and other works. After his death in 1692, his friends published, under the title of '*Ménagiana*,' a collection of his bon-mots and the more striking remarks he made in conversation.

MENAI STRAIT. This narrow channel, about 11 miles in length, which separates the island of Anglesey from the mainland of Wales, intervenes on the great mail route from England, by way of Holyhead, to the eastern coast of Ireland. It is crossed by a suspension bridge, of which the first stone was laid August 10, 1819, and the mail-coaches drove over it for the first time January 30, 1826. The Menai Bridge was planned and executed by Telford. The distance between the supporting pyramids or points of suspension is 560 feet, and the height of the carriage-way above high water in the strait is 100 feet. The roadway of the bridge is divided into two carriage-ways, each 12 feet wide, with a foot-path 4 feet wide between them. It is also spanned by a still more remarkable structure—the Britannia Bridge, built by Robert Stephenson, consisting of two tubes of iron placed side by side, through which the up and down trains of the Chester and Holyhead Railway respectively pass. The entire length of each

tube is 1513 feet, and the height above high water 102 feet. Each tube consists of four pieces, the ends of which rest on a central pier built on the Britannia Rock in the middle of the Menai Strait, two towers on the shores of Anglesey and Caernarvonshire respectively, and two abutments farther inland on each coast. There are therefore eight tubes in all. The clear length of each tube reaching from the side-towers to the central tower is 460 feet, so that the entire length of tube across the strait is 920 feet, leaving 593 feet for the entire length of the side tubes. The top of each tube forms a regular arch; the bottom is quite straight and horizontal. The interior height is 26 feet in the centre, and 18 feet 9 inches at the ends. The internal width is 14 feet from side to side. The tubes are formed of plates of wrought iron $\frac{3}{8}$ to $\frac{1}{2}$ inch thick, strongly riveted together. The weight of the whole structure is 10,540 tons, and its cost amounted to 601,865*l*. The first train crossed the strait on March 6, 1860. [HOLYHEAD.]

MENANDER, a Greek poet, one of the writers of the New Comedy, was born B.C. 341, and died, as some suppose, by drowning, B.C. 289 or 290. He wrote more than one hundred comedies, of which only fragments remain. His plays were probably very simple in the dramatic action. Terence, who professed to imitate him, did not adhere to this simplicity, but, as he tells us himself, added to the main plot a subordinate one taken from a different piece of Menander; thus, as he says, making one piece out of two.

MENDELSSOHN BARTHOLDY, FELIX, the illustrious musical composer, was born at Hamburg, February 3, 1809. The son of wealthy parents, he received a careful education, and his natural disposition for music was nurtured by his mother, who provided him with the best examples for study, and judiciously rewarded his youthful exertions. In 1812 the family removed to Berlin, where their home was the resort of the most eminent artists and men of letters. Here the young musician was placed under the tuition of Berger for the pianoforte, and Zelter for composition. His progress was extraordinary, and he made his first appearance in public in 1817, when he played Dussek's military concerto. In his twelfth year appeared his first published pianoforte Quartet, dedicated to Goethe, whom he had visited at Weimar, and from whose counsel and encouragement he derived peculiar benefit. In the spring of 1825 he visited Paris, and was introduced to Cherubini, who, recognizing both his present powers and future promise, warmly advised him to continue his musical studies. In this year was produced at Berlin his opera of 'Die Hochzeit des Camacho' (The Wedding of Camacho), which, despite some marks of immaturity, attests the wonderful freshness and originality of the composer's genius. About this date also he produced his overture to the *Midsummer Night's Dream*, 'Meere stille' (The Calm Sea), and his *Otteto* in E flat; three of the most wonderful works ever produced at so early an age. Not only are the melodies exquisite, but the highest art is perceptible in their arrangement and development, so that it may be said of Mendelssohn's genius, that, like some oriental flowers, it bloomed into full maturity without undergoing the ordinary process of growth.

The incidents of a musician's life are neither many nor striking, and those of Mendelssohn's may easily be recapitulated. He visited London in 1829, and at once secured a reputation. His *Symphony in C minor* was performed at the concerts of the Philharmonic Society, while his pianoforte-playing delighted the most critical and fastidious audiences. While in London he wrote his operetta of 'Heimkehr aus dem Fremde,' known in English as the 'Stranger and Son,'—as a love-offering on the occasion of the 'silver wedding' (the twenty-fifth anniversary) of his parents.

In 1830 he visited Italy, and among the glorious ruins of ancient Rome composed the 'Reformation Symphony,' and the 'Walpurgis Night.' Afterwards he repaired to Naples and Venice, and travelled through Switzerland, everywhere deriving inspiration for his versatile genius, which was keenly alive to the external influences of nature. We find him again in England in April, 1832, and 1833, producing on the former occasion, his *Concerto in G minor*, and overture to the 'Isles of Fingal;' on the latter, the 'Trumpet Overture,' and *Symphony in A minor*.

The death of his father, in November, 1835, was a severe shock to his affectionate nature, and the solemn impression which it produced may be traced in his magnificent oratorio of 'St. Paul.' Home joys were exceedingly dear to him, and his happiness was accordingly increased and confirmed by his marriage in the spring of 1837, to *Mlle. Cecilie Jean-Renaud*, of a good Frankfort family, a woman not unworthy of him.

Passing over some minor works which would have made the renown of any other composer, we must record the production of the 'Hymn of Praise,' in 1840, a composition of immeasurable beauty, replete with the choicest fancies and noblest thoughts; and the setting to exquisite music the lyrical portions of two of the tragedies of Sophocles. In 1842 he embodied his recollections of Scottish scenery in the wondrous *Symphony in A minor*, dedicated to Queen Victoria.

The music to the 'Midsummer Night's Dream;' the overture to 'Ruy Blas;' the matchless 'Songs without Words,' a species of musical composition which he may be said to have created; and above all, the sublime oratorio of 'Elijah,' first produced in London in 1846—were among his later and sublimer works. In 1844, in 1846, and again in 1847, he visited England. In the latter year it was evident that his health had given way under the pressure of incessant work and continual excitement, and the tidings of the sudden death of his favourite sister Fanny, produced a terrible effect on his shattered frame. He died at Leipzig, on the 4th of November, 1847.

It would be difficult to decide in which branch of his art this great composer displayed the most astonishing genius. He was the best contrapuntist since Mozart. Almost unrivalled as a melodist, his command over all the resources of harmony was supreme. In sacred and secular music he was alike distinguished by the fertility and originality of his ideas, which were never forced, but always charmed by their spontaneity. Nor was he only a musician, as a draughtsman he might have attained renown. He was well versed in the ancient classics, and spoke and wrote both English, Italian, and French; while

as a man his character was marked by honour, truthfulness, geniality, and affection.

MENDE. [LOZÈRE.]

MENDICANT ORDERS are certain religious associations in the Roman Catholic church, so called because they give up to the church all property, whether real or personal, which their members may have possessed, and subsist upon alms. They carry out the principle of religious poverty and self-abasement to the extreme. By a decree of the second council of Lyons in 1274, the mendicant orders were reduced to four—viz., Dominicans, Carmelites, FRANCISCANS, and AUGUSTINS, or Austin Friars. [FRIARS.]

MENDIP HILLS. [SOMERSETSHIRE.]

MENDOZA. [PLATA, LA.]

MENÉHOULDE, SAINTE. [MARNE.]

MENGES, ANTON RAFAEL, was born at Aussig in Bohemia, in 1728. He received a rigorous artistic education from his father, who was a painter. In 1741 his father quitted Dresden, whither he had been called by Augustus III. (for he was a native of Denmark), and went to Rome, taking young Menges with him, where he made him labour most assiduously in the Vatican, scarcely allowing him to take his meals. In 1744 he returned to Dresden, when Augustus appointed him court-painter, but he was permitted to revisit Rome and continue his studies for some time longer. He soon began to distinguish himself by his original compositions, among the rest by a Holy Family, in which the Virgin was painted from a beautiful peasant girl, of whom he had become so enamoured that he turned Catholic for her sake and married her. His reputation was greatly increased by the numerous works he executed for Charles III. of Spain. His pencil was employed in decorating the royal palaces of Spain; and the Apotheosis of Trajan, in that of Madrid, is considered his chef d'œuvre. He died June 29, 1779.

MENIN. [FLANDERS, WEST.]

MENISCUS. [LENS.]

MENISPERMA'CEÆ are an important and extensive natural order of Exogenous plants, considered by some to be polypetalous, and referred to De Candolle's *Thalamifloral* subclass; by others placed among the *Monochlamydeæ* of that author. The wood of the stem is arranged essentially upon the exogenous plan, but has some striking peculiarities. According to M. Decaisne, it has no annual concentric layers. The woody plates are always simple, and do not divide longitudinally, as in other Dicotyledons, but increase each year by the formation of a new woody layer outside the former and inside the liber. The latter ceases to grow after the first year.

Menispermacæ are usually bitter and tonic plants. The species of *Cocculus* called *Bakis*, *Fibraurea*, *cinerascens*, and others, are used in their native countries as a remedy for intermittent fevers. *Cocculus palmatus* furnishes the Calumba Root of the shops, a valuable bitter.

MENISPERMUM, a genus of the natural family of *Menispermaceæ*, which formerly contained numerous species, many of them valuable for their medicinal and other qualities, such as the Calumba Root, and the berries called *Cocculus Indicus*, which are now referred to the genus *COCCULUS*.

MENORCA, or, MINORCA. [BALEARIC ISLANDS; SPAIN.]

MENSURATION is the name given to a branch of the application of arithmetic to geometry, which shows how to find any dimension of a figure, or its area, or surface, or solidity, &c., by means of the most simple measurements which the case will admit of. We need hardly say that a complete treatise on this science would involve every branch of mathematical science.

MENTHA PIPERITA (Peppermint), a plant common in many parts of Britain, but cultivated for medical purposes. The dried plant, which is more powerful than the fresh, is of a lively green, with a peculiar aromatic odour, and a pleasant camphor-like taste, at first burning, but at last causing an enduring sensation of cold in the mouth. The dried herb is used for the preparation of a distilled water and of a volatile oil, from which oil spirits, or essence, of peppermint is prepared. Of the oil three varieties occur in commerce, the German, English, and American.

MENTHA PULEGIUM (Pennyroyal), an indigenous species of mint, smaller than most of the others, and of which the entire herb, except the root, is officinal. The odour is strong and peculiarly aromatic; the taste herbaceous and bitter. It has a stimulant and antispasmodic property, similar to most mints. A distilled water, a spirit, and volatile oil are prepared from it, as from the preceding species.

MENTHA VIRIDIS (Spear-mint), a plant of Britain very much resembling *M. piperita*; the colour, however, is of a deep green. From it are prepared a distilled water, a spirit, and a volatile oil, which are used as the former.

MENTZ. [MAINZ.]

MENURA. [MANURA.]

MENYANTHES TRIFOLIATA (officinal part, the leaves), a plant common in our bogs, and hence called Bog-bean, as its leaves resemble the common bean. It contains an extractive (Menyanthin), which is a tonic and febrifuge medicine of undoubted efficacy. The chief use said to be made of the large quantity annually collected is to substitute it for hops in brewing.

MENZIKOFF. [PETER I., the Great.]

MEQUINEZ. [MOROCCO.]

MERCANTILE LAW AMENDMENT ACT. A very important Act was passed in the 19 & 20 Vict. c. 97, 1856, called the Mercantile Law Amendment Act, whereby it is provided that no person shall be prejudiced in his title to the goods of a debtor though a writ of execution or attachment have been issued against them, unless they have been actually seized or attached before he acquired such title, or unless at the time of acquiring such title he have notice of such writ or attachment being in the hands of the sheriff. It is also enacted that, upon any verdict for a plaintiff who seeks to recover goods, the court may order the delivery of such goods without giving the option to the defendant of paying damages for the non-delivery thereof, and retaining such goods.

Important changes in the law affecting guarantees were made by this Act—viz., that from the date of the Act, it was not necessary as theretofore to express the consideration on the face of it for such guarantee. That a change in the firm of guarantors or guarantees shall not be binding on the person making the

promise for anything done or omitted after the change, unless by express stipulation. Further, that any surety who discharges the liability shall be entitled to the securities held by the creditor.

By the same Act it is provided that all acceptances to a bill of exchange shall be in writing, and signed by the acceptor, or some person duly authorized by him.

Some alterations in the limitation of actions are made. [STATUTES OF LIMITATION.]

The Mercantile Law Amendment (Scotland) Act, 19 & 20 Vict. c. 60, 1856, assimilated the mercantile law of Scotland to that of England in many important particulars.

Upon the law of sale, the principal alterations which it made were:—

By s. 1, that goods sold, but not yet delivered to the purchaser, should not be attachable by creditors of the seller after the date of sale; but that the right of the purchaser to demand delivery of such goods might be attached or transferred to his creditors. By s. 2, that when a purchaser of goods, who had not obtained delivery of them, sold them, the second purchaser might demand delivery of them from the original seller; and that the original seller should not be entitled to retain such goods after receiving intimation of this subsequent sale, except for payment of the original purchase price, or for the performance of obligations or conditions forming part of the original contract of sale. But by s. 3, any seller of goods might attach the same by arrestment or pawning, while they still remained in his hands or possession, at any time prior to the date of intimation of their sale to a subsequent purchaser. By s. 5, if a seller, at the date of sale, was without knowledge that the goods sold by him were defective or of bad quality, he was not to be held to have warranted their quality or sufficiency, unless an express warranty to that effect had been given by him, or unless the goods had been sold for some specified purpose.

With regard to the law of guarantee and cautionary obligations, it was enacted by s. 6, that all such securities should henceforward be in writing. By s. 7, that no guarantee granted to or for a firm should be binding upon the granter after any change of the firm, unless the intention of parties that it should continue to be binding, notwithstanding the change, appeared either by express stipulation or by necessary implication. By s. 8, cautioners were no longer, except upon express stipulation, to be entitled to the benefit of discussion, but creditors might proceed at once against either the principal debtor, or the cautioner, or both. By s. 9, when two or more parties became bound as cautioners, the discharge of the one should operate a discharge of the others.

The principal provisions of the Act, as to bills of exchange and promissory notes, were by s. 10, that their date might be proved by parole evidence; by s. 11, that acceptances should henceforward be in writing; by s. 12, that bills drawn in any part of Great Britain or Ireland, or of the islands of Man, Guernsey, Jersey, Alderney, and Sark, upon any person residing within the above-named limits, should be deemed inland bills; by s. 13, that notarial protest should not be necessary except for the purpose of summary diligence; by s. 15, that where a bill had been lost,

stolen, or fraudulently obtained, the holder would be obliged to prove value given for it: and by s. 16, that where a bill had been endorsed to any person after the date of its payment, the endorsee should be liable to all objections or exceptions to which it was subject in the hands of the endorser.

The Act further provided by s. 17, that carriers for hire should be liable for losses by accidental fire occurring to goods while in their possession.

MERCAPTAN, a compound of hydrogen, carbon, and sulphur, discovered by Zeise, and so called from its energetic action on binocide of mercury (*corpus mercurium captans*). It is a colourless liquid, has a penetrating alliaceous smell, and a peculiar sweetish taste; its specific gravity is 0.842, it boils at 144°, and remains fluid at 8°. Water dissolves it sparingly, but ether and alcohol unite with it in all proportions. According to Zeise it consists of H⁶ C⁴ S².

MERCATOR, GERARD (whose real name was Kauffman, of which *Mercator* is the Latin equivalent), was born at Rüpeldam in East Flanders, in the year 1512. He applied himself with great industry to the sciences of geography and mathematics, was patronized by the Emperor Charles V., and appointed, in 1559, cosmographer to the duke of Juliers. He gave his name to the method of geographical projection now usually employed in the construction of nautical maps, in consequence of his having first represented the meridians by equidistant parallel lines, and the parallels of latitude by straight lines at right angles to the meridian, but he did not know the distance which ought to separate these parallels. [MAP.] Nicholas Mercator is said to have discovered the law which regulates these distances; but the English mathematicians having refused to pay for the promulgation of his discovery by accepting a pecuniary challenge which he is said to have proposed to them, he died without communicating it even to his friends. The credit of first investigating the principles of that projection, and applying them to the purposes of navigation, appears to be due to Edward Wright, who explained them in a treatise published in 1599. Gerard Mercator died at Doesburg, December 2, 1594.

MERCHANDISE MARKS ACT, 1862, defines the word 'mark' to be any name, signature, word, letter, device, emblem, figure, sign, seal, stamp, diagram, label, ticket, or other mark of any other description; and the expression, 'trade mark,' to include every such name, signature, word, letter, device, emblem, seal, stamp, diagram, label, ticket, or other mark, lawfully used by any person to denote any chattel, or (in Scotland) any article of trade, manufacture, or merchandise, to be an article or thing of manufacture, workmanship, production, or merchandise of such person, or to be an article, or thing of any peculiar or particular description, made or sold by such person; and also to include any name, signature, word, letter, emblem, figure, mark, or sign which in pursuance of any statute or statutes for the time being in force relating to registered designs, is to be put to, placed upon, or attached to any chattel or article during the existence or continuance of any copyright, or other seal right acquired under provisions of such statutes. By the Act, forging a trade-mark, or falsely placing any trade-mark with

intent to defraud, or forging a trade-mark to any vessel, case, wrapper, &c., in which any article is sold, is made a misdemeanor, and all persons who sell any such articles are liable to a penalty of a sum equal to the value of the articles sold, and a sum not exceeding 5*l.*, or less than 10*s.* Any addition or alteration to trade-marks, made with intent to defraud, are made forgeries, and any person who may have sold an article with a false trade-mark upon it, may be summoned to give information as to where he procured it. The marking of any false indication of quantity upon an article with intent to defraud, subjects the person to a penalty of a sum equal to the value of the articles, and a further sum not exceeding 5*l.*, and not less than 10*s.*; and the selling of such an article, to a penalty of not more than 5*l.*, or less than 5*s.* The finder of an article with a trade-mark is deemed to contract that the mark is genuine. No proceeding can be taken under the Act after the expiration of three years next after the committing of the offence, or one year next after the first discovery thereof by the person proceeding.

MERCIA. [ENGLAND.]

MERCURIALIS, a genus of plants belonging to the natural order *Euphorbiaceae*. *M. perennis*, Perennial Mercury, is a native of woods and thickets in Great Britain. *M. annua*, Annual Mercury, is a common plant in waste uncultivated lands. It once had a place in the British Pharmacopœia on account of its supposed efficacy as an emmenagogue.

MERCURY or QUICKSILVER (symb. Hg., equiv. 100, sp. gr. 13·6), is one of the so-called noble metals, and possesses the remarkable property of being fluid at ordinary temperatures; it boils at 660° Fahr., giving off vapour of sp. gr. 6·976, and may therefore be distilled; it is solid at -40° Fahr., and contracts at the moment of congelation, and becomes malleable. It is of a silvery white colour, with a striking metallic lustre. In consequence of the uniform rate at which it expands when treated, from considerably below 0° to above 300° Fahr., it is employed in the construction of thermometers. Mercury when pure runs in small spherical drops over smooth surfaces; but when not pure the drops become elongated and *tailed* in form, and leave a gray stain on porcelain or glass. It is a good conductor of electricity, and its capacity for heat is extremely small.

The mercury as imported into this country is commonly contained in iron bottles secured by a screw in the opening, and is usually almost chemically pure. If the presence of other metals is suspected it may be pressed through leather to separate mechanical impurities, re-distilled, and then digested for a few days in dilute cold nitric acid, which exerts little action if more oxidizable metals are present. It is then freed from the nitric acid by washing with distilled water, and is finally dried either by heat or by passing through it clean bibulous paper, when it becomes pure chemically and mechanically. The quantity of mercury imported into the United Kingdom in 1864 was 4,763,499 lbs., value 512,349*l.* Nearly the whole came from Spain and Portugal. This quantity was, however, unusually large; and in 1865 it decreased to 1,781,825 lbs., almost precisely the same as in 1863.

The mercury of commerce is entirely obtained from *cinnabar*, its principal ore, which is a bisulphide of mercury, known also as vermillion, of a brownish red colour, massive and sometimes crystalline. The substance of this latter name used as a pigment, is a sulphide of mercury, but is more frequently an artificial product. It is also found, although rarely, as a *chloride* (which is a grayish translucent substance), and as an *iodide* and a *selenide*. Native or virgin quicksilver occurs only in small quantities, and in cavities of the sulphur ores. Native amalgam, or a compound of mercury and silver, is a white opaque substance, generally crystallized in cubes.

The mines occur in comparatively few places; those of Almaden in Spain, and Idria in Carniola, are the most important. The ore is to be found in upper Hungary, Transylvania, and the district of Zweibrücken in Germany, and it is procured also from the Ludwig mine near Wetzlar, and from the Val Sassina in Lucca; the mine del Siele, near Grosseto, in Italy, yields 7000 lbs. in a year. Mercury is now obtained in large quantity from California; in 1862, 158,661 lbs. were imported from thence.

There are two methods of reducing the metal from its ore. The cinnabar may be burned in a furnace, in which case the sulphur is given off as sulphurous acid, and the mercury is collected in a condensing chamber; or the sulphur may be separated by the action of slaked lime or iron filings, which reagents, with the ore, are put into cast or sheet iron, or earthenware retorts; and the metal on being set free and volatilized by the heat, is condensed by cold.

There are two oxides of mercury, the dioxide or sub-oxide (known also as the black oxide and mercurious oxide), Hg₂O, and the peroxide HgO, which is a red body. The former is an unstable compound, which on exposure to heat quickly passes into the red and the free metal (Hg₂O = HgO + Hg). The peroxide also parts with its oxygen readily on exposure to a pretty strong heat, and is frequently employed by the chemist for procuring that gas in small quantity. The salts of this latter oxide are generally obtained either by its direct solution or by digesting excess of mercury with the acids; as, for example, with nitric or sulphuric acid, when in the former case the nitrate (HgO, N O₅ + 8 Aq), and in the latter the sulphate (HgO, S O₃), are formed.

The haloid salts of mercury are very important compounds, the most important of which are the chlorides; these being the sub-chloride of mercury (Hg₂Cl) or calomel, and the chloride (HgCl) or corrosive sublimate. The sub-chloride or calomel when procured by precipitation, is a white pulverulent substance, whereas that obtained by sublimation is crystalline, hard, and dense. Its sp. gr. is 7·175; it is colourless, inodorous, insipid, and sometimes regular crystals are observed; the primary form of which is a square prism. It melts at 509° Fahr., and volatilizes unchanged at 570°. It is quite insoluble in water. The chloride is a white, semi-transparent, crystalline mass; the perfect crystals appear to be a right rhombic prism. This substance has a specific gravity of 5·4, and the density of its vapour is 9·4. It is soluble in sixteen parts of cold, and three parts of boiling water. It is inodorous, and of a nauseous and acrid taste, and it is a violent

poison. The symptoms produced by a poisonous dose of this salt come on immediately; during the act of swallowing an intense feeling of constriction, and a burning heat in the throat are experienced, while a metallic taste is left in the mouth. Violent pain in the stomach and abdomen is felt in a few minutes, and vomiting of mucus and blood, and purging, follow. The pulse becomes small, frequent, and irregular, the tongue white and shrivelled, the skin cold and clammy, the respiration difficult, and death is preceded by fainting or convulsions. Any dose exceeding two grains would probably prove fatal to an adult, unless vomiting were induced, or the whites of eggs administered. Death commonly ensues in from one to five days, but may take place in less than half an hour, or not for three weeks or more.

Sulphur and Mercury unite in two proportions, forming the sulphide and the bisulphide. The sulphide (M S) is a black powder, insoluble in water, and volatilized at a high temperature. The bisulphide (M S²), before alluded to as forming cinnabar or vermilion, may be produced artificially; it is a compact, deep red, crystalline mass, inodorous, insipid, and insoluble. A black mixture of mercury and sulphur forms the *Ethiops Mineral*. *Phosphorus and Mercury* form a brownish insoluble compound. *Selenium and Mercury* unite to form a tri-coloured substance.

With iodine and bromine mercury forms two iodides and bromides corresponding in composition to the chlorides. Both the iodides are used in medicine; the bromides are of no practical importance. *Metals and Mercury*, or the greater number of them, readily combine; other metal compounds are called *alloys*, but those which contain mercury are called *amalgams*. *Ammoniacal amalgam* is one of those. This fugitive combination is produced by first making an amalgam of metallic mercury with sodium, the union of these two bodies takes place with flashes of flame. Into a tall glass cylinder is then poured a warm solution of chloride of ammonium (sal ammoniac), following which the sodium amalgam is poured in, when the whole swells up to many times the original volume of the materials employed, and becomes a butter of mercury and of sal ammoniac, through its entangling the hydrogen liberated by the sodium from the water of the solution of the chloride of ammonium. In a short time the amalgam subsides, and the metallic mercury reappears. Mercury combines with nitrogen, forming a nitride, Hg₃ N (a brown powder which explodes on being struck with a hammer, or when suddenly heated), and three nitrides of the suboxide of the metal.

Mercury combines with many acids to produce salts; among which acids the chief are—*nitric*, as already stated, *muratic*, *sulphuric*, *carbonic*, *phosphoric*, *fulminic*, and *acetic acids*. The best known of these salts is *Turbeth Mineral*, composed of oxide of mercury and sulphuric acid, and *Fulminate of Mercury*, a detonating substance composed of protoxide of mercury and fulminic acid. This remarkable substance (consisting of 2 Hg₂ O Cy₂ O₂) is prepared by dissolving 100 grains of mercury in a measured ounce and a half of nitric acid, aided by heat. This solution is poured, when cool, into two measured ounces of alcohol in a porcelain basin, and gently warmed; it soon effervesces and evolves ethereal vapour. During this action a gray

precipitate falls, which is to be immediately separated by decantation and filtration, and washed with small quantities of distilled water, and carefully dried at not more than 100° Fahr. The substance thus obtained will detonate by friction or percussion, and is in demand for the manufacture of percussion caps. The cyanide of mercury (Hg Cy) may be prepared by dissolving the red oxide in prussic acid, and is the best source from which to procure readily cyanogen for experimental purposes. In respect to the salts of mercury generally, the soluble salts of the protoxide are mostly white, of a metallic taste, and not virulently active as poisons. Some of them, when neutral, are resolved by water into basic and acid salts. The soluble salts of the peroxide or binoxide are mostly white when neutral, yellow when basic; they are poisonous, and nauseously metallic to the taste, and are often resolved by water into acid and basic salts. Mercurial salts are mostly volatilized at a red heat.

The uses of mercury are so numerous that more than a brief reference to a few of them would be superfluous. It is employed extensively in the extraction of gold and silver from their ores by amalgamation. Its amalgams are much used in the processes of silvering and gilding; and some, as those of copper and cadmium, are employed by the dentist for stopping decaying teeth. It is incessantly in use in the laboratory of the chemist, and is indispensable for making many sorts of philosophical instruments. It is the source of several valuable pigments, of which vermilion is the chief, and the antiseptic properties of one of its chlorides has already been adverted to. Liquid mercury is no longer used in medicine, although until lately it was occasionally given with the view of overcoming by its weight obstructions in the intestinal canal. In such case its effects are supposed to be purely mechanical; but it may, when taken into the system, be chemically acted on, and produce violent disorders.

The medicinal uses of mercury are dependent on preparations of the substance, and their degree of action will, of course, be according to the nature and relation of the substance in any case employed, and to the amount and the mode of its administration. The following are the diseases in which mercurial preparations are held by the profession as of most utility:—(1) In *internal congestions*, as of the liver, &c., to increase the secretions, and hence relieve the vessels of the affected organ; (2) In various *acute inflammations*, especially of serous membranes (q. v.), of the structure of the liver and of the lungs, &c.; (3) In numerous forms of *chronic inflammation*; (4) In *dropsies*, dependent upon inflammation of serous membranes or disease of the liver, but not in dropsy from disease of the kidneys, where they are generally injurious; (5) In numerous *chronic affections* in which an alterative action is required; and (6) As a purgative (to be followed by a black draught), when a patient is in the condition popularly known as bilious (in this case, blue pill is usually as efficacious as calomel).

In *Syphilis* preparations of mercury were at one time an effective mode of treatment. It is now generally considered neither prudent nor necessary to resort to medicaments of this kind for the treatment of such maladies.

If calomel, blue pill, or any other mercurial medicine be given in too large doses, or for too long a period, most serious consequences may result—such as very profuse salivation, with swelling of the tongue and gums, and loosening of the teeth; purging; certain skin affections; disease of the periosteum and of the bones; and a low febrile condition, accompanied with great general prostration.

The doses of calomel for an adult vary from three to six grains when taken as a purgative. If the object is to affect the system generally, as in a case of acute inflammation, small doses (half a grain to two grains, combined with a little opium) should be given several times a day; and even still smaller doses should be prescribed. The *Compound Calomel Pill*, popularly known as *Plummer's Pill* (in which the calomel is associated with oxysulphide of antimony and guaiacum) is a most valuable alterative in chronic skin-diseases—a five-grain pill to be taken every night.

Corrosive sublimate, although a very powerful irritant poison, is extremely useful in very small doses as an alterative in many chronic affections of the nervous system, the skin, &c. The dose varies from one-thirtieth to one-eighth of a grain. This medicine should always be given on a full stomach.

Certain external applications require a few remarks. The plasters, ointments, and liniments are absorbed by the skin, and act in the same manner as mercurial preparations taken internally.

White Precipitate Ointment is the universal remedy for the destruction of lice, and is a useful stimulating application in chronic skin-diseases. *Ointment of Nitrate of Mercury*, called also *Citrine*, or *Golden Ointment*, is a most useful stimulating application in inflammation of the eyelids, in indolent ulcers, &c.; and the *Ointment of Nitric Oxide of Mercury* is similar in its action. [LINIMENTS.]

The *toxicological* relations of the mercurial compounds must be briefly glanced at. There are cases on record in which, probably from some peculiarity of constitution, ordinary and even small doses of the milder mercurials have caused death; thus, Christison mentions a case in which two grains of calomel destroyed life by severe salivation and by ulceration of the throat; and similar cases in which small doses of gray powder, blue pill, and calomel have proved fatal, are recorded by Taylor in his 'Medical Jurisprudence.' These testimonies to the very hazardous character of these medicaments, show that they require skilful handling.

MERCURY, the planet nearest to the sun. Its orbit being entirely within that of the earth, it never recedes to the point of the heavens opposite to the sun, but is always found within 29° of the sun, or 36,000,000 miles. Hence it is only visible to the naked eye in the evening when it is to the east of the sun, and near to its greatest distance (or elongation) from the sun, so that the sun can descend sufficiently below the horizon to allow the planet to be seen just before its setting; similarly, it is only visible in the morning (before sunrise) when it is near its greatest elongation westward of the sun. The phases of Mercury are not visible without a telescope. The apparent diameter of Mercury varies from 5 to 12 seconds: the real diameter is $\cdot 398$ of that of the earth, or about 3140 miles. Its bulk is to that of

the earth as 63 to 1000; its mass is reckoned at the two-millionth part of that of the sun. It revolves on its axis in $24^{\text{h}} 5^{\text{m}} 28^{\text{s}} \cdot 3$. Its orbit is inclined to the ecliptic in an angle of $7^{\circ} 0' 9''$. It has seven times the light and heat of the earth; and its mean distance from the sun is $\cdot 3870981$ of that of the earth.

The transits of Mercury, or passages of the planet over the sun's disc, take place when the conjunction (the inferior conjunction, as it is called, Mercury being between the earth and the sun) happens at the time that the planet is near its node. These transits are not so useful in the determination of the sun's parallax or the longitude of the place of observation as those of Venus. The following are, according to Delambre, the times of the transits which will yet take place in the present century (civil time in Paris):—

1868	4 Nov., 7 A.M.	1891	10 May, 3 A.M.
1878	6 May, 7 P.M.	1894	10 Nov., $6\frac{1}{2}$ P.M.
1881	8 Nov., 1 A.M.		

MERCURY, DEPRESSION OF. [DEPRESSION OF MERCURY.]

MERGANINÆ, a sub-family of the *Anatidæ*, including the *Goosanders*, or *Mergansers* (*Les Harles* of the French), and constituting the genus *Mergus* of Linnaeus.

In the genus *Mergus* the beak is more slender and more cylindrical than in the ducks; each mandible is furnished along its edges with small, pointed, saw-like teeth, directed backwards; the tip of the upper mandible is hooked. In their general aspect and plumage these birds approach the true ducks, but their gizzard is less muscular, and the intestinal canal and its cæcal appendages are shorter.

In the males the lower larynx is dilated into an enormous bulla or drum, partly membranous. Habits, aquatic; food, fishes and their fry. Hind toe lobated.

The members of this genus swim well, but from

Goosander (*Mergus merganser*.)

the weight and flattened form of their bodies appear deeply immersed in the water, the head, neck, and back only being visible. They are also excellent divers, moving, or rather flying, beneath the surface with great rapidity and to a great distance at a time, and by these submarine flights they capture their finny prey. Their flight is strong and swift, and they have great endurance on wing, but from the shortness and backward position of the legs are awkward upon land. They are natives of the colder climates, and

are found during the summer or breeding season in very high latitudes. The males after pairing time are subject to a partial change in the colour of their plumage, similar to that which takes place in many species of the sub-family *Anatina*.—Selby. [DUCKS.] We may enumerate as examples the Goosander (*Mergus merganser*), the Red-breasted Merganser (*M. serrator*), the Hooded Merganser (*M. cucullatus*), and the Smew, or White Nun (*M. albellus*). In a paper on the 'Natural History of Lewis,' laid before the Royal Society of Edinburgh in March, 1866, Dr. Duns stated that the Goosander occasionally breeds in that locality, and that the Red-breasted Merganser is frequently seen there in March and April.

MERGUS. [MERGANINÆ.]

MERIDA. [ESTREMADURA, Spanish.]

MERIDIAN (*meridies*, 'mid-day'). In the heavens the meridian is the circle which passes through the pole and the zenith of the spectator: on the earth it is the circle which passes through the pole and the spectator's position; consequently the terrestrial meridian is the section of the earth made by the plane of the celestial meridian.

The circle derives its name from being that on which the centre of the sun is found at mid-day, or real noon. In the case of a fixed star, the time at which its altitude is greatest is the moment of its coming on the meridian; but in that of the sun or a planet, the orbital motion prevents the moment of its culmination (or coming on the meridian) from being exactly that of its attaining its highest point; though the difference is not worth noting for ordinary purposes.

MERINO, a breed of sheep formerly confined to Spain, but now reared in Saxony, and of late introduced with success into Australia. They are valued for the superior fineness of their wool. The word, which is Spanish, signifies an overseer of pasture lands, and is applied to this breed of sheep because in Spain they are kept in immense flocks under a general overseer, and with right of pasturage all over the kingdom.

MERIONETHSHIRE, a county of North Wales, is bounded N. by Caernarvonshire and Denbighshire, N.E. by Denbighshire, E. and S. by Montgomeryshire, S. by Cardiganshire, and S.W. and W. by Cardigan Bay, an inlet of the Irish Sea. Its greatest length N.E. to S.W. is 45 miles; its greatest breadth N.W. to S.E. is 30 miles. The area is 602 square miles, or 385,291 acres, of which about one-half is common or waste, and about 50,000 acres arable. In 1861 the population comprised 19,145 males and 19,818 females—total, 38,963; being an increase of 120 only, or 0.3 per cent. since 1851. At the last census there were 8499 inhabited houses in the county, 352 uninhabited, and 39 building.

Coast Line and Surface.—The northern part of the coast is formed by the estuary of which the Traeth Mawr and the Traeth Bach are portions. From the Traeth Bach the coast runs south about six miles past Harlech to the little headland on which stands the village of Mochraes or Mochras. The coast is skirted by sands dry at low water, and at some distance out to sea are three sand-banks, the 'Dutch Bank,' the 'Pontigal Bank,' and the 'Sarn Badrig.' This remarkable shoal runs from the immediate neighbourhood of the coast 22 miles out to

sea in a south-west direction; it is composed of sand and gravel. It is dry at the ebb in spring tides, and in storms is marked by fearful breakers. From Mochraes the coast runs S.E. to Barmouth, and thence S. to the Dovey and the Towy. There are few cliffs along the coast. Merionethshire is the most mountainous of all the Welsh counties, and contains some of the loftiest peaks in North Wales. The Berwyn mountains traverse the county from north-east to south-west, skirting the valleys of the Dee, the Wnion, and the Maw. Many of their summits are from 2000 to 3000 feet high. *Cader Idris*, though not the highest, is the most remarkable; its summit consisting of huge columns of crystalline greenstone, like the basaltic columns of the Giant's Causeway. There are other mountain groups and offsets.

The county is almost entirely occupied with the slate rocks which predominate in North Wales. Along the valley of the Dee, as far up as Bala and the valley of the Elwen, a bluish-gray limestone is found, which is quarried for lime, the principal manure employed in the county. Great quantities of white limestone are quarried and burnt for lime near Corwen. Westward of the limestone the rocks are chiefly slaty, forming abrupt and rugged mountains of desolate appearance. Lead and copper mines are worked near Towyn at the mouth of the Disynwy, and copper mines near Barmouth. There are slight indications of volcanic agency among the mountains.

The principal rivers belonging to the county are the Dee, the Maw, and the Dovey, with their respective affluents. The Dee rises near the Berwyn mountains, and flows through Lake Bala into Denbighshire; it receives the Lew, Twrch, Glettwr, Alwen, and other small streams. The Maw, the Dovey, and the Disynwy all rise within the county, and, after receiving many small streams, fall into the Irish Sea.

There are many lakes, most of them small. The largest are Llyn-Tegid, or Bala Lake, 12 miles in circumference, and abounding with trout, carp, and pike; and Llyn-y-Myngil.

Divisions and Towns.—Merionethshire is divided into six hundreds. It is in the dioceses of St. Asaph and Bangor. It is in the North Wales Circuit, and the assizes are held at Bala in the spring, and at Dolgelly in the summer. The county returns one member to Parliament. In 1865 the number of voters on the register was 1527. There are six polling-places, and Harlech is the place of election.

The only towns which require to be noticed are the following:—

Bala (*Llanycil*), a market town, 18 miles N.E. from Dolgelly, is situated at the northern end of the lake called Bala Pool. The town consists chiefly of one wide street. Flannels, woollen stockings, and gloves are manufactured, and a large trade in butter and cheese is carried on. The population of the town in 1861 was 2383.

Bala Pool is the largest lake in Wales. It is 4 miles long, but less than a mile in width, and has an average depth of 40 feet.

Barmouth (or *Aberynaur* or *Llanaber*), a small market town and seaport, 8 miles W. by S. from Dolgelly, is situated on the north side of the estuary

of the river Maw, or Mawddach, at the foot of a lofty mountain, and the houses rise in a succession of terraces, which communicate by flights of steps. A few sloops belong to the port; and timber, bark, copper, hosiery, and flannels are exported. It is resorted to in summer as a pleasant place for sea-bathing. The population of the town is 1600.

Corwen, a market town, $8\frac{1}{2}$ miles W. of Llangollen, is beautifully situate on the Dee, in a picturesque valley, and at the base of the Berwyn mountains. It consists of one street of plain stone houses, with a church, three chapels, school, reading room, &c. The population, mainly employed in agriculture, amounted in 1861 to 2042.

Dolgelly, or *Dôlgellau*, the chief town of Merionethshire, is situated on the south bank of the river Wnion, about a mile above its junction with the Maw. It is 208 miles from London by the Shrewsbury road. The town stands in a pleasant valley, and consists mostly of narrow streets of small houses. Coarse woollen cloths, called 'webs,' and flannels are manufactured; and there are extensive tanneries, fulling mills, and bleaching grounds in the neighbourhood. The church is a neat structure, and there are some places of worship for dissenters. Population of the town in 1861, 2217; parish, 3457.

Festiniog is a small neat town, in the centre of some very attractive scenery. Population of the parish, which includes an area of 16,456 acres, 4553.

Harlech, 14 miles N.W. from Dolgelly, is seated near the shore of Cardigan Bay. It is little more than a village of small size and insignificant appearance, situated between a wild and desolate mountain country and the sea. The most striking object is the castle, the ruins of which are situated on a lofty rock facing the bay, and rising above an extensive marsh once occupied by the sea. Its walls are tolerably perfect; they form a square of about seventy yards each way, with a round tower at each corner. It is a county polling-place.

Townyn, a market town, of one street of plainly-built houses, had a population in 1861 of 2859.

History and Antiquities.—In the earliest period of the authentic history of the island, Merionethshire was included in the territory of the Ordovices. In the Roman division of the island, it was included in the province of Britannia Secunda. It is said to have been called Mervinia by the Romans.

There are several traces of Roman works in this county. Remains of camps exist near Bala, and in the immediate neighbourhood of that town is Tommeny-Bala, an artificial mound supposed to be of Roman origin.

During the Saxon period and the reigns of the earlier English kings of the Norman dynasty, Merionethshire does not appear to have been the scene of events of historical interest.

In the war of the Roses, Harlech was held for the Lancastrians, but was taken by Sir Richard Herbert. In the civil war of Charles I., Harlech Castle was the object of contention. The repeated captures of this place, and a skirmish near Dolgelly, which had been garrisoned for the Parliament, were the only incidents of the contest which occurred within the county.

The principal remains of the middle ages are Harlech Castle, the ruins of Cymmer Abbey, near Dolgelly, and two or three small castellated buildings.

MERLIN, or more properly, MERDHN. Some of the Welsh antiquaries speak of three Merlins: Merdhn Emrys, or Merlinus Ambrosius; Merdhn Wyllt, or Merlinus Caledonius, or Merlinus Sylvestris; and Merdhn ap Morvryn, otherwise called Merlinus Avolonius (from a poem ascribed to him, entitled 'Avallenau,' or the Orchard), and also known by the Latin names of Melchinus, Melkinus, and Mervynus. (Nicholson's 'Eng. Hist. Library.') It is generally agreed, however, that the second and third are the same person; and it is far from improbable that all the three Merlins are but one individual. Of Merlin Ambrosius the principal account we have is in Geoffrey of Monmouth's 'Historia Britonum,' where he is represented as a great prophet and enchanter, who flourished in the time of King Vortigern, or about the middle of the fifth century. Of the Caledonian Merlin there is a life in Latin hexameters, by Geoffrey of Monmouth, who professes to have compiled it from an Armorican original; it is extant in one of the Cotton MSS. Collections of the Prophecies of Merlin have appeared in French, at Paris, 1498; in English, at London, 1529 and 1533; in Latin, at Venice, 1554; and there are also manuscripts of them, in French and English, in the Cotton and other libraries. The 'Avallenau,' and some other Welsh poems, attributed to Merdhn Wyllt, are published in the 'Welsh Archæology,' 3 vols. 8vo, 1801, &c.

MERLIN, the English name for the *Falco Esalon* of Linnæus; *Faucon de Roche* of the French; *Stein*

Merlin (*Falco Esalon*).

Falke of the Germans; *Smerlio*, *Smeriglio*, and *Falchetto* of the Italians.

This beautiful and daring little Falcon (the smallest of the British Falconidæ) is generally distributed through Europe. According to Dr. Richardson it occurs also in North America (Lakes Huron and Superior), and a closely allied species, if not the same, is found in South Africa. In our island it breeds on the moors of some of our northern counties, and according to Mr. Eyton, on Cader Idris in North Wales. [FALCONIDÆ.]

MERLU'CIUS, a genus of fishes, belonging to the *Gadidæ*, or family of Cod-fishes, distinguished by the possession of only two dorsal fins and one anal fin, and the absence of barbule on the chin. This latter character distinguishes the species of the genus *Merlucius* from the Burbot (*Lota*) and Rocklings (*Motella*), and there being only two dorsal fins removes

the present genus from the more typical Cod-fishes, where there are three dorsal fins. As a British example we may mention the Hake (*M. vulgaris*), found on the western and southern coasts.

MERMAID (Ger. *meer*, 'sea,' and *magd*, 'maid'), a mythic creature, supposed to be half woman and half fish, which probably originated in the cetaceous *dugong* and *manatee* (or sea-cow), which suckle their young at the breast. Their fore-fins somewhat resemble arms and hands, and their hinder part terminates in a fish-like tail.

MERO'PIDÆ, a family of Fissirostral birds, of which the Bee-eater (*Merops apiaster*) may be regarded as the type. [BEE-EATER.]

MEROVINGIANS. [FRANCE.]

MERRIMAC, River. [MASSACHUSETTS.]

MERSEBURG is the most eastern of the three governments into which the Prussian province of Saxony is divided, and has an area of 3994 square miles, with a population in 1862 of 831,555. The eastern and larger part of the government has in general a level surface, with gentle eminences, but no mountains; the western portion is more mountainous, being partly occupied by branches of the Harz mountains and the Thüringerwald; this portion, however, contains extensive and fertile levels, and the whole of the government, though the soil is unequal, may be called fertile. The principal rivers are the ELBE and its tributaries, the Schwarze Elster, on the right bank, the Mulde and the Saale on the left; the Saale receives the Elster and the Unstrutt. The government is traversed by the Magdeburg-Leipzig railway, which is joined at Halle by the Weimar-Halle line.

Merseburg, the chief town of the government, is situated on the Saale, 10 miles by railway S. by W. from Halle, and had at the last census, 11,837 inhabitants. The most remarkable buildings are—a fine palace, now used for the government offices; the cathedral, which has one of the largest organs in Germany; the cathedral school; the monastery of St. Peter, in the suburb of Altenburg; the palace of Count Zechi; episcopal palace; school of surgery; the military hospital; and the new town-hall. There are manufactories of various kinds, and extensive breweries and distilleries. The trade of Merseburg is considerable.

Dürrenberg, a small village between Merseburg and Lützen, has important salt-works, which produce about 12,000 tons of salt yearly.

Eilenburg, a town of 9800 inhabitants, stands N.E. of Merseburg, on an island in the Mulde, which is reached by two bridges. The town, which is surrounded by walls and ditches, has manufactories of printed cotton, vinegar, starch, brandy, woollen yarn, &c. Luther preached here at the commencement of the Reformation in 1522.

Eisleben, the birth-place of Luther, is situated 16 miles N.W. from Halle, on a hill above the Buse, and contains several churches, a gymnasium, schools, hospitals, and 9800 inhabitants, who are engaged in a brisk inland trade, in the manufacture of potashes and tobacco, and in linen weaving, and the silver and copper mines and smelting works of the neighbourhood.

Halle. [HALLE.]

Naumburg, a station on the Thuringian Railway,

standing near the right bank of the Saale, is a well-built town, surrounded by walls which separate it from several suburbs. The chief buildings are a fine Gothic cathedral, a hospital, the court-house, the town-hall, and the gymnasium. This town is the seat of the court of appeal for the governments of Merseburg and Erfurt. It has 14,500 inhabitants, who manufacture broad-cloth, cotton, linen, stockings, gloves, leather, starch, soap, vinegar, beer, brandy, and chemical products. Two great annual fairs are held here, one in June, the other in December, for the sale of all kinds of industrial produce; besides these, three other annual fairs are held for the sale of horses and cattle.

Sangerhausen, a well-built walled town, situated at the foot of the Harz mountains, 31 miles N.W. from Merseburg, has 6386 inhabitants, many of whom are engaged in the copper mines and works near the town. Some manufactures of linens and woollens are also carried on. In the place are two castles.

Torgau is a strongly fortified town, 70 miles S.S.W. from Berlin, situated in a low marshy country on the left bank of the Elbe, which is here spanned by a bridge partly of wood and partly of stone. The population is 8961; they manufacture woollen cloth, linen, hosiery, leather, and soap, and trade in corn, timber, and lime.

Weissenfels, a town of 8000 inhabitants, 11 miles by railway N.E. from Naumburg, stands on the right bank of the Saale, which here becomes navigable, and is crossed by a bridge. It is a walled town, entered by four gates, which lead to as many suburbs. On a rock outside the town stands an old castle, now used as barracks. A training house for schoolmasters, a gymnasium, an asylum for deaf mutes, two hospitals, and an almshouse, are the principal institutions of the town. Jewellery, porcelain, leather, and merino, are the chief manufactures. The remains of Gustavus Adolphus, king of Sweden, who fell at the battle of Lützen, are buried in the convent church, now no longer used.

Wittenberg, a fortified town N.N.W. of Torgau, situated on the Elbe, which is here crossed by a wooden bridge 1000 feet long, was celebrated for its university, which was united to that of Halle in 1817, and in which Luther was a professor in 1508. A colossal statue of Luther was erected in the marketplace in 1817, and the university church contains the tombs of him and Melancthon. Luther's cell in the Augustine convent, and Melancthon's house, are still preserved. The town has a theological seminary, a lyceum, gymnasium, several woollen and linen factories, breweries, distilleries, dye-houses, and 11,072 inhabitants, who are also engaged in gardening and in the Elbe fisheries. Wittenberg is on the railway from Berlin to Leipzig. It was taken by assault by the Prussians in 1814. The Reformation began here in 1517.

Zeitz, a walled town entered by six gates, built on the slope of a steep hill, on the right bank of the Elster, 18 miles S.E. from Naumburg, contains a fine old castle, called Moritzburg, a cathedral, a Protestant gymnasium, several churches, a lyceum, a library of 12,000 volumes, and 11,100 inhabitants, who manufacture calico, broad cloth, leather, starch, beer, spirits, pottery, gloves, ribands, &c.

MERSEY. [CHESHIRE; LANCASHIRE.]

MERTHYR TYDVIL. [GLAMORGANSHIRE.]

MERTON COLLEGE, OXFORD. This college was first founded at Malden in Surrey, in 1264, by Walter de Merton, bishop of Rochester and chancellor of England, who in 1274 removed it to Oxford.

The foundation formerly consisted of a warden, twenty-four fellows, fourteen post-masters, four scholars, two chaplains, and two clerks. Under the ordinance framed by the commissioners appointed for the purposes of the statute 17 and 18 Vict. c. 81, the following changes were made:—The fellowships are reduced from twenty-four to eighteen, and are now all open, without any preference in respect of place of birth. The other offices are also thrown open, but their number remains unaltered. The buildings of this college consist of three courts; the outer one, toward the street, was rebuilt in 1589, except the tower and gate, which are of the fifteenth century. The chapel, at the west end of the outer court, is also a parish church, dedicated to St. John the Baptist. It contains, among other monuments, that of Sir Thomas Bodley. (*Oxford University Calendar*, 1866.)

MERULIDÆ, a family of birds embracing the Blackbirds, Thrushes, Dippers (*Cinclus*), Orioles (*Oriolus*), Pittas (*Pitta*), Rock-thrushes (*Petrocincla*), and other denti-rostral genera. Mr. Vigors places this family between the *Laniadæ* or *Shrikes*, and the *Sylviadæ* or *Warblers*.

MERULIUS, a genus of Fungi, deriving its name from *Merula*, 'a blackbird,' some of the species being black. The only known means of preventing the attacks of this and other fungi upon timber is a free circulation of dry air, or the impregnation of the wood with corrosive sublimate.

MERVILLE. [NORD.]

MESEMBRYACEÆ, a natural order of polypetalous Exogens, consisting of plants inhabiting various parts of the world, in very dry temperate climates, but especially the Cape of Good Hope, where the species are extremely numerous. The common Ice-plant of the gardens, *Mesembryanthemum crystallinum*, so called because its cuticle is elevated in the form of multitudes of crystalline points, is burnt in the Canaries for the sake of its ashes, from which barilla is made.

MESENTERY, a term in Anatomy, applied to several duplicatures of the peritoneum, which maintain the different portions of the intestinal canal in their respective situations; allowing, however, more or less motion. They are formed of two laminae, between which are contained the corresponding portion of intestine and the vessels that pass to it. One only of these duplicatures has received the name of *Mesentery*, properly so called. This belongs to the small intestine which it suspends and retains *in situ*. Its posterior margin, which is the smallest, is straight, and descends obliquely from the left side of the body of the second lumbar vertebra to the iliac fossa. Its anterior margin is curved, and corresponds to the whole length of the small intestine.

MESHED, or MUSHED, a fortified city of Persia, the capital of Khorassan, in lat. 36° 17' N., long. 59° 25' E. Population, 100,000. It has manufactures of velvets, jewellery, sword-blades, &c., and gunpowder, and an active trade with Bokhara, Candahar, Herat, and Yzed. The town stands in the midst of

a fertile plain, is inclosed by strong walls about 7 miles in circuit, and contains the magnificent mausoleum of the Imam Riza and the Caliph Haroun-al-Raschid; but its private buildings are mostly of sun-dried brick, and its colleges are in ruins. The mosque is the richest in the world, having an annual revenue of 50,000*l.*, and has two minarets; the doors are studded with rubies, and covered with gold. The shrine is visited by about 30,000 pilgrims every year. The town is by far the most important in north-east Persia, being the centre of numerous converging routes. It is the chief city of the great sect of Shiites, and is thus of nearly equal importance with Mecca, the sacred city of orthodox Mohammedans.

MESMERISM. [ANIMAL MAGNETISM.]

MESNE, in law, a term denoting *intermediate*, or *intervening*. Thus *Mesne process* is generally used in contradistinction to *final process*, and signifies a writ or process issued between the commencement of an action, and the suing out of final process, or execution. By a recent statute the power of personal arrest on mesne process is abolished; and a capture cannot take place until final judgment has been given.

MESOLE, a mineral of a yellow or grayish-white colour, and pearly lustre. It is a fibelliform spar, and occurs in globules of a flat or lamellar structure, radiating from a centre. Its constituents are silica, alumina, lime, soda, and water.

MESOLITE (Gr. *μεσος*, 'middle,' and *λίθος*, 'a stone'), a mineral which occurs in long slender prisms, terminated by translucent quadrilateral pyramids, of a grayish colour, and sometimes colourless; specific gravity, 2.26.

MESOLONGHI, or MISSOLONGHI, perhaps the ancient *Olenus*, in Livadia, a small town in Greece, lies on the northern side of the Gulf of Patras, near its entrance, and right opposite Cape Kologria, or Papas, in the Morea, 22 miles west of Lepanto. It became remarkable during the last Greek insurrection against the Turks, through its siege and capture by Ibrahim Pasha, the commander-in-chief of the besiegers. The heroic resistance of the Greek garrison, and their ultimate fate, made the name of Missolonghi popular over all Europe. Lord Byron died here in 1824.

MESOPOTAMIA is a Greek word which means 'a tract between rivers.' Mesopotamia is called in the Old Testament *Aram-naharaim*, that is 'Aram,' or 'Syria between the two rivers,' and is the ancient name of the country lying between the Tigris and Euphrates. It was bounded on the N. by Mount Masius (*Karajeh Daghi*), a branch of Mount Taurus, and on the S. by the Median wall and the canals which connected the Tigris and Euphrates, by which it was separated from Babylonia. The name of Mesopotamia, which was never employed to designate any political division, did not come into use till after the time of the Macedonian conquest of Asia. It is called by the Arabs in the present day *Al Jezireh*, 'the island.'

Mesopotamia may be divided into two parts. The northern part, from Mount Masius to about 35½° N. lat., is a fertile country watered by the Chaboras and the Mygdonius; the southern part, from the neighbourhood of Circesium to the Median wall, is a flat

and deserted country, which Xenophon has described in the 'Anabasis' (i. 5). The northern part of Mesopotamia was divided into two parts by the river Aborras or Chaboras (*Khabour*), called Araxes by Xenophon, which rises in Mount Masius, and receiving the Mygdonius (*al Hualî*) on the E., flows into the Euphrates at Circesium. Of these divisions the western was called Osroene, and the eastern Mygdonia. The entire region is now comprehended in the pashalics of Diarbekr and Bagdad.

The chief town of Mygdonia was Nisibis, also called Antiochia Mygdonica (*Nisibin*), situated on the river Mygdonius, in a fertile plain at the foot of Mount Nisus.

The chief town of Osroene was Edessa (*Orfa*), in the north-west of the province, 9 geographical miles from the Euphrates. Two days' journey, according to Niebuhr, south-east of Orfa, was the ancient town of Charrae (*Harran*), the Haran of the Scriptures, where Abraham's family dwelt after they had left Ur of the Chaldees. Charrae is memorable in Roman history for the defeat of Crassus.

Circesium (*Kerkesia*), at the union of the Euphrates and Aborras, was a very ancient town: it is called Carchemish in the Old Testament. A little to the north of Circesium, near Thapsacus, was an ancient ford across the Euphrates.

MESOTYPE (Gr. *μεσος*, 'middle, and *τύπος*, 'form'), a mineral occurring in trap rocks (the prismatic zoelite), of a yellowish-brown, red, or white colour. Its specific gravity is 3.2; and its constituents silica, alumina, soda, lime, and water.

MESOZOIC (Gr. *μεσος*, 'life'), the name now given to the middle, or as it was formerly denominated, the secondary of the three great geological periods. It includes the New Red Sandstone, or Triassic, the Lias, the Oolite, the Wealden, and the Cretaceous series, and in England is peculiarly important on account of its wealth in fossil remains.

MESPIIUS, a genus of plants belonging to the natural order *Rosaceae*, and to the sub-order *Pomeae*. The species are trees, natives of Europe, and in a wild state are furnished with spines, which all disappear on cultivation. *M. Germanica*, the common Medlar, is a native of Europe and Siberia. It is found in Great Britain in hedges and thickets, in Surrey, Sussex, and Cheshire. It is cultivated on account of its fruit, which is eaten in a state of decay. Its taste and flavour are peculiar, and greatly esteemed by some persons. [FRUIT.]

MESSAGE, PARLIAMENTARY. An official communication, written or verbal, sent by the sovereign to either House of Parliament. Messages to the Commons to desire any proceedings on their part, are usually written in the sovereign's own hand; those sent when a member of the house is put under arrest on account of the public service are verbal, and delivered by a minister of the department of service concerned. Messages from the Commons to the Lords are sent by one member, but will not be received unless eight at least attend in all. Messages from Lords to Commons are sent by two masters in chancery, or on special occasions by two judges.

MESSE DI CAPELLA, in Music, a term used by the Italians as applicable to masses sung by the grand chorus; in which compositions there are various fugues, double counter-points, and other elaborate

constructions. *Messe Concertati* are masses in which the recitation is intermixed with choruses. (Busby.)

MESSENGERS-AT-ARMS are the officers who execute the writs issuing from the supreme courts in Scotland.

MESSENGERS, KING'S or QUEEN'S. Certain officers employed under the secretaries of state, who carry despatches both at home and abroad. They were formerly employed to serve the secretaries' warrants for the apprehension of persons suspected of high treason, or other grave offences against the state; and it was not unusual for them to keep the prisoners they apprehended in their own houses.

MESSE'NIA, a country of ancient Greece, was bounded on the E. by Laconica, on the N. by Elis and Arcadia, and was surrounded by the sea on the western and southern sides. It was separated from Laconica by the mountain chain of Taygetus; and from Elis and Arcadia by the river Neda and the high land which runs between the bed of the Neda and the sources of the Pamisus. Its area has been calculated by Clinton at 1162 square miles, which is about the area of Staffordshire.

Messenia is described by Pausanias as the most fertile province in the Peloponnesus. The western part of Messenia is drained by the river Pamisus, which rises in the mountains between Arcadia and Messenia, and flows southward into the Messenian bay (Gulf of Koroni). The basin of the Pamisus is divided into two distinct parts. The upper part, usually called the plain of Stenyclerus, is of small extent and moderate fertility; but the lower part south of Ithome is an extensive plain, celebrated in ancient times for its great fertility, whence it was frequently called *Macaria*, or the 'Blessed.' Leake describes it as covered with plantations of the vine, the fig, and the mulberry, and 'as rich in cultivation as can well be imagined.' The western part of Messenia is diversified by hills and valleys, but contains no high mountains.

On the division of the Peloponnesus, after the Dorian conquest under the Heraclidae, Messenia fell to the share of Cresphontes, who fixed his capital in Stenyclerus, and divided the country into five districts. Pylus, however, appears to have retained its independence till a much later time. The history of Messenia belongs to the general history of Greece, and is particularly connected with that of Sparta.

The chief towns on the western coast were Pylus and Mothone, or Methone (*Modon*). The bay of Pylus (*Navarino*), which is protected from the swell of the sea by the island of Sphacteria (*Sphagia*), is the best harbour in the Peloponnesus.

The only town inland of any importance was Messene, at the foot of Mount Ithome, on the summit of which was the citadel. Strabo speaks of this citadel and of Acrocorinthus as the two strongest places in Peloponnesus; and the account of Pausanias, who praises the strong fortifications of the town, is confirmed by the solid and beautiful masonry which remains to the present day. The area of the present government of Messenia is 1329 square miles, and the population in 1861 was 117,181. The capital is Calamoe.

MESSIAH is a Hebrew word, of the same signification as the Greek *Χριστός* (Christ) 'anointed.' In the Old Testament the word is repeatedly applied

to persons who were consecrated to the service of God in some sacred office. Thus the Jewish priests, prophets, and kings are called *anointed* (Messiah), or *the anointed of God*. From this general meaning the word has passed into a particular use, referring to the illustrious personage whom the Jews expected, and whom their descendants still expect, to confer some signal blessings on their nation and the world. The word is found in this sense twice in the Old Testament. (Psalm ii. 2, and in Daniel ix. 25, 26.)

The belief of the ancient Jews respecting the person and office of the Messiah is derived from the passages of the Old Testament which are understood as predictions concerning him. An elaborate examination of all such passages occupies the 4th chapter of the 2nd book of Dr. Smith's 'Scripture Testimony to the Messiah.'

At the time of Christ's advent various expectations respecting the Messiah prevailed among the Jews. It is sufficiently evident from the New Testament, that while some looked for a human prince who was to deliver them from the Roman yoke and exalt them to national supremacy, others expected a divine teacher, who was to confer spiritual blessings not only upon them but also on the Gentiles. The opinion of the Samaritans recorded in John iv. 42, that the Messiah would be a religious teacher and 'the Saviour of the world,' is worthy of special attention, because the Samaritans received no part of the Scriptures but the Pentateuch, and were cut off from all intercourse with the Jews by national hatred.

It is the belief of all Christians that Jesus Christ is the Messiah predicted in the Old Testament. The evidence of this fact is contained in the four gospels, from which it appears that his lineal descent, the place, time, and other circumstances of his birth, life, and death, the miracles he performed, and the doctrines he taught, all agree to the minutest particular with the prophecies respecting the Messiah. For a new view of his life, see the work entitled 'Ecce Homo.' [JESUS.]

MESSINA, a province of the Kingdom of Italy, is bounded W. by the province of Palermo, S. by that of Catania, N. by the Mediterranean, and E. by the Faro or Strait of Messina. The area of the province is 1699 square miles, and the population in 1862 was 394,761. A continuation of the mountainous ridge that crosses Sicily from W. to E. covers the greater part of the surface, and terminates in Cape Pelorus. The streams are numerous, but short: in summer, nearly dry; during the rainy season, torrents. The province contains many beautiful and fertile valleys. Its chief products are silk, hemp, flax, sulphur, wine, oil, and fruit of every sort. The province is divided into four districts, twenty-seven circondarios, and ninety-seven communes. Among the chief towns of the province are those that follow:—MESSINA. *Melazzo*, the ancient *Mylæ*, a seaport town on a promontory of the northern coast facing the Lipari islands, stands 15 miles west of Messina, and has a castle and 10,493 inhabitants, many of whom are employed as sailors and fishermen. *Patti*, on the same coast, 15 miles south-west of Melazzo, has several churches and convents, and 7574 inhabitants. *Taormina*, the ancient *Tauromenium*, on the east coast, an old-looking town

with 2978 inhabitants, is built upon a steep cliff towering above the sea; it has an ancient theatre and other ruins scattered around. *Castro-Reale*, in a valley rich in oil and wine, has 7553 inhabitants. *Mistretta*, in the most western part of the province, has a population of 10,638 (1861).

The islands of Lipari are included in the administrative province of Messina. [LIPARI ISLANDS.]

MESSINA (the ancient *Zancle* and *Messana*), the chief trading town and port of Sicily, lies on the north-east coast of the island. The town is built partly on a declivity, and partly on the sea-shore. The larger part of it rises in the form of a crescent on the west side of the harbour, along which there is a fine quay lined by a handsome row of buildings. The public buildings are—the cathedral, the churches of La Candelara and the Capuchins, which contain some fine pictures; the Greek church of Santa-Maria; the royal palace; the archiepiscopal palace; the arsenal, the loggia, the bank, the convents, the public library, hospitals, theatres, a town hall, exchange, custom-house, lyceum; with a lazaretto on the east side of the harbour. The town has several broad quays, and generally wide streets, paved with lava. The port is defended by a citadel and six forts. Messina gives title to an archbishop; it has a provincial court of appeal, a commercial tribunal, a royal college, and in 1862, 103,324 inhabitants. Some manufactures of damasks and satins are carried on. There are also many tanneries and iron foundries. The port is formed by a strip of sandy beach projecting into the sea south of the town, and sweeping into a semicircle. The harbour, which is about 4 miles in circumference, is one of the best in the Mediterranean. It has deep water throughout, and large vessels can load and unload close to the quays. The chief exports are oranges and lemons, raisins, currants, silk, wine and spirits, olive oil, linseed, salt fish, &c.; the imports consist of colonial produce, cotton and woollen goods, hardware, and other manufactured articles. The total value of all the imports in 1864 was 884,298*l.*; of all the exports, 986,738*l.* The former restrictive quarantine measures having been done away with, and every facility being now afforded to vessels of all nations, foreign shipping at this port has considerably increased during the last five or six years. It has steam communication with Naples, Marseilles, and Malta; and an active tunny and other fisheries. There are three lines of British steamers trading regularly to Messina—viz., fifty arrive and depart every year, with an aggregate tonnage of 20,000 tons, from and to London, touching at several Italian ports; thirty, carrying altogether about 24,000 tons, from Liverpool, for Corfu and Trieste; and thirty more, measuring a total of 10,000 tons, from and to Liverpool and Glasgow, touching at Italian ports. The coasting trade, which was formerly restricted to national vessels, is now open to ships of several nations, but is chiefly carried on by Italian steamers, which touch at several places on the coast of Italy and Sicily. A dry dock, between the Lazaret and Fort St. Salvatore, capable of containing vessels of the largest burthen, has just been completed. Great damage was done to the city in 1848, when it was taken by the Neapolitan troops, after a bombardment of five days, on the 7th of September. Messina surrendered to the Sardinians,

on the 13th March, 1861, and thus became annexed to the new kingdom of Italy.

MESTA, a Spanish word which commonly means a mixture of two or more kinds of corn, but is applied in a particular sense to the union of the sheep of several proprietors in one collective body: of the custom denoted by this particular application of the term, the present article treats. The vast tracts thrown out of cultivation, and left unoccupied after the expulsion of the Moors from Estremadura in the thirteenth century, were soon clothed by nature with rich pasture, which attracted the attention of the upland shepherds of Leon and Castile, who drove their flocks thither to milder winter quarters. The great plague of 1348, which swept away two-thirds of the population of Spain, left many more unclaimed and uninhabited lands in most of the provinces of Spain, and on these also the restless flocks soon encroached. On this custom of migratory pasturage, originating in usurpation, in circumstantial necessity, or in both, the proprietors of the flocks, who have always included the great nobles, conventual and other ecclesiastical corporations, and persons in power, founded a claim, which long possession converted into a prescriptive right, so that the mesta has long been an institution of Spain, regulated by a special code, and guarded by its own judges and courts of law. The number of these migratory sheep at the present time probably exceeds five and a half millions. In the month of April the flocks leave the plains of Andalucia and Estremadura for the cooler pastures of Leon, the two Castiles, and Arragon, whence they begin to return southwards in October. For the lands depastured during the winter months a low price is paid, regulated by usage, and on which no advance is allowed. The sheep are divided into flocks of 10,000, each managed by a conductor, who has under him fifty shepherds and as many dogs. They pass unnoledsted, and feed over the pastures and commons that lie on their road; they are not allowed to traverse cultivated lands, but the proprietors of such lands are obliged to leave a clear space, 85 yards wide on each side of the road, for the passage of the flocks. At night they are penned in with nettings made of the esparto rush. The different routes and the length of each day's journey in these migrations are fixed by immemorial usage. Lambing takes place during the winter sojourn in the south. The sheep-shearing commences in May on the northward journey, and is effected in vast buildings by the road-side, called *Esquileo*, capable of containing 50,000, and some of them 60,000 sheep; the principal of these buildings are in the environs of Segovia.

The Spanish sheep are descended from a cross between the famous Baetican breed and a flock of English sheep sent over with John of Gaunt's daughter, Catherine, on her marriage with the heir of Enrique III., king of Castile. These are said to have been called *marinos* from having come over the sea, and hence by corruption came the name *merinos*. The wool of the sheep belonging to the mesta is celebrated for its fineness, length of fibre, and silky softness; this excellence is said to be owing to the habits of the sheep, whereby they are led to live in almost always the same temperature. The carcass of the mesta sheep is bad; indeed they are prized

only for the fleece; after five years they are useless, having then lost their teeth. The sheep know of themselves when to go northwards, and when to return to the south; and if not led on will set out of their own accord. They are always on the move (except when penned for the night), and from this circumstance they are distinguished from the stationary sheep of Spain by the name of *trashumantes*, or 'wanderers.'

MESTIZO, in Spanish America, the child born of a union between a Spaniard or Creole, and a native Indian.

METAGALLIC ACID is a black, shining, tasteless compound, not dissolved by water, but easily taken up by the alkalies, ammonia, potash, and soda, in solution. It consists of $O^3 H^3 Cl^2$.

METAGENESIS (Gr. *μετά*, 'change,' and *γένεσις*, 'birth'), a term applied to those changes of form which the representative of a species undergoes in passing, by means of successively generated individuals, from the egg to the perfect state: as, the egg of the Medusa develops into a polype, which, assuming a form called Strobila, separates into numerous individual young Medusae. The larval polype produces other similar polypes by gemmation, each of which, after becoming a Strobila, is resolved into numerous Medusae.

METALLURGY is the art of separating metals from their ores. The processes vary for every metal.

METALS. A class of simple or elementary bodies, as distinguished from the non-metallic substances, frequently but improperly called *metalloids*. They are at present supposed to be upwards of fifty in number; namely, aluminium, antimony, arsenic, barium, bismuth, cadmium, caesium, calcium, cerium, chromium, cobalt, copper, didymium, erbium, glucinum, gold, ilmenium, indium, iridium, iron, lanthanum, lead, lithium, magnesium, manganese, mercury, molybdenum, nickel, niobium, norium, osmium, palladium, pelopium, platinum, potassium, rhodium, rubidium, ruthenium, silver, sodium, strontium, tantalum, tellurium, terbium, thorium, tin, titanium, tungsten, uranium, vanadium, yttrium, zinc, and zirconium. This catalogue is constantly liable to be increased by new discoveries, whilst on the other hand, the distinct nature of some of the above may be disproved. The right of certain bodies to be regarded as metals is a matter of grave dispute. Thus arsenic, boron, selenium, silicon, and tellurium are alternately pronounced to be metallic and non-metallic, according to the varying weight assigned to certain analogies. Even hydrogen, a permanent gas and the lightest of all known bodies, has been pronounced a metal, the type of the so-called magnesium group. Hence we see that, like most binary antagonistic classifications, the division of bodies into metallic and non-metallic is of exceedingly little value, and cannot stand a critical examination. With the exception of mercury, which is liquid, the metals are solid at ordinary temperatures, though potassium is soft as wax at the heat of the human hand. All are fusible save arsenic, which when heated passes at once into a state of vapour without liquefaction. Their melting points vary, however, exceedingly. Thus while potassium fuses at 136° Fahr., titanium, platinum, iridium, and tantalum withstand the most intense heat of an ordinary furnace.

Some metals are readily volatilized at moderate temperatures, and may in consequence be distilled. Among these are mercury, potassium, sodium, zinc, cadmium, arsenic, and tellurium, whilst others may be maintained for a long time in a state of fusion without any perceptible loss.

The metals are of all substances the best conductors of heat. If the conducting power of gold be assumed = 1000, that of platinum is 981, of silver 973, of copper 898, iron 374, zinc 363, tin 304, lead 180. Their capacity for heat follows a different series, bismuth and lead ranking first.

The facility with which metals conduct an electric current varies with the temperature. At 32° Fahr. the series is as follows:—Silver, copper, gold, tin, iron, lead, platinum. According to Pouillet each of the following metals is electro-positive towards those which succeed:—Zinc, lead, tin, iron, antimony, bismuth, copper, mercury, silver, gold, tellurium, palladium, platinum. It must, however, be remembered that the relative electric position of a metal is liable to be modified by the nature or even the degree of concentration of the liquid—acid, alkaline, or saline solution—with which it is in contact. The following metals are capable of being rendered *magnetic*, that is, of being attracted by either pole of a magnet, and when suspended between two magnetic poles, of pointing in a straight line between them:—Iron, nickel, cobalt, manganese, chromium, cerium, titanium, palladium, platinum, and osmium. The remaining metals are *diamagnetic*, that is, are repelled by either pole, and if suspended between two magnetic poles, point at right angles to the line of connection.

Copper and titanium are reddish, and gold yellow, but the remaining metals are all of various shades of gray; when in a very fine state of subdivision they appear black.

Their lustre, known as the *metallic* lustre, is peculiar and characteristic. They differ, however, very considerably in the degree in which they possess this attribute, and in many it is only temporarily elicited under the burnishing steel. The metals are generally considered perfectly opaque, even when reduced to thin leaves. Gold leaf, however, which is only 1-200,000th of an inch thick, transmits a portion of greenish light. It is probable, therefore, that the other metals also would be semitransparent could they be rendered sufficiently thin.

A high specific gravity was formerly supposed a characteristic attribute of metals—a notion overturned by the discovery of potassium and sodium, which are so light as to float upon water. Gold and platinum are the heaviest bodies known, the density of the latter being 22½.

Some metals, such as gold, silver, copper, tin, lead, cadmium, zinc, iron, platinum, palladium, potassium, sodium, nickel, and frozen mercury, are malleable, *i.e.*, admit of being hammered out into plates or leaves. The remainder are more or less brittle, and some, such as arsenic, antimony, and bismuth, are readily reduced to powder. Gold is the most malleable. Certain malleable metals are ductile, or capable of being drawn into thin wire. Gold, silver, platinum, iron, and copper are most to be noted in this respect. The ductility and malleability of the same metal are not always in proportion. Iron is

the most tenacious, and titanium the hardest metal. The structure of metals is lamellar, granular, fibrous, or crystalline. Bismuth, tin, and copper readily assume a crystalline form.

In a chemical point of view metals are divided into *light* and *heavy*. The former when united with oxygen yield alkalies and earths, whilst the latter under the same circumstances form what are known as metallic oxides.

All metals may be combined with oxygen. Some take up this element at common temperatures from air or water, whilst others—the so-called *noble* metals—can only be oxidized by the aid of acids, and readily resume the metallic state. Some of the oxygen compounds of metals are acid, others basic, and others again, the suboxides and peroxides, play neither part.

Metals form numerous and important compounds with chlorine, bromine, iodine, fluorine, and sulphur; but their combinations with hydrogen, nitrogen, carbon, and boron are few, and in general of little moment.

Among themselves metals form a class of compounds known as alloys. These are generally harder and more elastic than the metals of which they are composed, and are in consequence, of great utility in the arts and manufactures. Brass, bronze, pewter, white metal, German silver, bell-metal, type-metal, solder, and the compounds of silver and gold used for coinage and jewellery, are the most important.

Most of the metals are readily soluble in acids. Platinum, however, can only be dissolved in hot concentrated nitro-muriatic acid, and upon iridium even this acts but very feebly.

METAMORPHIC ROCKS (Gr. *μετά*, and *μορφή*, 'form'), those rocks or materials of the earth's crust which are not now in the condition in which they were originally accumulated; such as marbles, quartzites, slates, gneiss, micaceous and other schists, sandstones, shell limestones, and the like.

METAMORPHOSIS OF PLANTS. [VEGETABLE MORPHOLOGY.]

METAPHYSICS. Metaphysics is a word which has received definitions various and apparently contradictory, but the most important of which are, nevertheless, ultimately reconcilable. The best conspire in representing it as the science of the primary principles of human knowledge, or which determines the ultimate meaning, foundation, and limits of our beliefs. It is, in short, the science of the sciences—the regulative science of human knowledge and belief. And as the solution of its principal problems implies a systematic study of Mind, it has also been described as the science of the facts—the fundamental facts in the universe—or phenomena of consciousness. As expressive of summary or ultimate science, or at least of the aspiration after it—the aspiration after the purification and perfection of our intellectual life, Metaphysics and Philosophy are used often as synonyms.

The origin of the term Metaphysics is obscure. It was probably first applied to those books of Aristotle which profess to unfold a Science of Being, and which, in the arrangement of his works, followed his Physics. They were accordingly called by his editors 'those after the Physics' (*τὰ μετὰ τὰ φυσικά*); and by the Stagyrite himself, they are referred to under

the names of Theology, First Philosophy, and Wisdom (σοφία). Discussions essentially metaphysical in their character constitute the Dialectic of Plato; which is conversant with a phase of the problems common to it with the Wisdom of Aristotle, and with the metaphysical systems of modern Europe.

Modern is distinguished from ancient Metaphysics by its closer relation to the facts or phenomena of human consciousness. The metaphysical aspiration was originally directed to *being* as distinguished from *phenomenon*; because the former implied the notion of the permanent and necessary, as contrasted with the transitory and contingent, which entered essentially into the ancient conception of a phenomenon. Being or the Real was regarded as necessary and eternal; phenomena or the apparent, as contingent and temporal; and as the ideal of the metaphysician is in the former and not in the latter, Being was regarded as the common object of all high philosophical study. But metaphysicians have sought to contemplate Being or the Real either in abstraction from, or else in and through means of, the successive phenomena of human consciousness. At the former of these two points of view, commencing with abstract axioms about Being as such, they have sought to deduce *à priori* the essential characteristics of its evolutions in time; at the latter of these two points of view, they have sought *à posteriori* to determine the limits of the intellectual power of man, as well as the nature and origin of those conceptions of necessity, permanence, and objective externality, of which we are conscious. The abstract or *à priori* point of view is common to ancient and mediæval with some modern metaphysicians; the analysis of our conscious life, and especially of intelligence, for metaphysical purposes, is more particularly characteristic of the modern mind. In Aristotle, Spinoza, and Hegel, we have specimens of abstract and demonstrative metaphysics; in Locke, Kant, and among the Scotch metaphysicians, we have investigations into the actual possibility of an *à priori* metaphysics which transcends our presentative and representative experience. The *possibility* of a necessary Science of Being as such, is the problem discussed, and resolved in the negative by Locke, Kant, Reid, and Hamilton; while these philosophers have differed among themselves in their manner of describing and analyzing the conscious life by which human science is according to them determined and limited.

The various points of view thus occupied by metaphysicians have suggested a variety of names applicable to portions and phases of the metaphysical province. As the Science of Being *per se*, or in its most abstract character, and aloof from an inductive analysis of our entire conscious experience, it is called Ontology. As the science of Supreme and Absolute Being, or God, it is Theology. As a science purely speculative, and having for its objects supersensual ideas, unattainable by presentative experience, it is Transcendental Philosophy. As an inquiry into the possibility of ontological, theological, and supersensual science, in consistency with the constitution of human nature, it is Intellectual or Rational Psychology. As an induction of the phenomena of an embodied consciousness, in the spirit of merely physical research, it is Empirical or Inductive Psychology.

A course of metaphysics may be introduced by

descriptions of our ideas and conscious life, as intelligent, emotional, and volitional; and inductions of the laws of our conscious states as spontaneously associated. The course or system itself consists properly of two great problems—the problem of finite, conditioned, or relative existence, suggested by the Perception through which we are brought in the senses into relation with an External World; and the problem of Infinite or Unconditioned existence and Absolute Reason or Science, with the mass of speculative thought to which it has given rise, by which the history and character of opinion on all questions has from age to age been more or less determined.

Metaphysics, or the Science of Knowledge and Belief in its *ultimate principles*, is the complement to Logic, or the Science of Knowledge and Belief as *reasoned*. The latter is the introduction to, and the former the consummation of, education in philosophy. [LOGIC, PHILOSOPHY.]

As examples of works expository of modern metaphysics, the reader may be referred to the *Meditations and Principles of Philosophy* of Des Cartes; the *Essay* of Locke; the *Principles of Human Knowledge* of Berkeley; the *Critik of the Pure Reason* of Kant; the *Essays* of Reid, with the *Notes* of Sir W. Hamilton, and his other metaphysical works.

METEMPSYCHO'SIS (μετεμψύχωσις), derived from a Greek word signifying the passage or transmigration of souls, forms a part of the philosophical or religious belief of the Hindus. The migration of souls from one body to another also formed a leading feature of the Pythagorean doctrine, and was a part of the Egyptian religious system.

METEORIC STONES, or *Aérolites*, are bodies which have fallen upon the earth from the atmosphere, and are named from *ἀήρ* (*aēr*), 'atmosphere,' and *λίθος* (*lithos*), 'a stone.' The generic name of *Luminous Meteors* is now, however, more commonly adopted, and includes falling or shooting stars, bolides, and the like. The fall of stones from the atmosphere was known to the Greeks; but the first man of science in modern times who directed attention to the subject of *aérolites* was Chladni, a German philosopher, who, in a tract published at Riga and Leipzig, in 1794, upon the mass of native iron found by Pallas in Siberia, maintained the credibility of the traditions of that and other stony bodies having fallen from the air. From that time greater attention than before was paid to the popular accounts of meteoric stones. In 1796 a stone was exhibited in London, weighing fifty-six pounds, which was said to have fallen in Yorkshire, in December of the preceding year. In the year 1799, Sir Joseph Banks received a circumstantial account, accompanied by specimens, of a fall of stones from the atmosphere, which was said to have taken place near Benares, in the East Indies, in the preceding December; and as these specimens were nearly identical with the Yorkshire stone, incredulity began to give way. It was not, however, until the appearance of a paper by Howard, in the 'Philosophical Transactions' for 1802, giving an account of his analysis of the Benares stone, that men of science declared their belief in the phenomenon.

A detailed description of one very remarkable shower of stones will illustrate the subject generally. On the 26th of April, 1803, at one o'clock in the

afternoon, the sky being clear, with the exception of a few light clouds, a ball of fire was observed in Normandy, in many places far distant from each other—namely, Caen, Falaise, Alençon, Verneuil, and Pont Audemer, which moved rapidly from south-east to north-west; and about the same time, in the district of L'Aigle, loud explosions were heard, which lasted from five to six minutes, resembling the sound of cannon and musketry, and were followed by a long-continued noise, like that of many drums. The meteor from which the noise proceeded appeared not so much like a ball of fire, but rather like a small rectangular cloud, which, during the phenomenon, seemed not to move; but the vapour of which it consisted was sent out, after each explosion, in all directions. It seemed to be about half a league north-west from L'Aigle, and must have been at a very considerable elevation, as it appeared to the inhabitants of two villages, more than a league distant from each other, to be immediately over their heads at the same instant. Throughout the whole district over which the cloud hung, there was heard a hissing noise, like that of a stone from a sling, and a vast number of stones fell to the ground. The space on which they fell formed an ellipse of two leagues and a half long by one broad, the largest diameter being from south-east to north-west, the direction in which the meteor moved: the largest stones were found at the south-east end of the ellipse, and the smallest at the opposite extremity. Above two thousand were collected, and they varied in weight from two drams to seventeen pounds and a half.

Ærolites, when taken up soon after their fall, are extremely hot. They are generally angular, of prismatic and pyramidal forms, the angles being rounded; their broken irregular surface is coated with a fused black crust, like varnish, seldom exceeding 1-50th of an inch, or a quarter of a line, in thickness. When broken, they differ a little in appearance; but they are, for the most part, composed of a collection of small spherical bodies, of a gray colour, imbedded in a gritty substance, and often interspersed with yellow spots. One of the most remarkable circumstances is the great similarity of composition of all the meteoric stones, on whatever part of the earth they have fallen. Iron, nickel, silica, magnesia, and sulphur are the chief ingredients, especially iron; but the earths, alumina and lime, the metals manganese, chrome and cobalt, together with carbon, soda, and water, have also been found in minute and variable quantities. No new substance, nothing with which we were not already acquainted, has ever been discovered in their composition.

Chladni has compiled a very copious catalogue of all recorded instances, from the earliest times: of which twenty-seven are previous to the Christian era; thirty-five from the beginning of the first to the end of the fourteenth century; and eighty-nine from the beginning of the fifteenth to the beginning of the present century. Within the last fifty years a vast number have been recorded; but the actual number must greatly exceed the recorded instances. Livy, Plutarch, and Pliny all speak of meteoric stones which had fallen in ancient times.

Besides ærolites properly so called, masses of malleable iron, often of vast size, have been found

in situations which, together with their composition, leave no doubt as to their being of meteoric origin. An immense mass, seen by Pallas in Siberia, was found quite insulated, at a great elevation, on a mountain of slate near the river Yenesei, removed from everything that could excite suspicion of its being a production of art, and totally different from any ore of iron seen either before or since that time. The mass, which weighed about 1400 lbs., was of an irregular form, not solid, but cellular like a sponge, the cells containing small granular bodies of a glassy nature, afterwards found to be the simple mineral olivine, so common in basalt. Another vast mass of meteoric iron was found in South America in 1778, about 500 miles north-west from Buenos Ayres. It lay in a vast plain of above a hundred leagues in extent, half sunk in the ground, and the size was such as, estimating it by the specific gravity of iron, would give a weight of more than thirteen tons. According to the analysis of Proust and of Howard, it contains 90 per cent. of iron, and 10 of nickel. Another mass was found in Brazil, about 50 leagues from Bahia, the weight of which was estimated at 14,000 lbs. Many other instances of similar masses of iron might be mentioned, which are evidently of meteoric origin; but the only instance on record of iron having been actually seen to fall from the atmosphere, is that which took place at Agram, in Croatia, in 1751. On the 26th of May, about six o'clock in the evening, the sky being quite clear, there was seen a ball of fire, which shot along with a hollow noise from W. to E., and after a loud explosion, accompanied by a great smoke, two masses of iron fell from it, in the form of chains welded together. The average number of meteors which traverse the atmosphere daily has been estimated at 7,500,000. In 1799 and 1833 they were so numerous that 34,000 fell per hour.

Ærolites and meteoric iron are not the only products of meteors which have fallen upon the earth after explosion. Numerous instances are mentioned of black and red dust, which has covered great tracts of land; and of the fall of a soft gelatinous matter of a red colour like coagulated blood, which may have given rise to stories of the sky having rained blood. Such appearances have not unfrequently accompanied the fall of stones.

The origin of this remarkable class of natural phenomena is involved in great obscurity, and many different theories have been proposed to account for them. By some they have been supposed to be bodies ejected from distant volcanoes belonging to our earth. Another hypothesis is, that meteoric bodies are formed in the atmosphere. A third that they are bodies thrown out by the volcanoes which are known to exist in the moon, with such force as to bring them within the sphere of the earth's attraction. But the theory most consistent with all known facts and laws of nature is that proposed by Chladni, viz., that they are bodies moving in space, either accumulations of matter as originally created, or fragments separated from a larger mass of similar nature. Davy remarks, 'The velocity of motion of these bodies must, in all cases, be immensely great, and the heat produced by the compression of the most rarefied air from the velocity of motion must be probably sufficient to ignite the mass; and all the

phenomena may be explained, if *falling stars* be supposed to be small solid bodies moving round the earth in very eccentric orbits, which become ignited only when they pass with immense velocity through the upper region of the atmosphere, and if the *meteoric bodies* which throw down stones with explosions be supposed to be similar bodies which contain either combustible or elastic matter.'

The latest views on this subject regard meteors rather as being planetary than mere satellites of the earth. Humboldt says, in his '*Kosmos*,' 'Shooting stars, fire-balls, and meteoric stones are, with great probability, regarded as small bodies moving with planetary velocity, and revolving in obedience to the laws of general gravity in conic sections round the sun. When these masses meet the earth in their course, and are attracted by it, they enter within the limits of our atmosphere in a luminous condition, and frequently let fall, more or less strongly heated, stony fragments, covered with a shining black crust.' The fire-balls which are occasionally seen to shoot across the sky, have been estimated at from 500 to 2800 feet in diameter; their height, when visible from the earth, at from 16 to 140 miles; and their velocity of motion at from 18 to 36 miles in a second. The regular recurrence of shooting stars, about the middle of the months of August and November of each year, is considered to confirm this astronomical view of the origin of meteorolites; and different days throughout the year have been marked as distinguished by these phenomena, as if there were streams of these small bodies near the earth on those days. Humboldt's final views may be gathered from the following:—'The different meteoric streams, each of which is composed of myriads of small cosmical bodies, probably intersect our earth's orbit in the same manner as Biela's comet. According to this hypothesis, we may represent to ourselves these asteroid-meteors as composing a closed ring or zone, within which they all pursue one common orbit.'

The origin and composition of these remarkable bodies remains, however, a constant subject of scientific speculation. The most recent theory is that propounded by the eminent physicist, Mr. H. C. Sorby. In his paper in the '*Proceedings of the Royal Society*' he says that, in the first place, it is important to remark that the olivine of meteorites contains most excellent 'glass cavities,' similar to those in the olivine of lavas, thus proving that the material was at one time in a state of igneous fusion. The olivine also contains 'gas cavities,' like those so common in volcanic minerals, thus indicating the presence of some gas or vapour. To see these cavities distinctly, a carefully-prepared thin section and a magnifying power of several hundreds are required. The vitreous substance found in the cavities is also to be met with outside and amongst the crystals, in such a manner as to show that it is the uncrystalline residue of the material in which they were formed. It is of a claret or brownish colour, and possesses the characteristic structure and optical properties of artificial glasses. Some isolated portions of meteorites have also a structure very similar to that of stony lavas, where the shape and mutual relations of the crystals to each other proved that they were formed in situ on solidification. A structure is also found so remarkably like that of consolidated volcanic

ashes as to be mistaken for it. It would appear that after the material of the meteorites was melted, a considerable portion was broken up into small fragments, subsequently collected together, and more or less consolidated by mechanical and chemical means, amongst which must be classed a segregation of iron, either in the metallic state or in combination with other substances. 'There are,' says Mr. Sorby, 'certain peculiarities in physical structure which connect meteorites with volcanic rocks, and, at the same time, others in which they differ most characteristically—facts which, I think, must be borne in mind, not only in forming a conclusion as to the origin of meteorites, but also in attempting to explain volcanic action in general.'

On the 25th of August, 1865, some remarkable meteorites fell in the territory of the tribe of Senhadja, Algeria, of which a native Arab gave the following graphic description:—'It was about midday,' he says, 'I was returning from the forest, when all at once I heard a violent report, not unlike that of several pieces of cannon. I was surprised and looked around me. It could not be thunder, for an instant before the sky had been quite clear. Almost at the same instant I heard a rumbling noise in the air. I crouched down, recommending my soul to God, thinking I must be crushed by the object coming from the sky; but at that moment the object fell near me, throwing up a cloud of dust. I ran to it, quite astonished at my not being dead, and found it was a stone. In attempting to get it out of the hole, I was obliged to withdraw my hand immediately, for I felt an excessive heat. I waited some time, and then went to fetch other persons with pickaxes, and in the course of the evening we got out the stone, which had lost nearly all its heat. We broke off some pieces in order to preserve them carefully as amulets against infernal spirits, and then we carried it to the caid.' From subsequent information collected by M. Grenade, a surveyor, it appears that the original shape of the stone was a parallelepipedon with a nearly square base, but with its faces bulging out a little in the middle. It was 35 centimètres long, about 16 feet deep and 22 feet broad; it weighed 25 kilogrammes. The hole it had made in the ground was 50 centimètres deep. The ground, it is true, was soft to the depth of about 20 centimètres, but at that depth was a very hard limestone.

METEOROLOGY, derived from the Greek adjective, *μετεωρος*, signifying 'suspended in the air,' is the science which treats of the atmosphere, and the various causes which affect its condition. The most important of these are temperature and watery vapour, which by their combined effect produce variations in pressure, wind, and rain or other downfall.

For information relative to the chemical constitution and the mass of the atmosphere, we must refer to the article *ATMOSPHERE*.

Temperature.—The temperatures of the atmosphere and of the surface of the earth are dependent on the amount of heat received by radiation from the sun, and also inversely on the amount radiated away into space. It is probable that the atmosphere presents less resistance to the admission of heat from the sun than to its escape, so that the presence of the atmosphere tends on the whole to make the earth warmer. The lower strata of the atmosphere are

warmer than the higher, and have nearly the same mean temperature as the surface of the earth.

In general, the temperature of the surface of the earth and of the lower strata of air is greatest near the equator, and diminishes as we recede from it—a difference which is obviously owing to the greater obliquity of the sun's rays with increasing latitude. But other causes modify this effect, and, in fact, the system of *isothermal lines*, *i.e.*, lines drawn through those places which have the same mean annual temperature, is found to differ very considerably from the parallels of latitude. (See Plate.) The hottest portion of the land is Central Africa, about 10° north of the equator, and the hottest portion of the open sea is in the Pacific, a few degrees south of the equator, the mean temperature of the air in both these regions being about 84°. In like manner the north pole is (probably) not the coldest part of the northern hemisphere. It appears that there are two poles of cold (*i.e.*, centres of greatest cold in the northern hemisphere, both situated between lat. 75° and 80°, one of them to the north of Siberia, in about 120° east long., the other to the north-west of Baffin's Bay, in about 80° west long., their mean temperatures being from 1° to 3°. The mean temperature of the British Isles is much higher than that of most places in the same latitude, being for the centre of Great Britain about 50°, which is the same as that of New York, although the latter place is about 13° further south. The high mean temperature of the British Isles is owing to the prevailing south-west winds, which blow from a warm region of the Atlantic, and arrive at our shores laden with warmth and moisture. These winds in their course pass over the Gulf Stream, which is a current of warm water of great breadth and depth flowing through the ocean. It takes its name from the Gulf of Mexico, from which escaping through the Gulf of Florida, it flows in a N.E. direction as far as about 38° N. lat. It then turns to the eastward and becomes gradually wider and less rapid, until, after passing halfway across the Atlantic, its course can with difficulty be traced. It would appear that one branch of it winds round to the southward and loses itself in that part of the ocean called the Sargasso Sea; while another branch takes a north-easterly course past the coast of Ireland, Scotland, and Norway, contributing materially by its vicinity to the relatively high temperature of these countries.

But the climate of a place, as regards temperature, depends not only on the mean temperature (*i.e.*, the average of all times of the year), but also very much on the *range* of temperature (*i.e.*, the difference between the hottest and coldest times). Small islands in the midst of large oceans have always a very small range of temperature, while the interior of large continents has a very large range. This difference is caused by the different properties of land and water as regards heat. The heating of land by the sun's rays takes place principally at the surface, which is many degrees warmer in summer, and colder in winter, than the soil a few feet deeper—a state of things which never exists in the ocean, where the intermingling of the waters renders any considerable difference of temperature impossible. Another obstacle to variations of temperature at sea is the latent heat of steam—increase

of temperature producing increased evaporation, which is a cooling process; while, on the other hand, when much moisture is present in the air a fall of temperature produces condensation, a warming process. The equable climate of Great Britain, which is warmer in winter and cooler in summer than the continent of Europe, is mainly owing to the amount of moisture present in its atmosphere, or both these peculiarities are owing to the vicinity of the ocean, and to the winds which blow thence.

Moisture is another important element of climate. The amount of water which can be held in the form of vapour within a given space of air, depends chiefly on the temperature; the warmer the air, the greater is the quantity of vapour that it can contain. Vapour is never absent from any portion of the air which we breathe; and, on the other hand, it is very rarely that the full amount of vapour which can be contained is actually present. When this full amount is present, the air is commonly said to be *saturated*; but the phrase is objectionable as regards scientific accuracy, inasmuch as the quantity of vapour which can be contained in a given space at a given temperature is the same, whether the space is empty or full of air; so that if the word saturation is to be applied at all, it should be to the space, not to the air contained in the space.

When the amount of vapour present in the atmosphere is less than usual, we experience a feeling of harshness in the air; on the other hand, an excess of vapour produces a feeling of closeness. In the former case perspiration is rapidly evaporated, and the skin has consequently a tendency to dryness; in the latter case, from slowness of evaporation, perspiration speedily becomes sensible.

Since the amount of vapour necessary for saturation increases with the temperature, it is obvious that by lowering the temperature we produce an approach to saturation. When air (containing vapour) is cooled to such an extent as just to produce saturation, it is said to be cooled down to its *dew-point*. If it is cooled below this point a portion of its vapour will pass from the gaseous to the liquid form, and will be deposited in the form of dew or rain. In nature, dew is produced by the cooling of the ground below the dew-point of the air in contact with it; while rain is produced by the cooling of a mass of air below its dew-point. This latter result may be obtained indirectly by the mixing of two portions of air at different temperatures; for although each portion may be able to hold its own vapour before the mixing takes place, it may easily happen that the mixture will be over-saturated, and must therefore deposit the excess of moisture in the form of rain. The quantity of vapour which air can contain, though it increases with the temperature, does not increase in simple proportion; and the law of increase is such that if two portions of air equally moist and unequally warm are mixed together, the mixture is more moist than either of its components. We use the word *moist* here in the sense of the technical term *humidity*. The *humidity* of a mass of air is the ratio of the vapour actually present in it to the quantity of vapour requisite for saturation. In this sense one portion of air may be more moist than another, and, at the same time, may contain a less weight of vapour per cubic foot.

The *dew point* of air may be directly measured by cooling a polished surface until it is seen to be dimmed by the deposition of dew. This is the principle of the hygrometers of Daniell and Regnault, the dew being in both these instruments deposited on the bulb of a thermometer. *Humidity* is most easily measured by two thermometers, one of the ordinary kind and the other having its bulb covered with muslin moistened with water. The evaporation from the moist bulb produces cooling, and this effect is greatest when the air is driest. Hence the difference of the readings of the two thermometers is a measure of the dryness of the air; and tables have been published showing, for any two readings of the thermometers, what is the dew-point and what the humidity. [HYGROMETER.]

Pressure, tension, or elastic force, is another variable quality of air. To understand the idea conveyed by these names (which are used interchangeably), it must be premised that every gas or mixture of gases has a tendency to expand, and exerts an expansive force equally in all directions, so that if confined in a cubical box with two sides horizontal and the other four vertical, the pressure exerted on all six sides would be the same. This expansive force is usually expressed in terms of the pressure exerted on each square inch of surface in contact with the gas; thus, the mean pressure of air in the latitude of Paris, at the level of the sea, is 14.7304 lbs. per square inch. If there were no movement in the atmosphere, the pressure per square inch at any place on the earth's surface would be equal to the weight of a vertical column of air one inch square, extending through the whole depth of the atmosphere. From this connection between pressure and weight of air, the name 'barometer' (literally, weight-measurer) has been given to the instrument which really indicates, not the weight, but the pressure of the air. [BAROMETER.] From the habitual use of this instrument, in which the pressure of air is balanced by the weight of a column of mercury, it is common to speak of the pressure of the air, or of any constituent of the air, as being so many inches of mercury. The mean pressure at sea level in the latitude of Paris is 29.922 inches, the mercury being at the freezing point of water.

The variations which occur in this element are mainly due to variations in temperature and moisture. Air when warmed expands, and consequently becomes specifically lighter, thus acquiring a double tendency to rise above the surrounding air; and when it has so risen it must, from the tendency of fluids to find their own level, overflow laterally. The addition of moisture affects air in two ways; first, by increasing its mass or total quantity; secondly, by rendering it specifically lighter, in virtue of the fact that steam or vapour of water is lighter than air at the same temperature. When vapour is condensed into rain, and still more when it is frozen into snow or hail, the temperature of the containing air is raised by the latent heat given out by the vapour. These causes concur to produce both vertical and lateral movements of air, and when from these or other causes an excess of air is accumulated over any region of the earth's surface, the increase of pressure thus produced will be indicated by a corresponding rise in the barometer.

If observations of the barometer be taken regularly at stated hours, it will be found that there are indications of a regular *diurnal variation*, the greatest pressures on the average (say) of a month, being at about 10 a.m. and 10 p.m., and the lowest about 4 a.m. and 4 p.m., the times differing, however, somewhat according to the season of the year. This variation is the joint effect of solar heat and evaporation, which, to a certain extent, counteract each other in their effect on the barometer.

The *annual variation* of the barometer also presents the phenomenon of a double maximum and minimum.

Dividing the whole pressure into the two portions due respectively to dry air and vapour (the irrelative proportion being known by observations on the humidity of the air), it is found that the pressure of dry air attains its maximum at midwinter and its minimum at midsummer, while the times for the other portion are just the reverse. It is to this opposite variation of the two elements of pressure that the total effect of a double maximum and minimum is due.

When it is summer in one hemisphere, and consequently winter in the other, the colder hemisphere acts as a condenser for receiving the moisture evaporated in the warmer. The pressure of vapour is greater in the warmer hemisphere, and the pressure of dry air is greater in the colder. Owing to the excess of water in the southern hemisphere, the pressure (or amount) of vapour is greater in that hemisphere on the average of the year, than in the northern, but the pressure of dry air is less; and from the lightness of vapour as compared with dry air, the total pressure is also less.

Wind is, in the first instance, the direct result of difference of pressure. When a body of air is pressed with greater force on one side than on the other, it yields to the greater pressure; hence, as a rule, the wind blows from regions of high to those of low barometer, and whenever the barometer falls unusually low a storm of wind usually follows.

The phenomenon of *land and sea breeze*, so well known in tropical regions bordering on the sea, is produced by the unequal heating of land and sea. During day, the sun's rays render the land very warm, while they have comparatively little effect on the temperature of the surface of the sea. Hence the air over the land becomes warmer and lighter than that over the sea, and when the former ascends in virtue of its lightness, the latter rushes in to supply its place; thus producing the agreeable sea breeze which usually sets in late in the afternoon, and is delightfully refreshing to the inhabitants. At night the reverse effect takes place. The land radiating away its heat to the cold sky, becomes colder than the sea, and the air incumbent over it becoming specifically heavier, flows out seawards, producing the land breeze. The periodical winds called *monsoons* are produced by the same cause acting on a larger scale; that is to say, by the warming of the interior of a continent during summer, and its cooling during winter.

The origin of the *trade winds* is to be found in the heating of the equatorial regions by the sun's rays. The air in these regions consequently ascends, and heavier air rushes in from both sides to supply its place, while the heated air which has ascended spreads

out laterally, producing an upper current in the opposite direction to that beneath. Were the earth stationary, and uniformly heated all round the equator, the winds thus produced would be due north and due south. The cold air from the polar regions would flow directly towards the equator, and the heated air from the equatorial regions would flow back to the poles. But the rotation of the earth, which gives to places near the equator a greater velocity from west to east than those far from it, causes an apparent motion of the air from east to west. Hence the trade winds in the northern hemisphere blow from the N.E., and those in the southern hemisphere from the S.E. They extend generally to about 28° on each side of the equator, but vary their limits according to the season of the year, moving northwards and southwards with the sun. They are separated by an equatorial belt of calms and variable winds about 6° in breadth. In the temperate zones there is a constant struggle between the polar current of air, which feeds the trade wind, and the returning equatorial current or counter-trade, the latter in general predominating, producing a S.W. wind in the northern temperate zone, and a N.W. wind in the southern. The descent to the surface of the earth of the counter-trade, which at the commencement of its course is an upper current, must be ascribed to the cooling and consequent increase of specific gravity, which it experiences in the upper regions of the atmosphere.

The *velocity* of the wind is usually from two to twelve miles an hour, the former producing a light air, the latter a stiff breeze. The highest winds on shore, in these latitudes, seldom exceed about thirty miles an hour. The *pressure* exerted on a surface directly perpendicular to the wind is proportional to the square of the velocity, and if the one be reckoned in lbs. per square foot, and the other in miles per hour, the pressure is approximately equal to 1-400 of the square of the velocity.

Much attention has been of late paid to the subject of *cyclones* or *rotatory storms*. In the southern hemisphere these storms *always* revolve in the *same direction as the hands of a watch lying with its face upwards*; while in the northern hemisphere they *always* revolve in the opposite direction. The centre is always characterized by very low barometer.

The *hurricanes* of the tropics, which blow with a violence unknown in temperate regions, belong to the class of cyclones; and in those regions where they are most frequent, they have regular tracks along which they always move, subject to comparatively small deviations. Their diameters are usually from 100 to 300 miles, and the motion of the centre is from two to forty miles an hour.

Rain occurs whenever the temperature of a mass of air is lower than its dew-point. The rain will of course be heaviest when the dew-point is high and the temperature low; in other words, when a mass of air heavily laden with moisture is cooled to a very low degree. These conditions are most completely fulfilled in mountainous districts near the sea, where the wind, laden with moisture from the sea, becomes chilled by the cold mountain tops. In the Andes of Patagonia 13 feet of rain have been observed to fall in forty-one days, and at Cherraponjie in the Khasyah mountains, east of Calcutta, about 540 inches

fall annually during the S.W. monsoon, from May to August inclusive. The mean annual rain-fall in Great Britain is about 30 inches, the wettest portion being the hill districts of Cumberland and Westmoreland, and the western highlands of Scotland, and the driest being the eastern counties of England.

When the dew-point of a mass of air is below freezing point, *snow*, instead of rain, is formed on its being cooled below this point. *Hail* is formed by the freezing of rain-drops during their descent.

The identity of *electricity* with the lightning flash was first established by Franklin. It is now known that electricity is present in the atmosphere at all times, though the mode of its production must still be regarded as uncertain. It is probable that the frequent association of heavy rain with thunderstorms is due to the fact that air, when laden with globules of water, acquires the power of conducting electricity, which it does not possess in their absence. The probability of lightning seems to be in proportion to the amount of vapour and the suddenness of its condensation. In confirmation of this view, it may be remarked that heavy rain, even when unaccompanied by lightning or thunder, is always accompanied by the manifestation of atmospheric electricity of unusual strength. The writer has on several occasions obtained sparks, during heavy rains or snow, from an insulated metallic vessel which was discharging water through a projecting pipe. [ELECTRICITY.]

In fine weather, and also during fog, atmospheric electricity is almost invariably positive. In showery weather it is generally positive and negative alternately. Its strength is extremely variable, changing generally by some twenty per cent. of its total amount every two or three minutes.

We must now give some account of *meteorological instruments*, and the usual *modes of observation*. Two meteorological societies, the British and the Scottish, have now been in existence for several years. Their observers are scattered over the length and breadth of the British Isles, and their records are despatched every month to head-quarters, where they are compared and published.

The instruments chiefly employed are THERMOMETERS, BAROMETERS, RAIN-GAUGES, and ANEMOMETERS.

The ordinary mercury *thermometer* is employed for ascertaining the temperature of the air at any given time. It is placed at the height of four or five feet from the ground, in the open air in the shade, protected from rain, but not from wind. The principal difficulty in the way of ascertaining the temperature of the air with accuracy is the disturbing effect of radiation from the ground and surrounding objects. Perhaps the best practical way of observing the temperature is to place the thermometer in the interior of a double box (i.e., a box within a box), the sides being louver-boarded, and the top furnished with a ventilator.

The highest and lowest temperatures of the air are observed by means of self-registering instruments. The minimum thermometer (for lowest temperature) usually employed is an alcohol thermometer, having its tube horizontal, and a glass float, which is carried backward by the alcohol when the temperature falls, and is left behind when it rises. Of maximum thermometers (for highest temperature), there are two

or three distinct kinds in general use. Perhaps the most common is that which consists of a mercury thermometer, with tube horizontal, and containing a small stick of steel called the index, which is pushed forward by the mercury when the temperature rises, and is not drawn back when it falls. Self-registering thermometers are usually observed once a day, and are reset immediately after the observation. The proper position for them is the same as for the ordinary thermometer above mentioned. The same position is also proper for the wet-bulb thermometer, which consists of an ordinary mercury thermometer, with a piece of wet muslin tied over its bulb. Some keep it constantly moist by means of a cotton wick communicating with a vessel of water. The readings of this thermometer, taken in conjunction with those of an ordinary thermometer, furnish data for computing the humidity of the air.

A thermometer exposed to the sun's rays is also frequently employed. Its bulb is usually blackened, to increase the absorption of heat, and a still higher temperature is obtained by inclosing the blackened bulb in an outer case of transparent glass with a space of air between. This outer case serves to exclude the action of wind upon the bulb, and thus leaves an effect dependent on radiation alone.

The *barometer* employed is of the simplest kind; the mechanism of the wheel-barometer, so commonly used as a weather glass, being incompatible with accuracy. The barometer used for scientific purposes is simply a vertical glass tube of not less than 3-10ths inch internal diameter, filled in its lower portions with mercury, and plunged in a cistern of mercury to which the air has free access; while the upper portion of the tube contains the nearest possible approach to a vacuum. The whole is inclosed in a brass case on which the scale is engraved. The observer first adjusts the level of the mercury in the cistern, so that its upper surface corresponds with the zero point of the scale, and he then observes which point on the scale corresponds with the upper surface of the column of mercury in the tube. The reading is taken, by means of a vernier, to the hundredth, or in some instruments to the thousandth of an inch; but this reading, which expresses the height of a column of mercury whose pressure equals that of the atmosphere, requires to be corrected for the different specific gravity of mercury at different temperatures. The specific gravity at the temperature 32°, the freezing point of water, is the standard to which the reduction is made. In comparing barometric indications at different localities, account must be taken of difference of level; for the atmospheric pressure being proportional to the weight of the superincumbent air, of course diminishes as we ascend. This difference amounts, roughly speaking, to a tenth of an inch for every ninety feet of difference in level. The mode of allowing for this difference, which is commonly adopted in the publication of results from a number of places, is to reduce the observed pressures to sea-level; that is, to calculate what would be the pressure at each place at the bottom of a shaft sunk to the mean level of the sea.

Rain-gauges, used for measuring the depth of rain-fall, are of various kinds, but they agree in having a horizontal circular orifice for receiving the rain as it falls. The upper part is usually cylindrical, from

three inches to a foot in diameter, and made of thin metal (copper, tin, or zinc). They are placed at various heights, from three inches above the ground to the tops of buildings, and it is found that as the height is diminished, the quantity of rain received is greater—a phenomenon whose cause is still disputed.

Of *anemometers*, or wind-gauges, the best is that invented by the Rev. Dr. Robinson, of Armagh, consisting of four hemispherical cups of thin metal attached to the extremities of four horizontal arms. When the wind blows it strikes against the hollow of the cup or cups on one side, and against the back of those on the other. The effective pressure is much greater against the former than against the latter, and rotation is consequently produced. The four arms are in a horizontal plane, and are attached to a vertical axis which turns with them, the number of revolutions being indicated by wheels precisely similar to those of a gas meter. Dr. Robinson found, both by theory and experiment, that the velocity of the centre of any cup is always one-third of the velocity of the wind; hence the instrument is available for observing either the velocity of the wind at a particular time, or the total horizontal movement of the air during a lengthened period.

Most of the instruments which we have described have been adapted to *self-registration*, and at the Royal Observatory, Greenwich, photographs are taken daily, showing the fluctuation of temperature and barometric pressure continuously throughout the twenty-four hours. This object is attained by causing a piece of photographically prepared paper to move horizontally at a constant slow rate; while a lamp, whose light is concentrated by a cylindric lens, illuminates the paper *above* the column of mercury in barometer or thermometer, that portion of the paper which is immediately behind the mercury being screened by the mercury from the light. The line separating the discoloured from the unaffected portion of the paper accordingly shows how the mercury has risen and fallen during the day.

Of late years an attempt has been made to apply meteorological science, on a large scale, to the *prediction of weather*, and especially to the *prediction of storms of wind*. Telegraphic reports of the state of the weather, and the readings of meteorological instruments, are despatched daily from about eighteen places round our own coasts, a few French ports, and Heligoland, to the Meteorological Department of the Board of Trade, in London, lately under the direction of the much-lamented Admiral Fitzroy. This is done at 10 a.m., and copies of the information thus received, arranged in a tabular form, together with forecasts of weather founded thereon, are sent an hour afterwards to the *Times* (for second edition), *Lloyd's*, and the *Shipping Gazette*; to the Board of Trade, Admiralty, and Horse Guards. Soon afterwards similar reports are sent to other afternoon papers; and late in the day, copies, more or less modified in consequence of telegrams received in the afternoon, are sent out for the next morning's early papers. When a storm is apprehended, orders are telegraphed to the *storm-signal* stations to hoist the proper signal. Of these signals there are different kinds, to indicate the direction from which the wind is expected to blow, and the degree of violence; and the order sent indicates which signal is to be hoisted.

Of a great number of shipmasters whose opinions as to the practical value of the storm-signals were individually asked in a recent parliamentary inquiry, the great majority were strongly favourable.

The method pursued in forming these forecasts cannot be completely explained in moderate compass. The following account is abridged from an official report by Mr. Babington, the present head of the Meteorological Department of the Board of Trade:—

‘Considering that there are two constant principal wind-currents, N.E. and S.W., of which the characteristics, especially with regard to temperature and degree of moisture or dryness, are totally distinct, all varieties of wind and weather in these latitudes may be traced to the operation of these two main currents—singly, in combination, or in antagonism; at times running in parallel lines, but in opposite directions; frequently superposed; and occasionally meeting at various angles of incidence. Upon the relative prevalence or failure of either or both of these currents all conditions of weather appear to depend.

‘It is clear that changes must begin at some places earlier than at others; and the observations telegraphed daily to this department from the outposts afford the means of forming a very good opinion respecting the nature and probable course of such changes. One or two examples must suffice, although the various examples that might be given are numerous; as also are the disturbing causes which must be taken into account.

‘Suppose a northerly (E.N.E.—N.N.W.) current to have been prevailing generally over this country with fine weather, the barometers at all the outposts during the continuance of such weather will have been steady, or slowly rising, nearly uniform, or slightly higher at the northern than at the southern stations; there will have been much evaporation, and the sky will have been comparatively clear and free from cloud, while the temperatures, when free from the influence of radiation, will have been somewhat below the average.

‘Suppose, now, the northern barometers rise rapidly above the average, while the temperature remains low and the sky clear. This is an indication of more wind from a northern quarter, but probably without rain. Should, however, the southern barometers fall at the same time, while the temperatures in the south are much higher than in the north, the wind will probably increase to a gale from a northern quarter, and a sudden chilling of the atmosphere in the south will ensue, causing rain.

‘The first approach of a southerly current is usually indicated by a diminution of pressure (falling barometers) in the north and west, caused by a failure of the polar current; the upper clouds are seen to be passing from the south, and the temperature increases.

‘Occasionally a temporary failure of both currents takes place. We may have very low barometers, but for a day or two little or no wind. Such a state of things, however, never continues long. It is then

especially necessary to watch for the first signs of approaching wind. The first indication is usually an increase of pressure in the direction from which the wind is coming. Should the French barometers rise rapidly, or stand (say) an inch higher than in Scotland, the result will be a gale from the southward. Should both the French and the Scotch barometers rise rapidly, while in Ireland and central England the pressure continues very low, we may feel sure that both currents are approaching in force, and that the collision will be violent, causing much rain, and (according to the angle of incidence), either south-west and north-west gales, or a cyclonic movement, which, experience has shown, will probably advance in an easterly or north-easterly direction. On the other hand, should the increase of pressure be gradual and general, the combination of the two currents will be gradual also, and though there may be rain, the winds will not be violent.

‘There are a few grand rules, which, though not always free from disturbing causes, may be considered as generally holding good:—

‘1st. The essentially distinct characteristics of the two main currents should never be forgotten.

‘2nd. The direction of wind is usually from the place of high barometer towards the region of low barometer.

‘3rd. The force of wind is usually proportional to the differences of barometric pressure, not to the actual pressure.

‘4th. It was believed by Admiral Fitzroy that there exists a lateral transference of the whole body of atmosphere eastward.

‘Electrical and auroral occurrences should be carefully watched; and the influence of high land, &c., must be borne in mind.’

There is another point in connection with forecasting in which the late Admiral Fitzroy took great interest, namely, the frequency with which important atmospheric disturbances have been preceded by disturbances on electric wires above ground, and also on submarine wires.

Of the Plates which accompany this article, Plates 1, 2, 3, 4, are devoted to the appearances presented by clouds under different circumstances as respects sunlight, mutual position, and the position of the spectator. See also the article CLOUDS. Plate 5 exhibits a system of isothermal lines, whose significance we have already explained. The system of broken lines which accompany them are isogeothermic lines, that is, lines of equal surface temperature; for instance, the broken line marked 65° 75° passes over those portions of land and sea in which the surface temperature of soil and sea, respectively, is 65° 75°. The isothermal lines, on the other hand, pass through those regions which have the same air-temperature. In both cases, the temperatures referred to are the mean annual temperatures. and their amounts are indicated in degrees of Fahrenheit’s scale.
